# MMREC: LLM Based Multi-Modal Recommender System

Jiahao Tian<sup>∗</sup> jtian83@gatech.edu Georgia Institute of Technology Atlanta, Georgia, USA

Zhenkai Wang<sup>∗</sup> kay.zhenkai.wang@utexas.edu The University of Texas at Austin Austin, Texas, USA

Abstract

The importance of recommender systems is growing rapidly due to the exponential increase in the volume of content generated daily. This surge in content presents unique challenges for designing effective recommender systems. Key among these challenges is the need to effectively leverage the vast amounts of natural language data and images that represent user preferences. This paper presents a novel approach to enhancing recommender systems by leveraging Large Language Models (LLMs) and deep learning techniques. The proposed framework aims to improve the accuracy and relevance of recommendations by incorporating multi-modal information processing and by the use of unified latent space representation. The study explores the potential of LLMs to better understand and utilize natural language data in recommendation contexts, addressing the limitations of previous methods. The framework efficiently extracts and integrates text and image information through LLMs, unifying diverse modalities in a latent space to simplify the learning process for the ranking model. Experimental results demonstrate the enhanced discriminative power of the model when utilizing multi-modal information. This research contributes to the evolving field of recommender systems by showcasing the potential of LLMs and multi-modal data integration to create more personalized and contextually relevant recommendations.

Keywords: Multi-Modality, Large Language Models, Recommender System, Deep Learning Recommendation Model, Personalization, Imbalanced Dataset Modeling

## 1 Introduction

Recommender Systems have become an integral component of modern digital ecosystems, playing a pivotal role in personalizing user experiences across various domains such as e-commerce, streaming services, social media, and more [\[16,](#page-8-0) [34,](#page-8-1) [35,](#page-8-2) [57,](#page-9-0) [64\]](#page-9-1). These systems aim to predict the preferences of users and suggest items that align with their tastes,

Jinman Zhao<sup>∗</sup> jinman.zhao@mail.utoronto.ca Univeristy of Toronto Toronto, Ontario, Canada

Zhicheng Ding<sup>∗</sup> zhicheng.ding@columbia.edu Columbia University New York, NY, USA

thereby enhancing user engagement and satisfaction. The foundations of the Recommender System can be traced back to collaborative filtering techniques, which leverage useritem interaction data to identify patterns and make recommendations. Over time, these systems have evolved to incorporate more sophisticated approaches, including contentbased filtering, hybrid methods, and context-aware recommendations, to address user data's growing complexity and scale.

The development of machine learning and deep learning has revolutionized nearly every field [\[1,](#page-7-0) [19,](#page-8-3) [24,](#page-8-4) [26,](#page-8-5) [42,](#page-8-6) [43,](#page-9-2) [59\]](#page-9-3), including recommender systems. These systems now benefit from large-scale models that can leverage vast amounts of data to extract complex relationships. Deep learning techniques, such as neural collaborative filtering (NCF), convolutional neural networks (CNNs), and recurrent neural networks (RNNs), have been employed to enhance the accuracy and robustness of Recommender System [\[6,](#page-7-1) [9,](#page-7-2) [21,](#page-8-7) [56,](#page-9-4) [65\]](#page-9-5). These models benefit from their ability to automatically learn feature representations from raw data, eliminating the need for manual feature engineering and improving predictive performance. Moreover, the use of attention mechanisms and transformer architectures has further advanced the capabilities of deep learning-based recommenders by allowing them to capture sequential and contextual information better [\[35,](#page-8-2) [64\]](#page-9-1).

Recently, Large Language Models (LLMs) like GPT-4 have shown immense potential in understanding and generating human-like text. In recommender systems, vast amounts of natural language data, such as user reviews and product information, are rich in valuable insights [\[31,](#page-8-8) [63\]](#page-9-6). Before the era of LLMs, Pretrained Language Model such as BERT [\[11\]](#page-7-3) was heavily used for processing text information . However, LLMs have demonstrated the potential to outperform BERT in terms of reasoning and understanding human language. By leveraging the processed information provided by LLMs, recommender systems can achieve a deeper understanding of user intents and preferences, leading to more personalized and contextually relevant recommendations. In this paper,

<sup>∗</sup>These authors contributed equally to this work.

we propose a novel LLM-enhanced deep learning framework with the following contributions:

- We developed a framework that efficiently extracts multi-modal information, such as text and images, from LLMs
- Information from different modalities is unified in a latent space, simplifying the learning process for the ranking model.
- We demonstrated how the use of multi-modal information can further enhance the discriminative power of the model, especially for improving false positive rate in the case of the imbalanced dataset.

The structure of the paper is as follows: Section [2](#page-1-0) introduces the latest developments in recommender systems and LLMs. Section [3](#page-1-1) briefly discusses the data used. Section [4](#page-2-0) presents our proposed framework and its key components. Section [5](#page-3-0) details the experimental setup and analysis. Finally, Section [6](#page-7-4) provides concluding remarks.

## <span id="page-1-0"></span>2 Related Work

## 2.1 Recommender System

Earlier work on Recommender Systems(RS) did not involve the extensive use of deep learning as seen in current approaches. For specifics, one can refer to [\[18\]](#page-8-9), which includes over 100 techniques from before 2017.

RS can be broadly categorized into personalized [\[53,](#page-9-7) [61,](#page-9-8) [62\]](#page-9-9) and group-based [\[27,](#page-8-10) [36,](#page-8-11) [38,](#page-8-12) [58,](#page-9-10) [60\]](#page-9-11) systems. Collaborative Filtering (CF) stands out as a prevalent technique. CF predicts a user's preferences or opinions by leveraging the collective insights from a large user base. Notable implementations include memory-based CF approaches such as those presented in [\[5\]](#page-7-5) and [\[3\]](#page-7-6), which utilize vector representations. Another prominent category is Model-based CF, which forecasts user preferences by analyzing the relationships between users and items. In recent years, the integration of graph neural networks like CNN [\[2\]](#page-7-7), GCN [\[23\]](#page-8-13), GraphSAGE [\[17\]](#page-8-14), and others have significantly enhanced model-based CF methods. These models have been extensively applied across various domains, with notable success in music, Point of Interest (POI), and book recommendations. For instance, the JODIE [\[28\]](#page-8-15) model has been influential in music recommendation, while Multi-GCCF [\[39\]](#page-8-16), and LightGCN [\[20\]](#page-8-17) have shown promising results in POI and book recommendation scenarios. Among these, LightGCN has emerged as a classic model in the RS field. The effectiveness of review text in RS has been a subject of debate. For example, [\[7\]](#page-7-8) argued that not all parts of reviews hold equal importance, leading them to propose an Aspect-based Neural Recommender (ANR) that focuses on more granular feature representations of items. Similarly, [\[29\]](#page-8-18) employed capsule neural networks to extract specific viewpoints and aspects from user and item reviews. Furthermore, [\[54\]](#page-9-12) developed a dual-encoder system using

CNNs, one for encoding news and the other for learning user profiles based on their interaction with clicked news.

#### 2.2 Large Language Models Reasoning

LLMs have demonstrated remarkable reasoning capabilities, particularly in benchmarks such as arithmetic [\[8,](#page-7-9) [32\]](#page-8-19) and commonsense [\[41\]](#page-8-20). These models have showcased an ability to understand and perform complex calculations, as well as to apply general knowledge about the world in a way that mimics human-like understanding. Many works show the power of prompting during reasoning with LLMs such as few-shot learning [\[4\]](#page-7-10), emotional prompt [\[30\]](#page-8-21) and Chain-of-Thought [\[25,](#page-8-22) [52\]](#page-9-13).

Recently, there has been a trend towards using LLMs for traditional tasks. For instance, [\[44\]](#page-9-14) employs in-context learning on GPT-3 for Relation Extraction(RE), achieving stateof-the-art (SOTA) performance on multiple test sets. [\[47\]](#page-9-15) adapts LLMs to the Named Entity Recognition (NER) task, aiming to bridge the gap between sequence labeling and text generation. This adaptation demonstrates how LLMs can be fine-tuned or prompted in innovative ways to handle tasks traditionally outside their direct training objectives. [\[55\]](#page-9-16) investigate the capabilities of LLMs in zero-shot information extraction scenarios, specifically examining the performance of ChatGPT in the NER task. By focusing on zero-shot learning, the study investigates ChatGPT's ability to identify and classify named entities within text and without any task-specific training data or fine-tuning. [\[51\]](#page-9-17) conducted the ability of LLMs to generate new financial signals. LLMs have also been employed for other tasks such as text summarization [\[14\]](#page-8-23) and sentiment analysis [\[40\]](#page-8-24).

## 2.3 LLM for Recommender Systems

Recent efforts in the domain of recommender systems have increasingly focused on the utilization of Language Models [\[13,](#page-8-25) [22,](#page-8-26) [50\]](#page-9-18). [\[12\]](#page-7-11) utilizes LLMs as the interface for recommender systems, facilitating multi-round recommendations. This enhances both the interactivity and the explainability of the system. [\[46\]](#page-9-19) proposed a three-step prompting strategy that substantially surpasses traditional simple prompting techniques in zero-shot settings. [\[48\]](#page-9-20) preprocess users' instructions and traditional feedback, such as clicks, using an instructor module to generate tailored guidance. [\[10\]](#page-7-12) conduct an evaluation to assess off-the-shelf LLMs for RS, analyzing them from point-wise, pair-wise, and list-wise perspectives.

#### <span id="page-1-1"></span>3 Data

#### 3.1 Source

In this study, we utilized a comprehensive dataset tailored for restaurant reviews analysis. This data is published in Kaggle<sup>[1](#page-1-2)</sup> and it is collected from Google reviews [\[45\]](#page-9-21). This dataset

<span id="page-1-2"></span><sup>1</sup><https://www.kaggle.com/>

comprises user-generated reviews for various restaurants. Each entry includes:

- a unique user ID
- the business ID of the restaurant being reviewed
- the review rating (ranging from 1 to 5, we consider a rating below greater or equal to 4 as a positive rating)
- the actual text of the review
- images uploaded by the user that are associated with the review.

# 3.2 Splitting

Our primary objective in this study is to analyze the impact of LLM summarization capabilities on feature engineering, rather than addressing the cold start problem. Therefore, during data pre-processing, we exclude any business ID or user ID that has only one associated review. This ensures that after splitting the dataset into training and test sets, no user or business in the test set will face the cold start issue, allowing us to directly apply features derived from the training set to the test set reviews. After eliminating these data points, we set the train-test split ratio to 3:1. We then perform random sampling with the condition that every user and business ID in the test set must also exist in the training set. Eventually, the train set contains 50468 positive reviews and 6537 negative reviews, test set contains 15370 positive reviews and 2032 negative reviews.

# <span id="page-2-0"></span>4 Methodology

Our proposed model leverages deep learning techniques and the advanced reasoning capabilities provided by large language models (LLMs) to enhance the performance of the ranking model. We hypothesize that the summarization power of LLMs can significantly improve the discriminative capabilities of the ranking model, leading to more accurate and relevant recommendations.

In this section, we introduce the various components of our proposed LLM-enhanced Deep Learning Recommendation Model (DLRM). We detail the architecture, data preprocessing steps, feature engineering techniques, and the training process. Additionally, we discuss the integration of LLMs into the DLRM framework, highlighting how their contextual understanding and summarization abilities contribute to improved model performance.

# 4.1 DLRM and the base model

DLRM is a robust framework that leverages deep learning techniques for recommendation tasks [\[33\]](#page-8-27). DLRM has proven to be highly effective in personalization and recommendation scenarios, such as click-through rate (CTR) prediction [\[15,](#page-8-28) [37\]](#page-8-29). At its core, DLRM comprises three main components: the Bottom Multi-Layer Perceptron (MLP), the Feature Interaction module, and the Top MLP. The Bottom MLP is designed to process and extract signals from dense or

continuous features, learning essential patterns and representations. The Feature Interaction module then takes the embeddings of sparse or categorical features, along with the output of the Bottom MLP, to capture and model the interactions between all features comprehensively. Specifically, the output from the Bottom MLP and sparse embeddings are concatenated, and the inner product is calculated across all pairwise dimensions. Finally, the Top MLP combines the outputs from the Feature Interaction module and the Bottom MLP to make the final prediction, such as the click-through probability in our case.

As shown in Figure [1,](#page-3-1) we process the textual information contained in user reviews by converting each text review into an embedding using the sentence transformer. Specifically, we use MiniLM-L6-v2 model for all our experiments [\[49\]](#page-9-22). We then take the element-wise average across all dimensions to create user or business features. Similarly, each image contained in the user reviews or associated with a particular business is transformed into continuous data using ResNet50. Specifically, we extract the second-to-last layer to represent the images, capturing rich feature representations.

# 4.2 LLM summarization

To leverage the summarizing power of large language models (LLMs), we propose various methods to enhance the features fed into our model. In this section, we explain how the LLM-enhanced DLRM differs from the base model presented above.

- Dense Features: In addition to the continuous features used in the base model (e.g., the number of reviews a restaurant received, average rating), we utilize the LLM's reasoning ability to extract pricing information from user reviews. This enriched feature set provides a more comprehensive understanding of the restaurant being scored.
- Sparse Features: Instead of applying an element-wise average across embeddings from all textual reviews or images, we use the LLM to process and summarize the most important information from all reviews, obtaining an embedding for this summary alone. For images, we leverage the LLM's multimodal capabilities to interpret and summarize the information contained in the images, converting them into textual descriptions. This textual information is then processed in a similar manner to the reviews.

This approach offers several advantages:

- Reduction of Noise: By summarizing the most important information, we ensure that only relevant data is fed into the model, preventing irrelevant or noisy information from diluting important signals.
- Unified Embedding Technique: Since images are converted into textual descriptions, both reviews and images use the same embedding technique to transform

<span id="page-3-1"></span>

Figure 1. Base model for the restaurant recommendation task

them into continuous data. This ensures that features from different modalities are projected into the same latent space, enhancing the model's ability to understand and utilize the combined information effectively.

Besides the differences mentioned above, as shown in Figure [2,](#page-4-0) we also introduce an additional sparse feature into the model. Using the LLM, we categorize each restaurant into one of 11 categories. This categorical feature is then fed into the feature interaction module after the embedding layer.

#### 4.3 Dimension reduction

To mitigate the risk of overfitting caused by the high-dimensional outputs of both the sentence transformer (384 dimensions) and ResNet50 (2048 dimensions), we propose an upstream model for dimensionality reduction. This approach preserves meaningful information while addressing the potential increase in model parameters. Our method involves the following steps:

- Concatenate embeddings from both the text encoder and image encoder into a single tensor.
- Feed this combined tensor through a Multi-Layer Perceptron (MLP).
- The MLP outputs the probability of the outcome of interest (e.g., a positive review).

Importantly, we apply the same MLP used in training to the embeddings during the testing phase. This approach ensures effective dimensionality reduction while retaining the most crucial information for prediction. By implementing this technique, we balance model complexity and predictive power, enhancing the overall performance of our recommender system.

## <span id="page-3-0"></span>5 Experiement

#### 5.1 Parameter and Configuration

To evaluate the model's performance under different conditions, we experiment with various dropout rates, different weighted loss function and baseline vs proposed model.

- Dropout: is a regularization technique that helps prevent overfitting by randomly setting a fraction of input units to zero during training, specifically [0.1, 0.3, 0.5]
- weighted loss: This dataset is highly imbalanced with 1/8 of the datapoint is associated with false labels and rest are postive samples. In order to balance the impact of each class on the loss function, we also experiment with different weighted loss functions. Weights are normalized after calculated by following formulas:
	- Basic:

$$
W^{label} = 1 - \frac{Num^{label}}{Number}
$$
 (1)

<span id="page-4-0"></span>

Figure 2. LLM enhanced DLRM for the restaurant recommendation task

<span id="page-4-1"></span>

Figure 3. LLM user summary example.

– Square root:

$$
W^{label} = \sqrt{1 - \frac{Num^{label}}{Number}} \tag{2}
$$

Each training starts with learning rate as 0.01, utilizing Adaptive Moment Estimation for adaptive learning rate adjustment. In each epoch, we evaluate the model performance against the training set and test set and update the best model if the model has a better false positive rate against the test set. We start applying early stops after finishing the first 300 epochs. Training stops when there is no continuous improvement of the false positive rate in the last 50 epochs. We repeated each parameter set evaluation five times.

#### 5.2 Data Pre-processing

Our baseline model utilizes dense features and embedding features to predict the review rating.In constructing the following features, we exclude the current review to avoid bias. During training, for each data point (business\_id, user\_id, current review), we generate business features based on reviews from other users. This ensures that the current user's review does not influence the feature construction. Similarly, we generate user features based on reviews users provided to other businesses. During testing, we use the entire training dataset to construct features for the testing data points.

• Dense Features:

			accuracy	fp rate	loss
model	wgted loss	dropout			
proposed	basic	0.10	91.62%	2.02%	2.7
		0.30	88.11%	4.14%	4.08

		0.30	91.89%	31.74%	7.66
		0.50	91.83%	31.79%	7.64
	sqrt root	0.10	92.96%	35.26%	14.57
		0.30	93.26%	35.66%	12.62
		0.50	93.47%	37.58%	12.59

- Number of Reviews for the Business: The total number of reviews received by current business.
- Average Rating from the User: The average rating given by the user across all their reviews.
- Average Rating for the Business: The average rating received by the business across all reviews.
- Embedding Features:
	- User Review Text Feature: All reviews written by the user are collected and converted into 384 dimensional embedding vectors using the sentence transformer. An average pooling operation is then applied to these vectors to produce a single 1x384 vector representing the user's review text feature.
	- Business Review Text Feature: Similarly, all reviews received by the business are collected and

converted into multiple 384-dimensional embedding vectors, then average pooling is used to generate a single 384-dimensional embedding vector.

– Review Image Feature: Firstly, we use each image as input for a pre-trained reset-50 model, then extract features from the second-to-last layer. Each image generates a 1x2048-dimensional embedding vector.All image embedding vectors for a business are collected, and average pooling is applied to obtain a single embedding vector. Finally, we concatenate the business review text feature, user review text feature, and review image feature into a single big vector. This vector is then passed through a upstream model to reduce its dimension to 32.

Compared to the baseline model, we add new dense feature: Price Tag, and a sparse Feature: Restaurant Category, into the proposed model. In addition, we replace all embedding features with new ones generated with the help of LLM and multi-modal model.

- All following prompt engineering are using the GPT 3.5-turbo-1106 model.
- Dense Features:
	- Price Tag Feature: Use LLMs to analyze reviews for a business. We use the prompt: "Can you tell me if the price is over-rice, fair price, low price from reviews for this restaurant. Give me just the category ". There can be a case that there is no clear indication of the price level in review. Therefore after some data post-processing, we generate a price tag categorized as fair price, overpriced, cheap price, or none for each restaurant
- Sparse Features:
	- Restaurant Category Feature: Similar to the price tag feature, we use prompt "can you tell me what kind of restaurant this is from these reviews for the restaurant. Return me in this format:'type'". This prompt helps generate the best description of the restaurant category based on reviews. Given the limitation of the current LLM model, the result is not always a single restaurant type, usually a brief summary of the food style presented in reviews. Therefore, we generate each restaurant a list of subtypes. There are 179 distinct types and the maximum number of subtypes for a restaurant is 11. In the pre-processing step, all subtype tensors were padded to the length of 11, and the padding value is set to 179 (i.e. embedding table contains 180 distinct values and the last one is padding idx).
- Embedding Features with LLM:
	- With the help of LLM, we are able to get a summary of review with prompts shown in Fig [3](#page-4-1) to summarize all reviews written by the same user,

then convert the summary into an embedding vector representing the user. Similarly, we can get the embedding vector for a single business. We concatenate the business review summary features and user review summary features into one big vector. This vector is then passed through an upstream model to reduce its dimensionality of vector to 32.

- In addition, we rely on a multi-modal model (BLIP 2) to produce textual information from images through unconditional image captioning, producing objective descriptions for the images as shown in Fig [4.](#page-6-0) Each image is converted to one description sentence and then is transformed into anembedding vector. Average pooling is used to combine these vectors to create a comprehensive image feature representation for the restaurant. The averaged vector is then passed through an upstream model to reduce its dimensionality to 32.
- By concatenating the text vector and image vector together, we form the embedding features for the proposed model.

<span id="page-6-0"></span>

#### 5.3 Result

- Compared to the baseline model, the proposed model achieves a much better false positive rate in both the train set and the test set. According to Table 1, The best model against the train set is the proposed model with basic weighted loss and 0.1 dropout rate, the false positive rate is around 2%.
- The model with the highest accuracy is the baseline model with a 0.5 dropout rate and square root weight. It achieves 93.47% accuracy with a 37.58% false positive rate against the test set as shown in Table 2.
- Regarding the performance of the false positive rate against the test set, see Table 2, the best model turns

out to be the proposed model with basic weighted loss and 0.5 dropout rate. It achieves a 18.16% false positive rate while accuracy on the test set still reaches 83.48% we obtain a 19.4% improvement in the false positive rate at the expense of 10% decrease in accuracy

## 5.4 Analysis

We observed that when square root weighting is applied, there is a tendency for the false positive rate to increase. This is likely due to the model's focus on minimizing the overall error, potentially at the expense of higher precision.

In the proposed model, we observe a clear over-fitting with a lower dropout rate, which, paradoxically, results in increased accuracy and a reduced false positive rate. Although the model exhibits over-fitting, the aim of this paper is not to fine-tune the model to achieve optimal performance but to leverage the Large Language Model (LLM) summarization capabilities.

In the context of ranking and recommendation, it is crucial to avoid recommending items that do not match customers' preferences, which means a high false positive rate is unacceptable. In most practical applications, RS shows users a list of top N items. A lower false positive rate ensures that the recommendations are more aligned with the users' tastes and top 1 accuracy becomes less important. Usually, top N accuracy is high enough. In our experiment, the baseline model tends to label data as positive which results in higher accuracy due to the imbalanced dataset, and performs worse in identifying false samples. Therefore, instead of focusing on accuracy, we consider the proposed model to be better than the baseline model given its superior performance on a low false positive rate.

The significant reduction in the false positive rate observed in the proposed model can be attributed to the powerful ability of Large Language Models (LLMs) in summarizing reviews. LLMs, trained on vast and diverse corpora, possess extensive knowledge and nuanced understanding of language, enabling them to distill complex information effectively. When tasked with generating features like price levels or restaurant types from multiple reviews, LLMs can synthesize and summarize data, extracting relevant details and insights that might be challenging to identify through traditional methods. This process not only enhances the original information by integrating the contextual and experiential knowledge embedded in the reviews but also enriches the dataset with features that are informed by the broader understanding LLMs have acquired during their own training.

In addition, LLMs are good at extracting and emphasizing critical and repeated information in various reviews. By using prompts to summarize reviews, LLM helps provide a more accurate and representative summary of the sentiments and opinions expressed by users. This summarization power ensures that the model captures the essential features that

distinguish different users and restaurants, leading to more precise recommendations. In contrast, the baseline model employs a simpler approach by averaging the embedding vectors of all reviews. This method tends to dilute the information because it treats all reviews equally, regardless of their quality or relevance. Consequently, the baseline model is prone to incorporating a lot of noise into the embeddings, which can obscure the critical information needed to make accurate predictions. This noise makes it difficult for the model to effectively differentiate between user preferences and restaurant characteristics, resulting in a higher false positive rate.

In addition, the proposed model leverages the multimodal model (BLIP2) and its description ability to identify multiple food items listed in review images, helping the model to discriminate between various users and restaurants. By contrast, the baseline model relies on the image classification model(resnet), which has limitations in identifying multiple objects within the image, especially when dealing with multiple types. Image classification models alone fail to capture the semantic meaning within images, making the extracted signals less powerful when fed to the recommender.

# <span id="page-7-4"></span>6 Conclusion

In this paper, we have proposed an innovative framework that harnesses the reasoning and summarization capabilities of LLMs to process multi-modal information effectively. Our research demonstrates the significant potential of integrating multi-modal data to enhance the performance of deep learning-based recommender systems, particularly in scenarios involving imbalanced datasets.

The utilization of LLMs enables the projection of features from diverse modalities into a unified latent space, facilitating more efficient model learning and convergence. Specifically, our approach leverages LLMs to:

- Summarize user review texts, capturing nuanced user behaviors and preferences.
- Generate descriptive text for images, extracting implicit knowledge about businesses and products.

This novel method allows for the transformation of imagebased information into textual data, which can then be processed using the same text encoder employed for user reviews. Consequently, both image-derived and text-based features are represented in the same latent space when fed into the model, ensuring a more cohesive and comprehensive input.

Our findings indicate that the incorporation of these LLMgenerated signals leads to substantial improvements in model performance. We hypothesize that this enhancement is particularly pronounced due to two factors:

• The ability to extract valuable insights from negative reviews, which often contain critical information for recommendation systems.

• The summarization capabilities of LLMs, which ensure that essential information is distilled and preserved, rather than diluted during the averaging process typically employed in traditional approaches.
