

# UAV-Enabled Integrated Sensing and Communication in Maritime Emergency Networks

Bohan Li, *Member, IEEE*, Jiahao Liu, Yifeng Xiong, *Member, IEEE*, Junsheng Mu, Pei Xiao, *Senior Member, IEEE*, Sheng Chen, *Life Fellow, IEEE*

**Abstract**—With line-of-sight mode deployment and fast response, unmanned aerial vehicle (UAV), equipped with the cutting-edge integrated sensing and communication (ISAC) technique, is poised to deliver high-quality communication and sensing services in maritime emergency scenarios. In practice, however, the real-time transmission of ISAC signals at the UAV side cannot be realized unless the reliable wireless fronthaul link between the terrestrial base station and UAV are available. This paper proposes a multicarrier-division duplex based joint fronthaul-access scheme, where mutually orthogonal subcarrier sets are leveraged to simultaneously support four types of fronthaul/access transmissions. In order to maximize the end-to-end communication rate while maintaining an adequate sensing quality-of-service (QoS) in such a complex scheme, the UAV trajectory, subcarrier assignment and power allocation are jointly optimized. The overall optimization process is designed in two stages. As the emergency area is usually far away from the coast, the optimal initial operating position for the UAV is first found. Once the UAV passes the initial operating position, the UAV's trajectory and resource allocation are optimized during the mission period to maximize the end-to-end communication rate under the constraint of minimum sensing QoS. Simulation results demonstrate the effectiveness of the proposed scheme in dealing with the joint fronthaul-access optimization problem in maritime ISAC networks, offering the advantages over benchmark schemes.

**Index Terms**—Maritime emergency network, multicarrier-division duplex, integrated sensing and communication, unmanned aerial vehicle

## I. INTRODUCTION

Maritime rescue is never an easy task. Apart from natural factors, the limited capability of maritime communication and sensing (CAS) is the main challenge rendering the maritime rescue extremely difficult [1]. Without sufficiently high data rate communications and accurate sensing, the fast and effective rescue carried out several kilometers away from the coast is infeasible. To this end, advanced maritime emergency networks have been

investigated. In particular, the Global Maritime Distress and Safety System (GMDSS) is the most widely used maritime rescue system at present, which is composed of terrestrial base-station (TBS) and satellite networks, to provide long-range coverage of maritime communication and positioning services [2]. However, subject to the long distance from TBS and satellite to emergency area, the GMDSS suffers from restricted data rate, low-resolution sensing and large latency, failing to meet the demand of wide-band communication and accurate sensing on the ocean.

By contrast, due to high flexibility and easy deployment, unmanned aerial vehicles (UAVs) are more competitive for constituting temporary emergency networks [3], and they can achieve higher transmission rate and enhanced communication coverage in the target area [4]. As for sensing, satellites and TBSs are better at searching the widely-unknown area, while UAVs are capable of quickly approaching the targets and implementing the high-resolution positioning and detection works once the location of the interested area is roughly known. Despite of these advantages, there is a paucity of works that leverage UAVs to simultaneously execute the emergency tasks of CAS on the ocean. This is mainly because at present concurrently employing both communication and radar equipments may impose significant energy burden on the UAV, leading to reduced mission period. However, it is not the case in the near future of 5G+/6G era, as the integrated sensing and communication (ISAC) technology will enable the UAV to simultaneously carry out CAS on a common hardware platform, thereby largely saving energy consumption [5].

### A. Related Works

1) *UAV-Aided MCNs*: To date, there have been many works studying the UAV-aided maritime communication networks (MCNs) [6]. The authors of [7–11] proposed various UAV trajectory/deployment optimization and resource allocation algorithms to achieve different objectives in MCN, such as optimizing the overall lifetime of ocean sensors [7], maximizing data collection capability of UAV [8], minimizing UAV's total energy consumption [9], maximizing the effective eavesdropping rate for maritime security [10] and achieving the optimal system spectral efficiency [11]. However, the aforementioned works only consider the access link from the UAV to maritime users, but ignore the fronthaul link from the TBS to UAV. In fact, it is this fronthaul link that makes MCN different

from terrestrial networks in the presence of UAV-aided communications. More specifically, in terrestrial networks, with the aid of handover technique among cells or sufficient bandwidth, e.g., millimeter-wave band, the UAV can usually connect to a BS in its close proximity or have plenty of spectral resource. Hence the performance of fronthaul link can be maintained [12]. By contrast, for MCN, once the UAV flies far away from the TBS, its trajectory design and resource allocation must carefully consider the fronthaul link, as the degradation of which will highly hinder the achievable access rate. Considering the importance of fronthaul links in MCN, the authors of [13, 14] took the fronthaul constraint into account during UAV trajectory optimization. However, the proposed system applies the time-division strategy to implement fronthaul and access transmissions, which inevitably lowers the end-to-end data rate.

2) *UAV-Enabled ISAC*: Driven by its features of on-demand deployment and line-of-sight (LoS)-dominant channels, the UAV-enabled ISAC (UAV-ISAC) has garnered tremendous attention recently [5]. The authors of [15–20] studied the optimization of UAV trajectory/deployment and resource allocation to maximize the communication data rate or minimize the energy consumption while attaining adequate quality-of-service (QoS) for sensing. The sensing-centered schemes have also been proposed in [21, 22], where the optimization aims to maximize the accuracy of localization or detection subject to adequate communication QoS. Instead of dealing with single-objective optimization, the authors of [23, 24] concurrently optimized CAS relying on a weighted sum formulation. Here, three critical issues are worth further discussing.

First, in UAV-ISAC related papers, the metrics of sensing performance can be generally classified into two categories, i.e., mutual information (MI) based metrics [15, 17, 18, 23], and estimation-theoretic metrics [16, 20–22, 24], such as Cramér-Rao bound (CRB) and mean square error (MSE). Sensing MI is independent of the estimator, which makes system optimization more general, while estimation-theoretic metrics are only used for explicitly characterizing the performance of specific sensing task.

Second, in order to mitigate the interference between communication and sensing functions, most of the papers applied the time-division method to transmit communication signal and receive sensing echo at different time slots [15, 17, 19–21, 23], while the authors of [22, 25] proposed the subcarrier-division method such that CAS signals can be transmitted over orthogonal subcarriers. Both these two methods suppress the interference at the expense of time or frequency resource. In addition, the reference [18] implemented CAS using separate beams at the same time-frequency grid, but this approach inevitably causes residual digital-domain interference especially when targets and users are located at similar directions.

Third, only works [15, 16, 22] considered the fronthaul links. In particular, the authors of [15, 22] leveraged the fronthaul links to feed the sensed information back to the BS and the access links are only used for transmitting

sensing signal rather than the ISAC signal. Although the reference [16] indeed considered a scenario where the UAV implements the ISAC transmission and exchanges the CAS information with BS, it neglected the effect of fronthaul links during the system optimization.

## B. Motivations and Contributions

Against the above background, in this paper, we exploit the UAV-ISAC technique in maritime emergency networks, which has not been well-studied in open literature to the best of our knowledge. To make the application of UAV-ISAC in maritime emergency scenarios a reality, there are three challenges to be properly solved. (i) In order to improve the overall end-to-end CAS performance, the transmission frame structure, the integrated waveform, and the UAV's working mode have to be specifically designed. (ii) As the UAV is expected to implement real-time downlink (DL) communication and target sensing, it has to timely exchange the information with the TBS. Accordingly, the fronthaul link between the UAV and TBS must be properly considered. (iii) Unlike terrestrial scenarios, the performance of maritime CAS is highly dependent on the fronthaul and access links, resulting in a very complicated optimization problem. Hence, high-performance and low-complexity algorithm is crucial. This paper specifically addresses the above-mentioned challenges. Our novelties and contributions are summarized as follows.

- We design a UAV-ISAC scheme for maritime emergency networks. To mitigate the interference between DL communication and sensing echo signals and improve the end-to-end performance, the multicarrier-division duplex (MDD)-based ISAC waveform is proposed, in which the TBS-to-UAV fronthaul link, UAV-to-TBS fronthaul link, UAV-to-user DL link and UAV-to-target sensing link are assigned with four mutually orthogonal subcarrier sets. To compensate for the frequency loss caused by subcarrier-division operation, an advanced multi-stream frame structure is tailor-made for the proposed networks, thanks to the full-duplex characteristic of MDD.
- Considering the requirements of real-time CAS services in emergency area, the fronthaul links between the UAV and the TBS are practically modeled. Two different operating modes, decode-and-forward and amplify-and-forward, are applied at the UAV side to process the coded DL data from the TBS and the perceived sensing information to the TBS, respectively. The end-to-end sensing MI between targets and the TBS is derived to evaluate the sensing performance.
- In order to maximize the end-to-end DL rate while maintaining adequate sensing QoS, two sub-problems with respect to the optimization of UAV trajectory, power allocation at UAV and TBS sides, and subcarrier assignment within fronthaul and access links are presented. More specifically, considering the fact that the UAV cannot implement the CAS immediately

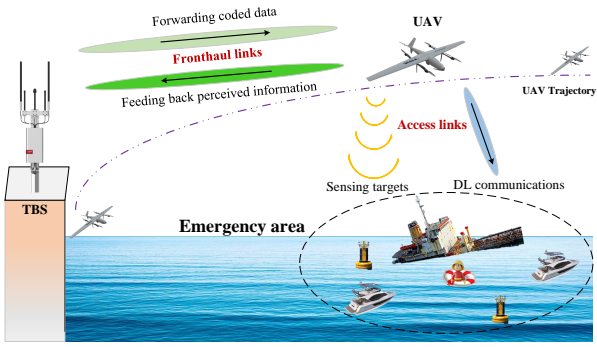

Fig. 1: UAV-ISAC enabled maritime emergency network.

after taking off due to the long distance away from the interested area, the first sub-problem aims to find the UAV's optimal initial operating location. Then, the second sub-problem maximizes the end-to-end DL rate under the constraint of minimum sensing MI during the mission period.

## II. SYSTEM MODEL

Consider a UAV-assisted maritime emergency network which includes a TBS, a fixed-wing UAV,  $U$  mobile users (ships requiring communication service) constituting the set  $\mathcal{U}$ , and  $J$  maritime targets (buoys, ships and other surface vehicles) constituting the set  $\mathcal{J}$ , as shown in Fig. 1. The on-demand UAV is deployed near the coast. Once the emergency occurs, the UAV will fly toward the designated area to constitute an airborne network. Equipped with ISAC technique, the UAV concurrently communicates with mobile users and senses targets at the same time and frequency band. The TBS is based along the coast and acts as the CPU establishing wireless fronthaul links with the UAV for forwarding the coded data to and receiving the perceived information from the UAV. To meet the stringent energy limit of UAV and avoid the overhead of extra radio-frequency (RF) components at the UAV, the fronthaul and access links share the spectrum.

Both the TBS and UAV operate in MDD mode. Specifically, all the subcarriers, defined by the index set  $\{m|m \in \mathcal{M}, |\mathcal{M}| = M\}$  within the frequency band, are coarsely classified into two blocks, i.e.,  $\mathcal{M}^D$  and  $\mathcal{M}^S$ , for implementing DL- and sensing-related tasks, respectively. The first  $M/2$  subcarriers within  $\mathcal{M}$  constitute  $\mathcal{M}^D$ , while the last  $M/2$  subcarriers constitute  $\mathcal{M}^S$ . At the  $n$ -th radio frame ( $R_F$ ),  $\mathcal{M}^D$  is further divided into  $\mathcal{M}_n^{CD}$  and  $\mathcal{M}_n^{DL}$ , which are used to transmit coded data at the TBS and implement DL communications at the UAV, respectively. Similarly,  $\mathcal{M}^S$  is further cut into  $\mathcal{M}_n^{SEN}$  and  $\mathcal{M}_n^{PE}$  for the UAV to carry out sensing and feed back the perceived signal to the TBS, respectively. Note that the way of fine division of  $\mathcal{M}^D$  and  $\mathcal{M}^S$  is flexible and time-variant, dependent on the specific scenario. Denote by  $\alpha_{n,m}^X \in \{0, 1\}$ ,  $X \in \{DL, SEN, PE, CD\}$ , the indicator of subcarrier assignment at the  $n$ -th  $R_F$ . If  $\alpha_{n,m}^X = 1$ , then  $m \in \mathcal{M}_n^X$ . According to the principle of MDD, we have

$$\alpha_{n,m}^{DL} + \alpha_{n,m}^{SEN} + \alpha_{n,m}^{PE} + \alpha_{n,m}^{CD} \leq 1, \forall m \in \mathcal{M}_n. \quad (1)$$

The frame structure is illustrated in Fig. 2, where the mission period  $T$  consists of  $N_t$   $R_F$ s, and each  $R_F$  includes  $N_s$  time slots. It is assumed that during each  $R_F$ , the UAV and mobile users are quasi-stationary and stay at fixed locations, while the channel state information (CSI) of fronthaul and access channels remain unchanged. Hence the transmission procedure during a single transmission period can be described as follows.

1) The UAV receives the pilots from users and derives the CSI of DL channels.

2) The UAV sends pilots and DL CSI to the TBS, who then estimates the CSI of the channel from the UAV to itself. Since the UAV and TBS leverage two orthogonal subcarrier sets within the same frequency band for two-way fronthaul transmissions, the two-way fronthaul channels exhibit time-domain reciprocity and frequency-domain correlation. Consequently, the TBS can derive the CSI of the channel from itself to the UAV.

3) The TBS sends coded data to the UAV based on the users' request, and feeds back the CSI of fronthaul channel to the UAV. In addition, as the TBS may have access to the rough image of emergency area via satellite remote sensing, it can provide the UAV with approximate coordinate of interested area so that UAV can implement quick sensing. Note that the delivery of CSI and auxiliary sensing coordinates can be achieved via control channels, and therefore will not affect system optimization.

4) The UAV decodes the data received from the TBS and forwards it to users. Depending on the *a-priori* information of targets' locations, the UAV leverages DL data to carry out sensing tasks.

5) The UAV pre-processes the echo signals and transmits the perceived information to the TBS for final sensing decision.

### A. Communication and Sensing Links

The UAV is equipped with  $R_{tx} = R_{tx}^l \times R_{tx}^w$  transmit and  $R_{rx} = R_{rx}^l \times R_{rx}^w$  receive uniform planar arrays (UPAs), which are placed parallel to the ground and sea surface. As shown in Fig. 2, at the  $t$ -th time slot of the  $n$ -th  $R_F$ , the integrated fronthaul, communication and sensing signal transmitted by the UAV can be expressed as (2) at the top of the next page, where  $\mathbf{w}_{SEN}^j[n, m]$  ( $x_{SEN}^j[n, t, m]$ ),

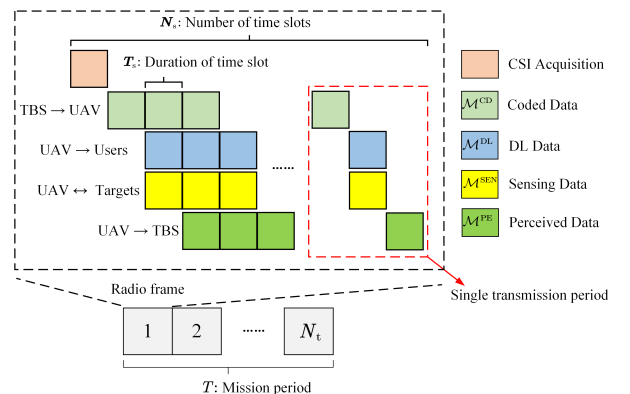

Fig. 2: Frame structure of UAV-enabled maritime emergency network operating on MDD mode.

$$\mathbf{s}[n, t] = \begin{cases} \mathbf{0}, & 1 \leq t \leq 2, \\ \sum_{m=1}^M \left( \alpha_{n,m}^{\text{SEN}} \sum_{j=1}^J \mathbf{w}_{\text{SEN}}^j[n, m] x_{\text{SEN}}^j[n, t, m] + \alpha_{n,m}^{\text{DL}} \sum_{u=1}^U \mathbf{w}_{\text{DL}}^u[n, m] x_{\text{DL}}^u[n, t, m] \right), & t = 3, \\ \sum_{m=1}^M \left( \alpha_{n,m}^{\text{SEN}} \sum_{j=1}^J \mathbf{w}_{\text{SEN}}^j[n, m] x_{\text{SEN}}^j[n, t, m] + \alpha_{n,m}^{\text{DL}} \sum_{u=1}^U \mathbf{w}_{\text{DL}}^u[n, m] x_{\text{DL}}^u[n, t, m] \right. \\ \left. + \alpha_{n,m}^{\text{PE}} \sum_{j=1}^J \mathbf{w}_{\text{PE}}^j[n, m] x_{\text{PE}}^j[n, t, m] \right), & t \geq 4. \end{cases} \quad (2)$$

$$\mathbf{r}_{\text{PE}}[n, t, m] = \begin{bmatrix} x_{\text{PE}}^1[n, t, m] \\ \vdots \\ x_{\text{PE}}^J[n, t, m] \end{bmatrix} = \begin{cases} \mathbf{0}, & 1 \leq t \leq 2, \\ \alpha_{n,m}^{\text{SEN}} \widetilde{\mathbf{W}}_{\text{SEN}}^{\text{H}}[n, m] \mathbf{H}_{\text{SEN}}^{\text{H}}[n, m] \mathbf{\Lambda}_{\text{SEN}}[n, m] \mathbf{x}_{\text{SEN}}[n, t, m] \\ + \mathbf{W}_{\text{SEN}}^{\text{H}}[n, m] (\mathbf{n}_{\text{UAV}}[n, m] + \mathbf{z}_{\text{SI}}[n, m]), & t \geq 3. \end{cases} \quad (3)$$

$\mathbf{w}_{\text{DL}}^u[n, m]$  ( $x_{\text{DL}}^u[n, t, m]$ ) and  $\mathbf{w}_{\text{PE}}^j[n, m]$  ( $x_{\text{PE}}^j[n, t, m]$ ) denote the precoders (data) for sensing target  $j$ , communicating with user  $u$  and sending the perceived information of target  $j$  back to the TBS, respectively, with each data having unit energy, i.e.,  $\mathbb{E} [|x[n, t, m]|^2] = 1$ . The transmit power of the UAV is constrained by  $\mathbb{E} [\|\mathbf{s}[n, t]\|^2] \leq P_{\text{UAV}}$ .

Since the UAV receives the coded data and sensing echo while transmitting integrated signal  $\mathbf{s}[n, t]$ , it suffers from self-interference (SI). We assume that the UAV can rely on passive cancellation methods (e.g., adding blockage between transmit and receive antennas [26]) or active cancellation methods (e.g., multi-tap RF canceller [27]) to provide sufficient analog-domain SI cancellation (SIC) such that the power of SI falls into the dynamic range of ADC. Then, thanks to the characteristic of MDD [28], the reception of coded signal is free from the digital-domain SI with the aid of fast Fourier transform (FFT) operation. As for the reception of echo signal, although the digital interference components of DL and perceived signal can be readily removed by FFT, the transmitted sensing signal directly arriving at the receiver gives rise to the digital-domain SI, which can be modeled as  $\mathbf{z}_{\text{SI}}[n, m] \in \mathbb{C}^{R_{\text{rx}}} \sim \mathcal{CN}(\mathbf{0}, \alpha_{n,m}^{\text{SEN}} \xi_{\text{SIC}} \sum_{j=1}^J \|\mathbf{w}_{\text{SEN}}^j[n, m]\|^2 \mathbf{I}_{R_{\text{rx}}})$ , where  $\xi_{\text{SIC}}$  denotes the SIC capability at the UAV taking account the analog- and digital-domain SI suppression, as well as the effect of path-loss between the transmitter and receiver.

At the UAV, the received echo signal reflected from target  $j$  at the  $m$ -th subcarrier is given in (3) at the top of the page, where  $\mathbf{x}_{\text{SEN}}[n, t, m] = [x_{\text{SEN}}^1[n, t, m], \dots, x_{\text{SEN}}^J[n, t, m]]^{\text{T}} \in \mathbb{C}^J$ ,  $\mathbf{\Lambda}_{\text{SEN}}[n, m] = \text{diag}(\mathbf{W}_{\text{SEN}}[n, m]) \in \mathbb{C}^{R_{\text{tx}} \times J \times J}$  with  $\mathbf{W}_{\text{SEN}}[n, m] = [\mathbf{w}_{\text{SEN}}^1[n, m], \dots, \mathbf{w}_{\text{SEN}}^J[n, m]] \in \mathbb{C}^{R_{\text{tx}} \times J}$  and  $\text{diag}(\cdot)$  denoting the block diagonal transformation,  $\widetilde{\mathbf{W}}_{\text{SEN}}[n, m] = [\widetilde{\mathbf{w}}_{\text{SEN}}^1[n, m], \dots, \widetilde{\mathbf{w}}_{\text{SEN}}^J[n, m]] \in \mathbb{C}^{R_{\text{rx}} \times J}$  with  $\widetilde{\mathbf{w}}_{\text{SEN}}^j[n, m] \in \mathbb{C}^{R_{\text{rx}}}$  denoting the echo combining vector for target  $j$ , and  $\mathbf{H}_{\text{SEN}}[n, m] = [(\mathbf{H}_{\text{SEN}}^1[n, m])^{\text{H}}, \dots, (\mathbf{H}_{\text{SEN}}^J[n, m])^{\text{H}}]^{\text{H}} \in \mathbb{C}^{R_{\text{tx}} \times J \times R_{\text{rx}}}$

is the concentrated sensing channels of targets with  $\mathbf{H}_{\text{SEN}}^j[n, m] \in \mathbb{C}^{R_{\text{tx}} \times R_{\text{rx}}}$  given in (4), while  $\mathbf{n}_{\text{UAV}}[n, m] \sim \mathcal{CN}(\mathbf{0}, N_0 \mathbf{I}_{R_{\text{rx}}})$  denotes the additive white Gaussian noise with  $N_0$  representing noise power spectrum density. As we assume that targets are sparsely distributed, the terms of inter-beam interference caused by transmit antenna sidelobes, i.e.,  $\{\widetilde{\mathbf{w}}_{\text{SEN}}^a[n, m] (\mathbf{H}_{\text{SEN}}^a[n, m])^{\text{H}} \mathbf{w}_{\text{SEN}}^b[n, m] x_{\text{SEN}}^b[n, t, m] | \forall a, b \in \mathcal{J} \text{ and } a \neq b\}$ , are omitted to facilitate analysis. Unlike the complex scattering environment around TBS, the channels between the UAV and maritime users and targets are dominated by LoS link. Therefore, the sensing channel  $\mathbf{H}_{\text{SEN}}^j[n, m]$  is given by

$$\mathbf{H}_{\text{SEN}}^j[n, m] = \sqrt{\frac{G_{\text{UAV}}^{\text{tx}} G_{\text{UAV}}^{\text{rx}} \lambda_m^2 \sigma_j^{\text{RCS}}}{(4\pi)^3 d_j^4[n]}} \varpi_{j,n,m} e^{-j2\pi\tau_j f_m} \times e^{j2\pi f_{\text{D},j} t_0} \boldsymbol{\alpha}_{\text{tx}}(\theta_j^{\text{tx}}[n], \phi_j^{\text{tx}}[n], m) \boldsymbol{\alpha}_{\text{rx}}^{\text{H}}(\theta_j^{\text{rx}}[n], \phi_j^{\text{rx}}[n], m), \quad (4)$$

where  $G_{\text{UAV}}^{\text{tx}}$ ,  $G_{\text{UAV}}^{\text{rx}}$ ,  $\lambda_m$ ,  $\sigma_j^{\text{RCS}}$ ,  $\tau_j$ ,  $t_0$ ,  $\varpi_{j,n,m} \sim \mathcal{CN}(0, 1)$ ,  $f_m$  and  $f_{\text{D},j}$  are the UAV transmitter and receiver antenna gains, wavelength, radar cross-section (RCS), path delay, symbol duration, complex gain, center frequency of the  $m$ -th sub-band and Doppler frequency, respectively. The Doppler and delay effects are assumed to be perfectly compensated through synchronization [17, 29]. The distance between the UAV and target  $j$  is given by  $d_j[n] = \|\mathbf{c}_{\text{UAV}}[n] - \mathbf{c}_j\|$ , where  $\mathbf{c}_{\text{UAV}}[n] = [x_{\text{UAV}}[n], y_{\text{UAV}}[n], z_{\text{UAV}}[n]]$  and  $\mathbf{c}_j = [x_j, y_j, z_j]$  denote the coordinates of the UAV and the  $j$ -th target at the  $n$ -th  $R_{\text{F}}$ , respectively. The fly height of the UAV is assumed to be constant. Moreover,  $\boldsymbol{\alpha}_{\text{tx}}(\cdot)$  and  $\boldsymbol{\alpha}_{\text{rx}}(\cdot)$  denote the UPA response vectors of the UAV transmitter and receiver, respectively.

During the  $t$ -th time slot of the  $n$ -th  $R_{\text{F}}$ , the DL communication signal of subcarrier  $m$  received at user  $u$  is given in (5) at the bottom of the page, where  $n_u[n, m] \sim \mathcal{CN}(0, N_0)$  and the DL communication channel is modeled as

$$\mathbf{h}_{\text{DL}}^u[n, m] = \sqrt{\frac{G_{\text{UAV}}^{\text{tx}} G_{\text{UE}}^{\text{rx}} \lambda_m^2}{(4\pi)^2 d_u^2[n]}} \varpi_{u,n,m} e^{-j2\pi\tau_u f_m} e^{j2\pi f_{\text{D},u} t_0}$$

$$y_u[n, t, m] = \begin{cases} 0, & 1 \leq t \leq 2, \\ \alpha_{n,m}^{\text{DL}} (\mathbf{h}_{\text{DL}}^u[n, m])^{\text{H}} \mathbf{w}_{\text{DL}}^u[n, m] x_{\text{DL}}^u[n, t, m] + \alpha_{n,m}^{\text{DL}} \sum_{u'=1, u' \neq u}^U (\mathbf{h}_{\text{DL}}^{u'}[n, m])^{\text{H}} \mathbf{w}_{\text{DL}}^{u'}[n, m] x_{\text{DL}}^{u'}[n, t, m] \\ + n_u[n, m], & t \geq 3, \end{cases} \quad (5)$$

$$\times \boldsymbol{\alpha}_{\text{tx}}(\theta_u^{\text{tx}}[n], \phi_u^{\text{tx}}[n], m) \in \mathbb{C}^{R_{\text{tx}}}, \quad (6)$$

in which  $\varpi_{u,n,m} \sim \mathcal{CN}(0, 1)$ ,  $d_u[n] = \|\mathbf{c}_{\text{UAV}}[n] - \mathbf{c}_u\|_2$  with  $\mathbf{c}_u = [x_u, y_u, z_u]$  denoting the coordinate of user  $u$ . As the subcarriers used for transmitting the coded, sensing and perceived signals are orthogonal to that used for DL transmissions, users only suffer from the co-subchannel multi-user interference.

### B. Two-Way Fronthaul Links

The TBS sends the coded data to the UAV using  $\bar{R}_{\text{tx}} = \bar{R}_{\text{tx}}^1 \times \bar{R}_{\text{tx}}^w$  transmit UPA. The UAV works as decode-and-forward relay [30] to firstly decode the received data and then carry out CAS tasks. Due to the complex sensing environment and limited computation resource, the UAV adopts amplify-and-forward method [31] in sensing task, that is, it only amplifies the received target echo and directly forwards it to the TBS for sensing data processing. To distinguish the perceived information of different targets, the TBS equips with  $\bar{R}_{\text{rx}} = \bar{R}_{\text{rx}}^1 \times \bar{R}_{\text{rx}}^w$  receive UPA.

The received coded data at the UAV on subcarrier  $m$  is given by (7) at the bottom of the page, where  $\widetilde{\mathbf{W}}_{\text{CD}}[n, m] = [\widetilde{\mathbf{w}}_{\text{CD}}^1[n, m], \dots, \widetilde{\mathbf{w}}_{\text{CD}}^U[n, m]] \in \mathbb{C}^{R_{\text{tx}} \times U}$  is the UAV combiner for receiving the coded data  $\mathbf{x}_{\text{CD}}[n, t, m] \in \mathbb{C}^U$  from the TBS. Under the TBS power constraint, the precoding matrix  $\mathbf{F}_{\text{CD}}[n, m] = [\mathbf{f}_{\text{CD}}^1[n, m], \dots, \mathbf{f}_{\text{CD}}^U[n, m]] \in \mathbb{C}^{R_{\text{tx}} \times U}$  satisfies  $\sum_{m \in \mathcal{M}} \alpha_{n,m}^{\text{CD}} \|\mathbf{F}_{\text{CD}}[n, m]\|_F^2 \leq P_{\text{TBS}}$ . Due to the strong LoS path and possible scatters around the TBS, the  $m$ -th subchannel between the TBS and UAV during the  $n$ -th  $R_{\text{F}}$  follows the Rician distribution, which can be expressed as (8), where  $d_{\text{TU}}[n] = \|\mathbf{c}_{\text{TBS}} - \mathbf{c}_{\text{UAV}}[n]\|_2$ ,  $\mathbf{c}_{\text{TBS}} = [x_{\text{TBS}}, y_{\text{TBS}}, z_{\text{TBS}}]$  is the coordinate of TBS,  $K_{\text{TU}}$  is the Rician factor, and each entry of the small-fading matrix  $\boldsymbol{\Psi}_{\text{CD}}[n, m]$  follows the distribution  $\mathcal{CN}(0, 1)$ .

As shown in Fig. 2, starting from  $t = 4$ , the TBS concurrently sends the coded data to the UAV and receives the perceived data from the UAV relying on two orthogonal subcarrier sets within the same frequency band, and hence experiences analog-domain SI. Similar to the signal processing at the UAV, we also assume that the TBS is able to provide sufficient analog-domain SIC such that the power of residual analog-domain SI falls into the ADC dynamic range. Then, the residual digital-domain SI can be efficiently canceled by FFT. Consequently, at the TBS receiver, the signal of the  $m$ -th subcarrier during

the  $t$ -th time slot of the  $n$ -th  $R_{\text{F}}$  is given in (9), where  $\widetilde{\mathbf{F}}_{\text{PE}}[n, m] = [\widetilde{\mathbf{f}}_{\text{PE}}^1[n, m], \dots, \widetilde{\mathbf{f}}_{\text{PE}}^J[n, m]] \in \mathbb{C}^{\bar{R}_{\text{rx}} \times J}$  is the combining matrix for receiving the perceived signal of targets,  $\mathbf{W}_{\text{PE}}[n, m] = [\mathbf{w}_{\text{PE}}^1[n, m], \dots, \mathbf{w}_{\text{PE}}^J[n, m]] \in \mathbb{C}^{R_{\text{tx}} \times J}$ ,  $\mathbf{n}_{\text{TBS}}[n, m] \sim \mathcal{CN}(0, N_0 \mathbf{I}_{\bar{R}_{\text{rx}}})$ , and  $\mathbf{H}_{\text{PE}}[n, m] \in \mathbb{C}^{R_{\text{tx}} \times \bar{R}_{\text{rx}}}$  has a similar form as  $\mathbf{H}_{\text{CD}}[n, m]$  in (8). As the subcarrier used for sensing is orthogonal to that for transmitting perceived signal, the subcarrier  $m'$  in  $\mathbf{r}_{\text{PE}}[n, t, m']$  is different from the subcarrier  $m$  in other terms. Furthermore, we assume  $|\mathcal{M}_n^{\text{SEN}}| = |\mathcal{M}_n^{\text{PE}}| = M/4$  and there are  $M/4$  subcarrier pairs, i.e.,  $\mathcal{M}_n^{\text{pair}} = \{(m, m') \mid m \in \mathcal{M}_n^{\text{PE}}, m' \in \mathcal{M}_n^{\text{SEN}}\}$ , to sense and forward target information, where any subcarrier in  $\mathcal{M}_n^{\text{PE}}$  and  $\mathcal{M}_n^{\text{SEN}}$  can only be paired for once.

### III. OPTIMIZATION PROBLEM DESIGN

By employing the MDD, the subcarriers used for DL communication, sensing and two-way fronthaul transmissions are mutually orthogonal, and the design of their corresponding digital beamforming vectors becomes independent. In order to focus on the joint optimization of UAV trajectory and MDD-enabled resource allocation to maximize the end-to-end communication rate of the proposed network while ensuring the sensing requirements, we adopt the conventional but highly efficient beamforming strategies to reduce the complexity of system optimization.

For two-way fronthaul links, due to the existence of non-negligible non-LoS channels, the ranks of  $\mathbf{H}_{\text{CD}}[n, m]$  and  $\mathbf{H}_{\text{PE}}[n, m]$  are much larger than the numbers of users and targets, respectively. Performing the singular value decomposition on  $\mathbf{H}_{\text{CD}}[n, m]$  and  $\mathbf{H}_{\text{PE}}[n, m]$  yields the effective channel matrices  $\bar{\mathbf{H}}_{\text{CD}}[n, m] = \mathbf{U}_{\text{CD}}[n, m] \boldsymbol{\Lambda}_{\text{CD}}^{1/2}[n, m] \mathbf{L}_{\text{CD}}^{\text{H}}[n, m]$  and  $\bar{\mathbf{H}}_{\text{PE}}[n, m] = \mathbf{U}_{\text{PE}}[n, m] \boldsymbol{\Lambda}_{\text{PE}}^{1/2}[n, m] \mathbf{L}_{\text{PE}}^{\text{H}}[n, m]$ , where  $\mathbf{U}_{\text{CD}}[n, m] \in \mathbb{C}^{\bar{R}_{\text{tx}} \times U}$  ( $\mathbf{U}_{\text{PE}}[n, m] \in \mathbb{C}^{R_{\text{tx}} \times J}$ ) and  $\mathbf{L}_{\text{CD}}[n, m] \in \mathbb{C}^{R_{\text{rx}} \times U}$  ( $\mathbf{L}_{\text{PE}}[n, m] \in \mathbb{C}^{\bar{R}_{\text{rx}} \times J}$ ) are the reduced unitary sub-matrices corresponding to the singular matrices of  $\boldsymbol{\Lambda}_{\text{CD}}[n, m] = d_{\text{TU}}^{-2}[n] \text{diag}(\eta_{\text{CD}}^1[n, m], \dots, \eta_{\text{CD}}^U[n, m])$  ( $\boldsymbol{\Lambda}_{\text{PE}}[n, m] = d_{\text{TU}}^{-2}[n] \text{diag}(\eta_{\text{PE}}^1[n, m], \dots, \eta_{\text{PE}}^J[n, m])$ ). In order to avoid inter-stream interference and maximize the capacity of fronthaul links, we set  $\mathbf{F}_{\text{CD}}[n, m] = \mathbf{U}_{\text{CD}}[n, m] \boldsymbol{\Sigma}_{\text{CD}}^{1/2}[n, m]$ ,  $\widetilde{\mathbf{W}}_{\text{CD}}[n, m] = \mathbf{L}_{\text{CD}}[n, m]$ ,  $\mathbf{W}_{\text{PE}}[n, m] = \mathbf{U}_{\text{PE}}[n, m] \boldsymbol{\Sigma}_{\text{PE}}^{1/2}[n, m]$ ,  $\widetilde{\mathbf{F}}_{\text{PE}}[n, m] = \mathbf{L}_{\text{PE}}[n, m]$ , where  $\boldsymbol{\Sigma}_{\text{CD}}[n, m] = \text{diag}(p_{\text{CD}}^1[n, m], \dots, p_{\text{CD}}^U[n, m])$  and  $\boldsymbol{\Sigma}_{\text{PE}}[n, m] = \text{diag}(p_{\text{PE}}^1[n, m], \dots, p_{\text{PE}}^J[n, m])$  denote the

$$\mathbf{y}_{\text{CD}}[n, t, m] = \begin{cases} \mathbf{0}, & t = 1, \\ \alpha_{n,m}^{\text{CD}} \widetilde{\mathbf{W}}_{\text{CD}}^{\text{H}}[n, m] \mathbf{H}_{\text{CD}}^{\text{H}}[n, m] \mathbf{F}_{\text{CD}}[n, m] \mathbf{x}_{\text{CD}}[n, t, m] + \widetilde{\mathbf{W}}_{\text{CD}}^{\text{H}}[n, m] \mathbf{n}_{\text{UAV}}[n, m], & t \geq 2, \end{cases} \quad (7)$$

$$\mathbf{H}_{\text{CD}}[n, m] = \sqrt{\frac{G_{\text{TBS}}^{\text{tx}} G_{\text{UAV}}^{\text{rx}} \lambda_m^2}{(4\pi)^2 d_{\text{TU}}^2[n]}} e^{-j2\pi\tau f_m} e^{j2\pi f_D t_0} \left( \sqrt{\frac{K_{\text{TU}}}{K_{\text{TU}} + 1}} \varpi_{n,m} \boldsymbol{\alpha}_{\text{tx}}^{\text{TBS}}(\theta^{\text{tx}}[n], \phi^{\text{tx}}[n], m) \boldsymbol{\alpha}_{\text{rx}}^{\text{H}}(\theta^{\text{rx}}[n], \phi^{\text{rx}}[n], m) + \sqrt{\frac{1}{K_{\text{TU}} + 1}} \boldsymbol{\Psi}_{\text{CD}}[n, m] \right) \in \mathbb{C}^{\bar{R}_{\text{tx}} \times R_{\text{rx}}}, \quad (8)$$

$$\mathbf{y}_{\text{PE}}[n, t, m, m'] = \begin{cases} \mathbf{0}, & 1 \leq t \leq 3 \\ \alpha_{n,m}^{\text{PE}} \widetilde{\mathbf{F}}_{\text{PE}}^{\text{H}}[n, m] \mathbf{H}_{\text{PE}}^{\text{H}}[n, m] \mathbf{W}_{\text{PE}}[n, m] \mathbf{r}_{\text{PE}}[n, t, m'] + \widetilde{\mathbf{F}}_{\text{PE}}^{\text{H}}[n, m] \mathbf{n}_{\text{TBS}}[n, m], & t \geq 4, \end{cases} \quad (9)$$

matrices of power allocation for coded DL data and perceived sensing data transmissions, respectively.

*Remark 1.* Due to the existence of strong LoS path between the TBS and UAV, for each subcarrier channel  $m$  used for transmitting perceived information, there is one singular value much larger than the others in  $\mathbf{\Sigma}_{\text{PE}}[n, m]$ . In this case, considering the effective detection of all the targets, the largest singular value with respect to  $|\mathcal{M}_n^{\text{PE}}|$  subcarrier channels is equally distributed to  $J$  targets. In other words, the largest singular value is not always placed at the first diagonal position of  $\mathbf{\Sigma}_{\text{PE}}[n, m]$ . Instead, the probability of its occurrence at every diagonal position is the same. By contrast, as the UAV adopts decode-and-forward to pass through the DL signal from TBS to users, we mainly concern the total channel capacity of each subcarrier channel  $\mathbf{H}_{\text{CD}}[n, m]$ , and therefore the position of the largest singular value inside  $\mathbf{\Sigma}_{\text{CD}}[n, m]$  is inconsequential.

To strike a balance between low-complexity and satisfactory performance, we adopt matched-filtering precoding for communication and sensing links. The communication precoding matrix is derived as  $\mathbf{W}_{\text{DL}}[n, m] = [\mathbf{w}_{\text{DL}}^1[n, m], \dots, \mathbf{w}_{\text{DL}}^U[n, m]] = [\boldsymbol{\alpha}_{\text{tx}}(\theta_1^{\text{tx}}[n], \phi_1^{\text{tx}}[n], m), \dots, \boldsymbol{\alpha}_{\text{tx}}(\theta_U^{\text{tx}}[n], \phi_U^{\text{tx}}[n], m)] \mathbf{\Sigma}_{\text{DL}}^{1/2}$ , where  $\mathbf{\Sigma}_{\text{DL}} = \text{diag}(p_{\text{DL}}^1[n, m], \dots, p_{\text{DL}}^U[n, m])$  is the DL transmission power allocation matrix. The sensing transmit and receive beamformers are implemented as  $\mathbf{W}_{\text{SEN}}[n, m] = [\boldsymbol{\alpha}_{\text{tx}}(\theta_1^{\text{tx}}[n], \phi_1^{\text{tx}}[n], m), \dots, \boldsymbol{\alpha}_{\text{tx}}(\theta_J^{\text{tx}}[n], \phi_J^{\text{tx}}[n], m)] \mathbf{\Sigma}_{\text{SEN}}^{1/2}$  and  $\widetilde{\mathbf{W}}_{\text{SEN}}[n, m] = [\boldsymbol{\alpha}_{\text{rx}}(\theta_1^{\text{rx}}[n], \phi_1^{\text{rx}}[n], m), \dots, \boldsymbol{\alpha}_{\text{rx}}(\theta_J^{\text{rx}}[n], \phi_J^{\text{rx}}[n], m)]$ , where  $\mathbf{\Sigma}_{\text{SEN}}[n, m] = \text{diag}(p_{\text{SEN}}^1[n, m], \dots, p_{\text{SEN}}^J[n, m])$  is the power allocation matrix for target sensing.

Intuitively, the end-to-end rate is related to the performance of both fronthaul and access transmissions. Denote by  $R_{\text{CD}}[n]$  and  $R_{\text{DL}}[n]$  the  $n$ -th  $R_{\text{F}}$  achievable rate of the TBS sending coded data to the UAV and the  $n$ -th  $R_{\text{F}}$  achievable rate of the UAV transmitting DL data to users, respectively. Based on (5) and (7),  $R_{\text{CD}}[n]$  and  $R_{\text{DL}}[n]$  can be expressed as follows

$$R_{\text{CD}}[n] = \frac{N_s - 1}{N_s} \sum_{m \in \mathcal{M}} \log \det \left( \mathbf{I}_U + \frac{\alpha_{n,m}^{\text{CD}} \mathbf{\Sigma}_{\text{CD}}[n, m] \boldsymbol{\Lambda}_{\text{CD}}[n, m]}{N_0} \right), \quad (10)$$

$$R_{\text{DL}}[n] = \frac{N_s - 2}{N_s} \sum_{m \in \mathcal{M}} \log \det \left( \mathbf{I}_U + \alpha_{n,m}^{\text{DL}} N_0^{-1} \mathbf{H}_{\text{DL}}^{\text{H}}[n, m] \right. \\ \left. \times \mathbf{W}_{\text{DL}}[n, m] \mathbf{W}_{\text{DL}}^{\text{H}}[n, m] \mathbf{H}_{\text{DL}}[n, m] \right), \quad (11)$$

where  $\mathbf{H}_{\text{DL}}[n, m] = [\mathbf{h}_{\text{DL}}^1[n, m], \dots, \mathbf{h}_{\text{DL}}^U[n, m]]$ . To evaluate the sensing performance, we adopt the MI as sensing metric, which exhibits the information-theoretic limit on how much environmental information can be exploited,

and hence is widely used in the ISAC literature [25, 32]. As seen in (3) and (9), the objective of sensing is to obtain the information of targets included in  $\mathbf{H}_{\text{SEN}}[n, m']$  based on the perceived signal  $\mathbf{y}_{\text{PE}}[n, t, m, m']$  at the TBS. Therefore, the end-to-end sensing MI at the  $n$ -th  $R_{\text{F}}$  is given in (12) at the bottom of the page, where the entries of  $\mathbf{G}[n, m']$  are given by  $(\mathbf{G}[n, m'])_{a,b} = \boldsymbol{\alpha}_{\text{rx}}^{\text{H}}(\theta_a^{\text{rx}}[n], \phi_a^{\text{rx}}[n], m') \boldsymbol{\alpha}_{\text{rx}}(\theta_b^{\text{rx}}[n], \phi_b^{\text{rx}}[n], m')$ ,  $\forall a, b \in \mathcal{J}$ ,  $\boldsymbol{\Omega}_{\text{SEN}}[n, m']$  is a diagonal matrix with the diagonal entries  $(\boldsymbol{\Omega}_{\text{SEN}}[n, m'])_a = \frac{G_{\text{UAV}}^{\text{tx}} G_{\text{UAV}}^{\text{rx}} \lambda_{m'}^2 \sigma_j^{\text{RCS}} |\varpi_{j,m'}|^2}{(4\pi)^3 d_j^4[n]}$ ,  $\forall a \in \mathcal{J}$ , and

$$\Gamma[n, m, m'] = \boldsymbol{\Lambda}_{\text{PE}}^{1/2}[n, m] \mathbf{\Sigma}_{\text{PE}}^{1/2}[n, m] \widetilde{\mathbf{W}}_{\text{SEN}}^{\text{H}}[n, m'] \left( (\xi_{\text{SIC}} \right. \\ \left. \times \text{Tr}(\mathbf{\Sigma}_{\text{SEN}}[n, m']) + N_0) \mathbf{I}_{R_{\text{rx}}} \right) \widetilde{\mathbf{W}}_{\text{SEN}}[n, m'] \mathbf{\Sigma}_{\text{PE}}^{1/2}[n, m] \\ \times \boldsymbol{\Lambda}_{\text{PE}}^{1/2}[n, m] + N_0 \mathbf{I}_J. \quad (13)$$

According to (10) and (12), the optimization problem can be formulated as

$$(P1): \quad \max_{\{\alpha_{n,m}^{\text{x}}, \mathcal{M}_n^{\text{pair}}\}, \{\mathbf{\Sigma}[n, m]\}, \{\mathbf{c}_{\text{UAV}}[n]\}} \min \{R_{\text{CD}}[n], R_{\text{DL}}[n]\}, \quad (14a)$$

$$\text{s.t. } \alpha_{n,m}^{\text{DL}} + \alpha_{n,m}^{\text{SEN}} + \alpha_{n,m}^{\text{PE}} + \alpha_{n,m}^{\text{CD}} \leq 1, \forall n, \forall m \in \mathcal{M}, \quad (14b)$$

$$\alpha_{n,m}^{\text{x}} \in \{0, 1\}, \forall n, \forall m \in \mathcal{M}, \forall \mathbf{x}, \quad (14c)$$

$$\sum_{m \in \mathcal{M}} \alpha_{n,m}^{\text{SEN}} = \sum_{m \in \mathcal{M}_n} \alpha_{n,m}^{\text{PE}} = \frac{M}{4}, \forall n, \quad (14d)$$

$$\sum_{m \in \mathcal{M}} \alpha_{n,m}^{\text{CD}} + \sum_{m \in \mathcal{M}} \alpha_{n,m}^{\text{DL}} = \frac{M}{2}, \forall n, \quad (14e)$$

$$\sum_{m \in \mathcal{M}} R_{\text{DL}}^u[n, m] \geq R_{\text{DL}}^{\text{min}}, \forall n, \forall u \in \mathcal{U}, \quad (14f)$$

$$\sum_{(m, m') \in \mathcal{M}_n^{\text{pair}}} R_{\text{MI}}^j[n, m, m'] \geq R_{\text{MI}}^{\text{min}}, \forall n, \forall j \in \mathcal{J}, \quad (14g)$$

$$\sum_{m \in \mathcal{M}} \alpha_{n,m}^{\text{DL}} \text{Tr}(\mathbf{\Sigma}_{\text{DL}}[n, m]) \\ + \sum_{(m, m') \in \mathcal{M}_n^{\text{pair}}} \left( \alpha_{n,m'}^{\text{SEN}} \text{Tr}(\mathbf{\Sigma}_{\text{SEN}}[n, m']) + \alpha_{n,m}^{\text{PE}} \alpha_{n,m'}^{\text{SEN}} \right. \\ \left. \times \text{Tr}(\mathbf{\Pi}_{\text{SEN}}[n, m'] \mathbf{\Sigma}_{\text{PE}}[n, m]) \right) \leq P_{\text{UAV}}, \forall n, \quad (14h)$$

$$\sum_{m \in \mathcal{M}} \alpha_{n,m}^{\text{CD}} \text{Tr}(\mathbf{\Sigma}_{\text{CD}}[n, m]) \leq P_{\text{TBS}}, \forall n, \quad (14i)$$

$$\|\mathbf{c}_{\text{UAV}}[n] - \mathbf{c}_{\text{UAV}}[n-1]\| \leq V_{\text{max}} N_s T_s, \forall n > 1, \quad (14j)$$

where  $\mathbf{\Pi}_{\text{SEN}}[n, m'] = \mathbf{G}^{\text{H}}[n, m'] \boldsymbol{\Omega}_{\text{SEN}}[n, m'] \mathbf{\Sigma}_{\text{SEN}}[n, m'] \mathbf{G}[n, m'] + \widetilde{\mathbf{W}}_{\text{SEN}}^{\text{H}}[n, m'] \left( (\xi_{\text{SIC}} \text{Tr}(\mathbf{\Sigma}_{\text{SEN}}[n, m']) + N_0) \mathbf{I}_{R_{\text{rx}}} \right) \widetilde{\mathbf{W}}_{\text{SEN}}[n, m']$ , and  $R_{\text{DL}}^u[n, m] = \frac{N_s - 2}{N_s} \log(1 + \alpha_{n,m}^{\text{DL}} \text{SINR}_{\text{DL}}^u[n, m])$  with

$$\text{SINR}_{\text{DL}}^u[n, m] = \frac{p_{\text{DL}}^u[n, m] \Omega_{\text{DL}}^u[n, m]}{\sum_{u'=1, u' \neq u}^U p_{\text{DL}}^{u'}[n, m] \Omega_{\text{DL}}^{u'}[n, m] \left| G_{\text{DL}}^{u', u}[n, m] \right|^2 + N_0}, \quad (15)$$

$$R_{\text{MI}}[n, m, m'] = \frac{N_s - 3}{N_s} \mathcal{I}(\mathbf{y}_{\text{PE}}[n, t, m, m']; \mathbf{H}_{\text{SEN}}[n, m'] | \mathbf{x}_{\text{SEN}}[n, t, m']) = \frac{N_s - 3}{N_s} \log \det \left( \mathbf{I}_J + \alpha_{m', n}^{\text{SEN}} \alpha_{n, m}^{\text{PE}} \boldsymbol{\Gamma}^{-1}[n, m, m'] \right. \\ \left. \times \boldsymbol{\Lambda}_{\text{PE}}^{1/2}[n, m] \mathbf{\Sigma}_{\text{PE}}^{1/2}[n, m] \mathbf{G}[n, m'] \boldsymbol{\Omega}_{\text{SEN}}[n, m'] \mathbf{\Sigma}_{\text{SEN}}[n, m'] \mathbf{G}[n, m'] \mathbf{\Sigma}_{\text{PE}}^{1/2}[n, m] \boldsymbol{\Lambda}_{\text{PE}}^{1/2}[n, m] \right), \quad (12)$$

in which  $\Omega_{\text{DL}}^u[n, m] = \frac{G_{\text{UAV}}^{\text{tx}} G_{\text{UE}}^{\text{rx}} \lambda_n^2 |\varpi_{u,m}|^2}{(4\pi)^2 d_u^2[n]}$  and  $G_{\text{DL}}^{u,u}[n, m] = \alpha_{\text{tx}}^{\text{H}}(\theta_u^{\text{tx}}[n], \phi_u^{\text{tx}}[n], m) \alpha_{\text{tx}}(\theta_u^{\text{tx}}[n], \phi_u^{\text{tx}}[n], m)$ .

The objective function implies that the final end-to-end DL rate is the minimum of the access rate and fronthaul rate. Constraints (14b)-(14e) denote the orthogonality and relative sizes among different subcarrier sets. The user's minimum achievable DL rate requirement at each  $R_{\text{F}}$  is given by (14f). The constraint on the required target estimation accuracy in terms of sensing MI per  $R_{\text{F}}$  is given by (14g), where  $R_{\text{MI}}^{\text{min}}$  is the minimum threshold reflecting the basic target characteristics [25]. The maximum transmission power of the UAV and TBS are constrained by (14h) and (14i), respectively. As the velocity of the UAV is lower than  $V_{\text{max}}$ , the maximum flight distance between two consecutive time slots is constrained in (14j).

*Remark 2.* Different from terrestrial scenarios where on-demand UAV is usually deployed nearby and can carry out transmissions immediately after taking off, the departure point of the UAV in the considered maritime scenario is far away from the destination. Due to the extremely high path loss caused by long distance, the performance of DL communication and especially sensing hardly satisfy the QoS constraints given in (14f) and (14g). Therefore, before handling the optimization problem (P1), it is necessary to first find the initial operating position at which the UAV can simultaneously activate the communication and sensing services toward emergency area. When the UAV arrives at this initial operating position, it can start to work for solving the optimization problem (P1).

#### IV. SOLUTIONS TO TWO SUB-PROBLEMS

As discussed in Remark 2, dealing with the problem (P1) amounts to consecutively solve the two sub-problems: i) Finding a suitable initial operating position  $\mathbf{c}_{\text{UAV}}[1]$  at the first  $R_{\text{F}}$ ; ii) Starting from this initial operating position, optimizing the trajectory and resource allocation to maximize DL rate while guaranteeing sensing QoS.

##### A. First Sub-Problem: Finding Initial Operating Position

We assume that the UAV takes off from the coastal base with the coordinate of  $\mathbf{c}_{\text{UAV}}[0]$ . For the purpose of emergency rescue, the UAV is expected to provide prompt communication and sensing services after receiving the command from the TBS. To this end, the distance between  $\mathbf{c}_{\text{UAV}}[0]$  and  $\mathbf{c}_{\text{UAV}}[1]$  should be as close as possible, but at the same time, the minimum QoS of both communication and sensing must be satisfied at  $\mathbf{c}_{\text{UAV}}[1]$ . Hence, the first sub-problem can be formulated as follows

$$(P2) : \min_{\mathbf{c}_{\text{UAV}}[1]} \|\mathbf{c}_{\text{UAV}}[1] - \mathbf{c}_{\text{UAV}}[0]\|^2, \quad (16a)$$

$$\text{s.t. } R_{\text{CD}}[1] \geq UR_{\text{DL}}^{\text{min}}, \quad (16b)$$

$$(14b) - (14i) \text{ for } n = 1. \quad (16c)$$

The constraint (16b) ensures that the fronthaul link is able to support the basic DL communication QoS. The optimization (P2) is challenging to solve directly owing

to the non-convex constraints (14f)-(14h) and the binary integer constraints (14b)-(14e).

1) *Transform Subcarrier-Related Constraints:* Recall that there are  $M/4$  pairs of  $(m, m') \in \mathcal{M}_n^{\text{pair}}$  with  $m \in \mathcal{M}_n^{\text{PE}}$  and  $m' \in \mathcal{M}_n^{\text{SEN}}$ , where  $m'$  and  $m$  are used by the UAV to transmit probing signals and convey the collected sensing data to the TBS, respectively. As the performance loss of UAV-target link is much larger than that of UAV-TBS link, to find a suitable initial position, intuitively UAV-target links should have the priority to select subcarriers from  $\mathcal{M}^{\text{S}}$  such that the sensing QoS can be efficiently satisfied. Hence, for the first  $R_{\text{F}}$   $n = 1$ ,  $\alpha_{1,m'}^{\text{SEN}}$  can be determined as follows:<sup>1</sup> a.i) Set  $\alpha_{1,m'}^{\text{SEN}} = 0$ ,  $\forall m' \in \mathcal{M}^{\text{S}}$  and  $k = 1$ ; a.ii) Find  $m'_k$  by solving  $m'_k = \arg \max_{m' \in \mathcal{M}^{\text{S}}} \text{Tr}(\mathbf{\Omega}_{\text{SEN}}[1, m'])$ , and update  $\alpha_{1,m'_k}^{\text{SEN}} = 1$ ,  $\mathcal{M}_1^{\text{SEN}} = \mathcal{M}_1^{\text{SEN}} \cup \{m'_k\}$  and  $k = k + 1$ ; a.iii) Repeat step a.ii) until  $|\mathcal{M}_1^{\text{SEN}}| = M/4$ . Then, we have  $\alpha_{1,m}^{\text{PE}} = 1$ ,  $m \in \mathcal{M}_1^{\text{PE}}$ , where  $\mathcal{M}_1^{\text{PE}} = \mathcal{M}^{\text{S}} - \mathcal{M}_1^{\text{SEN}}$ . To maximize the end-to-end sensing MI under greedy principle,  $\mathcal{M}_1^{\text{pair}}$  can be determined as follows: b.i) Set  $\mathcal{M}_1^{\text{pair}} = \emptyset$  and  $k = 1$ ; b.ii) Find  $m_k$  by solving  $m_k = \arg \max_{m \in \mathcal{M}_1^{\text{PE}}} \text{Tr}(\mathbf{\Lambda}_{\text{PE}}[1, m])$ , and update  $\mathcal{M}_1^{\text{pair}} = \mathcal{M}_1^{\text{pair}} \cup \{(m_k, m'_k)\}$  and  $k = k + 1$ ; b.iii) Repeat step b.ii) until  $k = M/4$ . So far,  $\{\alpha_{1,m}^{\text{PE}}, \alpha_{1,m}^{\text{SEN}}, \mathcal{M}_1^{\text{pair}}\}$  have been determined. Then (14b) is reformed as

$$\alpha_{1,m}^{\text{DL}} + \alpha_{1,m}^{\text{CD}} \leq 1, \quad \forall m \in \mathcal{M}^{\text{D}}. \quad (17)$$

The residual binary variables  $\alpha_{1,m}^{\text{DL}}$  and  $\alpha_{1,m}^{\text{CD}}$  are coupled with  $\mathbf{\Sigma}_{\text{DL}}[1, m]$  and  $\mathbf{\Sigma}_{\text{CD}}[1, m]$ , respectively, as shown in (14f), (14h), (14i) and (16b), which makes these constraints non-convex. Basically, there are four possible combinations between the values of DL-related subcarrier indicators and power matrices, which are  $\{(\alpha_{1,m}, \mathbf{\Sigma}[1, m]) | \alpha_{1,m} \in \{0, 1\}, \mathbf{\Sigma}[1, m] \in \{\mathbf{0}, \bar{\mathbf{A}}[1, m]\}\}$ , where  $\bar{\mathbf{A}}[1, m] \succeq \mathbf{0}$  and  $\bar{\mathbf{A}}[1, m] \neq \mathbf{0}$ . However, it can be seen that only  $(0, \mathbf{0})$  and  $(1, \bar{\mathbf{A}}[1, m])$  can be the feasible solutions for the problem (P2). Take  $(\alpha_{1,m}^{\text{DL}}, \mathbf{\Sigma}_{\text{DL}}[1, m])$  as an example. If  $(\alpha_{1,m}^{\text{DL}}, \mathbf{\Sigma}_{\text{DL}}[1, m]) = (0, \bar{\mathbf{A}}[1, m])$ , the power allocated to the  $m$ -th subcarrier have no impact on  $R_{\text{DL}}[1]$ , and these power will be allocated to other subcarriers to maximize  $R_{\text{DL}}[1]$ , leading to  $\bar{\mathbf{A}}[1, m] = \mathbf{0}$  at the end of optimization. If  $(\alpha_{1,m}^{\text{DL}}, \mathbf{\Sigma}_{\text{DL}}[1, m]) = (1, \mathbf{0})$ , the  $m$ -th subcarrier is wasted as no power is allocated to it. Hence, the optimization is prone to assign subcarrier  $m$  to fronthaul link for transmitting coded data from TBS to UAV, as the end-to-end DL rate is the minimum of access and fronthaul rates. Thus, we can remove the binary variables by introducing the auxiliary matrices:

$$\begin{cases} \bar{\mathbf{\Sigma}}_{\text{DL}}[1, m] &= \text{diag}(\bar{p}_{\text{DL}}^1[1, m], \dots, \bar{p}_{\text{DL}}^U[1, m]) \\ &= \alpha_{1,m}^{\text{DL}} \mathbf{\Sigma}_{\text{DL}}[1, m], \\ \bar{\mathbf{\Sigma}}_{\text{CD}}[1, m] &= \text{diag}(\bar{p}_{\text{CD}}^1[1, m], \dots, \bar{p}_{\text{CD}}^U[1, m]) \\ &= \alpha_{1,m}^{\text{CD}} \mathbf{\Sigma}_{\text{CD}}[1, m]. \end{cases} \quad (18)$$

<sup>1</sup>Although the proposed method is suboptimal in terms of performance, its low complexity is more practical for the UAV scenario. Our future work will study the deep reinforcement learning assisted subcarrier allocation among fronthaul and access links to take both performance and complexity into account.

$$\Upsilon(\bar{\Sigma}_X[1, m]) = 1 - e^{-\frac{\text{Tr}(\bar{\Sigma}_X[1, m])}{\rho_X^{(k)}}} \stackrel{(a)}{\leq} 1 - e^{-\frac{\text{Tr}(\bar{\Sigma}_X^{(k)}[1, m])}{\rho_X^{(k)}}} + \frac{1}{\rho_X^{(k)}} e^{-\frac{\text{Tr}(\bar{\Sigma}_X^{(k)}[1, m])}{\rho_X^{(k)}}} \text{Tr}(\bar{\Sigma}_X[1, m] - \bar{\Sigma}_X^{(k)}[1, m]) \triangleq \tilde{\Upsilon}(\bar{\Sigma}_X[1, m]), \quad (20)$$

$$S_{\text{MI}}^j[1, m, m'] = \frac{\eta_{\text{PE}}^j[1, m] p_{\text{PE}}^j[1, m]}{Z_{\text{TU}}[1]} \left( \sum_{j'=1}^J p_{\text{SEN}}^{j'}[1, m'] \left( \left| (\mathbf{G}[1, m'])_{j, j'} \right|^2 \frac{(\bar{\Omega}_{\text{SEN}}[1, m'])_{j'}}{Z_{j'}^2[1]} + \xi_{\text{SIC}} \right) + N_0 \right) + N_0, \quad (25)$$

$$N_{\text{MI}}^j[1, m, m'] = \frac{\eta_{\text{PE}}^j[1, m] p_{\text{PE}}^j[1, m]}{Z_{\text{TU}}[1]} \left( \sum_{j'=1, j' \neq j}^J p_{\text{SEN}}^{j'}[1, m'] \left| (\mathbf{G}[1, m'])_{j, j'} \right|^2 \frac{(\bar{\Omega}_{\text{SEN}}[1, m'])_{j'}}{Z_{j'}^2[1]} + \sum_{j'=1}^J p_{\text{SEN}}^{j'}[1, m'] \xi_{\text{SIC}} + N_0 \right) + N_0, \quad (26)$$

Then (17) is converted into

$$\|\text{Tr}(\bar{\Sigma}_{\text{DL}}[1, m])\|_0 + \|\text{Tr}(\bar{\Sigma}_{\text{CD}}[1, m])\|_0 \leq 1, \forall m \in \mathcal{M}^D. \quad (19)$$

A smooth function is adopted to approximate the two non-convex  $\mathcal{L}_0$ -norm functions in (19), which is given in (20) at the top of the page, where  $X \in \{\text{DL}, \text{CD}\}$ , (a) is derived by using the first-order Taylor expansion, and  $\rho_X^{(k)}$  is an iterative smoothing parameter.

2) *Transform Communication-Related Constraints:*

Based on (18),  $R_{\text{DL}}[1]$  and  $R_{\text{CD}}[1]$  are reformulated as

$$\begin{cases} R_{\text{DL}}[1] = \sum_{u=1}^U \frac{N_s - 2}{N_s} \underbrace{\sum_{m \in \mathcal{M}^D} \log \left( 1 + \frac{S_{\text{DL}}^u[1, m]}{N_{\text{DL}}^u[1, m]} \right)}_{R_{\text{DL}}^u[1]}, \\ R_{\text{CD}}[1] = \sum_{u=1}^U \frac{N_s - 1}{N_s} \sum_{m \in \mathcal{M}^D} \log \left( 1 + \frac{S_{\text{CD}}^u[1, m]}{N_{\text{CD}}^u[1, m]} \right), \end{cases} \quad (21)$$

where  $S_{\text{DL}}^u[1, m] = \bar{p}_{\text{DL}}^u[1, m] \bar{\Omega}_{\text{DL}}^u[1, m] |G_{\text{DL}}^{u, u}[1, m]|^2$ ,  $S_{\text{CD}}^u[1, m] = \eta_{\text{CD}}^u[1, m] p_{\text{CD}}^u[1, m]$ ,  $N_{\text{DL}}^u[1, m] = \sum_{u'=1, u' \neq u}^U \bar{p}_{\text{DL}}^{u'}[1, m] \bar{\Omega}_{\text{DL}}^{u'}[1, m] |G_{\text{DL}}^{u, u'}[1, m]|^2 + N_0 Z_u[1]$  and  $N_{\text{CD}}^u[1, m] = N_0 Z_{\text{TU}}[1]$  with  $Z_u[1] = d_u^2[1] = (x_{\text{UAV}}[1] - x_u)^2 + (y_{\text{UAV}}[1] - y_u)^2 + (z_{\text{UAV}} - z_u)^2$ ,  $Z_{\text{TU}}[1] = d_{\text{TU}}^2[1] = (x_{\text{UAV}}[1] - x_{\text{TBS}})^2 + (y_{\text{UAV}}[1] - y_{\text{TBS}})^2 + (z_{\text{UAV}} - z_{\text{TBS}})^2$  and  $\bar{\Omega}_{\text{DL}}^u[1, m] = \bar{\Omega}_{\text{DL}}^u[1, m] / d_u^2[1]$ . It can be seen that in (21),  $R_{\text{DL}}^u[1]$  is a sum-of-functions-of-ratio problem and  $S_{\text{DL}}^u[1, m] / N_{\text{DL}}^u[1, m]$  satisfies the form of concave/convex. Hence, we can convexify the constraint (14f) in an iterative manner with the aid of quadratic transform [33], which can be expressed as

$$\frac{N_s - 2}{N_s} \sum_{m \in \mathcal{M}^D} \log \left( 1 + 2v_{\text{DL}}^{u(k)}[1, m] \sqrt{S_{\text{DL}}^{u(k+1)}[1, m]} - (v_{\text{DL}}^{u(k)}[1, m])^2 N_{\text{DL}}^{u(k+1)}[1, m] \right) \triangleq \tilde{R}_{\text{DL}}^u[1] \geq R_{\text{DL}}^{\text{min}} \quad (22)$$

with  $v_{\text{DL}}^{u(k)}[1, m] = \sqrt{S_{\text{DL}}^{u(k)}[1, m] / N_{\text{DL}}^{u(k)}[1, m]}$ ,  $\forall u$ .  $\tilde{R}_{\text{DL}}^u[1]$  is concave when  $\{v_{\text{DL}}^{u(k)}[1, m]\}$  is fixed, and the constraint (22) can be iteratively approximated as a convex one. Similarly, the constraint (16b) can be convexified as

$$UR_{\text{DL}}^{\text{min}} - \tilde{R}_{\text{CD}}[1] \leq 0, \quad (23)$$

where  $\tilde{R}_{\text{CD}}[1] \triangleq \sum_{m \in \mathcal{M}^D} \sum_{u=1}^U \frac{N_s - 1}{N_s} \log \left( 1 + 2v_{\text{CD}}^{u(k)}[1, m] \sqrt{S_{\text{CD}}^{u(k+1)}[1, m]} - (v_{\text{CD}}^{u(k)}[1, m])^2 N_{\text{CD}}^{u(k+1)}[1, m] \right)$

with  $v_{\text{CD}}^{u(k)}[1, m] = \sqrt{S_{\text{CD}}^{u(k)}[1, m] / N_{\text{CD}}^{u(k)}[1, m]}$ ,  $\forall u$ .

3) *Transform Sensing-Related Constraints:* In order to transform the MI-related constraints (14g) and (14h) into convex ones, we first present the MI of  $j$ -th target over  $(m, m')$  pair, which is given by

$$R_{\text{MI}}^j[1, m, m'] = \frac{N_s - 3}{N_s} \left( \log \left( S_{\text{MI}}^j[1, m, m'] \right) - \log \left( N_{\text{MI}}^j[1, m, m'] \right) \right), \quad (24)$$

where  $S_{\text{MI}}^j[1, m, m']$  and  $N_{\text{MI}}^j[1, m, m']$  are given in (25) and (26) at the top of the page, with the diagonal entry  $(\bar{\Omega}_{\text{SEN}}[1, m'])_{j'} = (\bar{\Omega}_{\text{SEN}}[1, m'])_{j'} / d_j^4[n]$ ,  $Z_{j'}[1] = d_{j'}^2[1] = (x_{\text{UAV}}[1] - x_{j'})^2 + (y_{\text{UAV}}[1] - y_{j'})^2 + (z_{\text{UAV}} - z_{j'})^2$  and  $Z_{\text{TU}}[1] = d_{\text{TU}}^2[1] = (x_{\text{UAV}}[1] - x_{\text{TBS}})^2 + (y_{\text{UAV}}[1] - y_{\text{TBS}})^2 + (z_{\text{UAV}} - z_{\text{TBS}})^2$ . With the aid of the first-order Taylor expansion and successive convex approximation (SCA),  $\log(S_{\text{MI}}^j[1, m, m'])$  and  $\log(N_{\text{MI}}^j[1, m, m'])$  can be iteratively approximated in a linearized way. The detailed derivation is given in Appendix A. Thus the constraint (14g) is reformulated as

$$\sum_{(m, m') \in \mathcal{M}_1^{\text{pair}}} \sum_{j=1}^J \left( \tilde{N}_{\text{MI}}^j[1, m, m'] - \tilde{S}_{\text{MI}}^j[1, m, m'] \right) + \frac{N_s R_{\text{MI}}^{\text{min}}}{N_s - 3} \leq 0, \quad (27)$$

which is convex. In addition, the MI-related constraint (14h) can be rewritten as

$$\sum_{m \in \mathcal{M}^D} \text{Tr}(\bar{\Sigma}_{\text{DL}}[1, m]) + \sum_{(m, m') \in \mathcal{M}_1^{\text{pair}}} \left( \text{Tr}(\bar{\Sigma}_{\text{SEN}}[1, m']) + \sum_{j=1}^J \tilde{P}_{\text{MI}}^j[1, m, m'] \right) - P_{\text{UAV}} \leq 0, \quad (28)$$

where  $\tilde{P}_{\text{MI}}^j[1, m, m']$  is the linear approximation of  $P_{\text{MI}}^j[1, m, m']$ , which is given by

$$P_{\text{MI}}^j[1, m, m'] = p_{\text{PE}}^j[1, m] \left( \sum_{j'=1}^J p_{\text{SEN}}^{j'}[1, m'] \right)$$

$$\times \left( \left| \left( \mathbf{G}[1, m'] \right)_{j,j'} \right|^2 \frac{(\bar{\Omega}_{\text{SEN}}[1, m'])_{j'}}{Z_j^2[1]} + \xi_{\text{SIC}} \right) + N_0. \quad (29)$$

Based on the above transformation, the problem (P2) can be rewritten as

$$(P2.1): \min_{\mathbf{c}_{\text{UAV}}[1]} \|\mathbf{c}_{\text{UAV}}[1] - \mathbf{c}_{\text{UAV}}[0]\|^2, \quad (30a)$$

$$\text{s.t. } \tilde{\Upsilon}(\bar{\Sigma}_{\text{DL}}[1, m]) + \tilde{\Upsilon}(\bar{\Sigma}_{\text{CD}}[1, m]) \leq 1, \forall m \in \mathcal{M}^{\text{D}}, \quad (30b)$$

$$\sum_{m \in \mathcal{M}^{\text{D}}} \text{Tr}(\bar{\Sigma}_{\text{CD}}[1, m]) \leq P_{\text{TBS}}, \quad (30c)$$

$$\left| p_{\text{PE}}^{j(k)}[1, m] - p_{\text{PE}}^{j(k-1)}[1, m] \right| \leq \vartheta^{(k)} \mu_{\text{p}}, \forall j \in \mathcal{J}, \\ \forall m \in \mathcal{M}_1^{\text{PE}}, \quad (30d)$$

$$\left| p_{\text{SEN}}^{j'(k)}[1, m'] - p_{\text{SEN}}^{j'(k-1)}[1, m'] \right| \leq \vartheta^{(k)} \mu_{\text{s}}, \forall j' \in \mathcal{J}, \\ \forall m' \in \mathcal{M}_1^{\text{SEN}}, \quad (30e)$$

$$\left| x_{\text{UAV}}^{(k)}[1] - x_{\text{UAV}}^{(k-1)}[1] \right| \leq \vartheta^{(k)} \mu_{\text{x}}, \quad (30f)$$

$$\left| y_{\text{UAV}}^{(k)}[1] - y_{\text{UAV}}^{(k-1)}[1] \right| \leq \vartheta^{(k)} \mu_{\text{y}}, \quad (30g)$$

$$(22), (23), (27), (28), \quad (30h)$$

where  $0 < \vartheta^{(k)} \leq 1$  is a decreasing factor. As the linear approximation based on first-order Taylor expansion is used in (27) and (28), we impose the constraints (30d)-(30g) to guarantee the accuracy of approximation.

4) *Algorithm Implementation:* In (P2.1), the involved QoS constraints are carried out in an iterative manner. To implement iterative optimization, it is crucial to find the initial iteration values of power allocation, and the UAV position, i.e.,  $x_{\text{UAV}}^{(0)}[1]$  and  $y_{\text{UAV}}^{(0)}[1]$ , within the feasible region, since both communication and sensing performance depend heavily on the lengths of fronthaul and access links. Hence, during the algorithm implementation, we first initialize  $\{\bar{p}_{\text{DL}}^{u(0)}[1, m], \bar{p}_{\text{CD}}^{u(0)}[1, m]\}$  and  $\{p_{\text{SEN}}^{j'(0)}[1, m']\}$

through equal power allocation. Since  $p_{\text{PE}}^j[1, m]$  is actually the power coefficient rather than the real power allocated to each target, which is highly related to the UAV position as implied from (29),  $\{p_{\text{PE}}^{j(0)}[1, m]\}$  cannot be easily obtained by power equalization. Thus we derive them by solving the following optimization problem:

$$(P2.2): \max_{\{p_{\text{PE}}^{j(0)}[1, m]\}} \chi, \quad (31a)$$

$$\text{s.t. } \sum_{(m, m') \in \mathcal{M}_1^{\text{pair}}} \eta_{\text{PE}}^j[1, m] P_{\text{MI}}^{j(0)}[1, m, m'] \geq \chi, \forall j \in \mathcal{J}, \quad (31b)$$

$$\sum_{m \in \mathcal{M}^{\text{D}}} \text{Tr}(\bar{\Sigma}_{\text{DL}}^{(0)}[1, m]) + \sum_{(m, m') \in \mathcal{M}_1^{\text{pair}}} \left( \text{Tr}(\bar{\Sigma}_{\text{SEN}}^{(0)}[1, m']) \right. \\ \left. + \sum_{j=1}^J P_{\text{MI}}^{j(0)}[1, m, m'] \right) - P_{\text{UAV}} \leq 0, \quad (31c)$$

where the constraint (31b) ensures that the initialization of  $p_{\text{PE}}^{j(0)}[1, m]$  maximizes the performance of sensing fronthaul link under fairness consideration.

*Remark 3.* Using the fixed searching step, we can find the

Output :  $\mathbf{c}_{\text{UAV}}[1]$ .

```

---

feasibly initial iteration value of the UAV position that satisfies all the constraints. The problem (P2.1) aims to minimize the distance between the initial operating point and the take-off point, and the optimal solution may be several kilometer long, which may cause the problem that the first-order Taylor expansion based SCA method is susceptible to get stuck in multiple inflection points during the optimization process. To address this issue, we propose an enhanced local approximation (ELA) method using double-layer iteration to handle the optimization, and the detailed implementation is summarized in Algorithm 1.

### B. Second Sub-Problem: Optimization From Initial Operating Position Toward Emergency Area

Once the UAV arrives at the initial operating position, it starts to simultaneously carry out communication and sensing tasks with the objective of maximizing the end-to-end DL rate subject to the required sensing QoS, which leads to the second sub-problem expressed as

$$(P3) : \max_{\{\alpha_{n,m}, \mathcal{M}_n^{\text{pair}}\}, \{\Sigma[n,m], \mathbf{\Sigma}[n,m]\}, \{c_{\text{UAV}}[n]\}} \psi, \quad (32a)$$

$$\text{s.t. } R_{\text{DL}}[n] \geq \psi, \forall n > 1, \quad (32b)$$

$$R_{\text{CD}}[n] \geq \psi, \forall n > 1, \quad (32c)$$

$$\sum_{m \in \mathcal{M}^{\text{S}}} \alpha_{n,m}^{\text{SEN}} = \sum_{m \in \mathcal{M}_n^{\text{S}}} \alpha_{n,m}^{\text{PE}} = \frac{M}{4}, \forall n > 1, \quad (32d)$$

$$(14j), (27), (28), (30b) - (30g). \quad (32e)$$

(32b) and (32c) can be convexified by linearizing  $R_{\text{DL}}[n]$  and  $R_{\text{CD}}[n]$ , respectively, following the same method as used in (22) and (23).

Next, we have to deal with the constraint (32d), since the MI-related subcarrier allocation in (P3) is totally different from that in (P2). Specifically, after the UAV passing the initial operating position, its relative distances to the TBS and targets are continuously changing, and it is hard to say whether the UAV-target link or UAV-TBS link should have priority in subcarrier allocation. We adopt the following dynamic allocation method for MI-related subcarriers. After the UAV passing the initial operating position, the UAV-target sensing link has the priority to select subcarriers. Following the same method proposed in Subsection IV-A1, we obtain  $\mathcal{M}_2^{\text{PE}}$  and  $\mathcal{M}_2^{\text{SEN}}$ . After solving (P3), if the sensing performance improves at the second  $R_{\text{F}}$ , i.e.,  $\sum_{(m,m') \in \mathcal{M}_2^{\text{pair}}} R_{\text{MI}}[2, m, m'] - \sum_{(m,m') \in \mathcal{M}_1^{\text{pair}}} R_{\text{MI}}[1, m, m'] \geq 0$ , the same principle is applied at the third  $R_{\text{F}}$  to obtain  $\mathcal{M}_3^{\text{PE}}$  and  $\mathcal{M}_3^{\text{SEN}}$ . Otherwise, at the third  $R_{\text{F}}$ , the two sub-carrier sets have to be fine-tuned as follows. First, find  $m'_i = \arg \max_{m' \in \mathcal{M}_3^{\text{SEN}}} \text{Tr}(\mathbf{\Lambda}_{\text{PE}}[3, m'])$  and  $m_j = \arg \min_{m \in \mathcal{M}_3^{\text{PE}}} \text{Tr}(\mathbf{\Lambda}_{\text{PE}}[3, m])$ . Then, implement  $\mathcal{M}_3^{\text{SEN}} = (\mathcal{M}_3^{\text{SEN}} - \{m'_i\}) \cup \{m_j\}$  and  $\mathcal{M}_3^{\text{PE}} = (\mathcal{M}_3^{\text{PE}} - \{m_j\}) \cup \{m'_i\}$ . In addition, the pairing between the subcarriers within  $\mathcal{M}_3^{\text{SEN}}$  and  $\mathcal{M}_3^{\text{PE}}$  are updated. The process is repeated for  $n > 2$  until the end of mission period.

## V. SIMULATION AND RESULT ANALYSIS

We consider a coastal emergency scenario centered at  $(10^4, 10^4, 0)$  m with a radius of 100 m, where  $U = 8$  ships and  $J = 4$  potential targets are uniformly distributed. The TBS employs two  $(8 \times 8)$  UPAs for transmitting and receiving, respectively, and it is situated at the coordinate of  $(0, 0, 10)$  m. The UAV equips two  $(6 \times 6)$  UPAs as transceiver. When receiving the command, it takes off from the coordinate of  $(10, 0, 200)$  m and is headed to the emergency area, while its flying height is kept at 200 m. Once arriving at the initial operating position, the UAV commences the communication and sensing works lasting

TABLE I: Default simulation system parameters

Parameters	Values
TBS and UAV power budget ( $P_{\text{TBS}}, P_{\text{UAV}}$ )	(34, 30) dBm
TBS's transmit and receive antenna gains	(30, 26) dBi
UAV's transmit and receive antenna gains	(24, 20) dBi
User's receive antenna gain ( $G_{\text{UE}}^{\text{rx}}$ )	2 dBi
Noise power spectrum density ( $N_0$ )	-107 dBm
UAV maximum speed ( $V_{\text{max}}$ )	30 m/s
Rician factor ( $K_{\text{TU}}$ )	30
RCS ( $\sigma_j^{\text{RCS}}, \forall j$ )	100 m <sup>2</sup>
Central frequency and bandwidth	5 GHz, 10 MHz
Number of subcarriers ( $M$ )	32
Azimuth AoD/AoA ( $\phi$ )	$\phi \sim \mathcal{U}(-\pi, \pi)$
Elevation AoD/AoA ( $\theta$ )	$\theta \sim \mathcal{U}(-\frac{\pi}{2}, \frac{\pi}{2})$
Minimum communication QoS ( $R_{\text{DL}}^{\text{min}}$ )	10 bit/s/Hz
Minimum sensing QoS ( $R_{\text{MI}}^{\text{min}}$ )	1 bit/s/Hz

for  $T = 500$  s. The number of  $R_{\text{F}}$ s within the mission period is  $N_{\text{t}} = 500$  and the number of time slots within one  $R_{\text{F}}$  is  $N_{\text{s}} = 10$ . Other default system parameters are listed in Table I.

### A. Convergence Performance of Two Sub-problems

Given a random network realization which has the distribution of users and targets depicted in Fig. 3(b), Algorithm 1 is applied to find the UAV's initial operating position, and the optimization process is shown in Fig. 3(a). Specifically, based on steps 6-16 of Algorithm 1, the initial iteration value of the UAV position at  $(9900, 9900, 200)$  m is determined. By applying the ELA method with a dynamically decreasing factor  $\vartheta$ , the distance between the TBS and UAV is minimized until convergence. This initial operating position is the closest point from the TBS that also meets the required CAS QoS at the first  $R_{\text{F}}$ . Next after solving the second sub-problem, the overall optimal UAV trajectory is plotted in Fig. 3(b), where for concise presentation, we uniformly sample 20 points

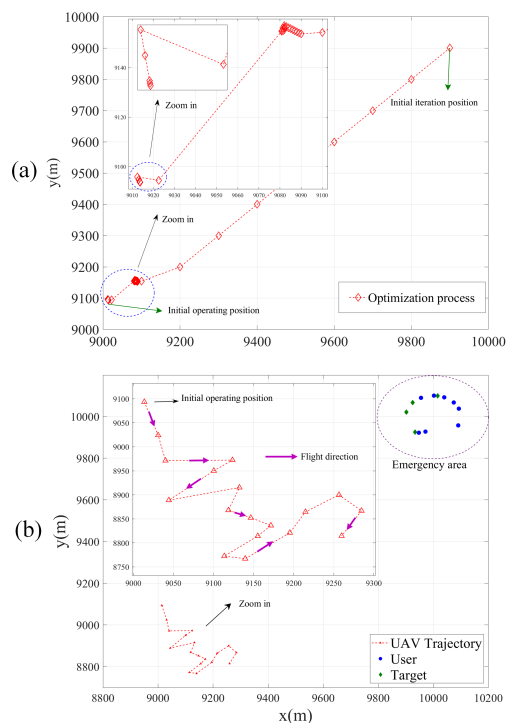

Fig. 3: (a) The optimization process of the first sub-problem, and (b) UAV's optimal trajectory during mission period, for a random network realization.

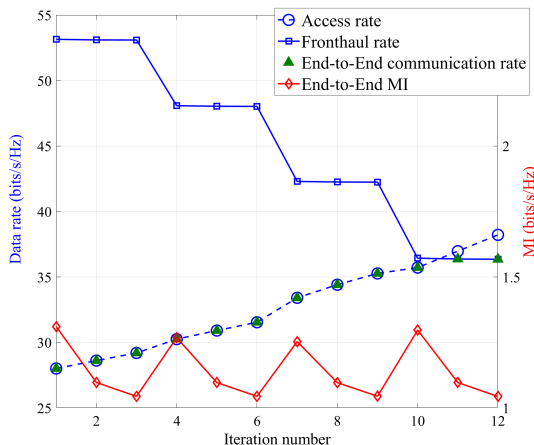

Fig. 4: Convergence behavior of the second sub-problem at a random radio frame.

starting from the initial operating position during the whole mission period. It can be seen from Fig. 3(b) that after the initial operating position, the UAV continuously adjusts the direction and the distance among the TBS and emergency area by considering the effects of fronthaul links, to maximize the end-to-end communication rate while maintaining the required sensing performance.

The optimization process of the second sub-problem at one  $R_F$  is plotted in Fig. 4. It can be seen that at the beginning of the iteration process, the access rate is much larger than the fronthaul rate, owing to the fact that the TBS has a higher power budget and the UAV is still far away from the interested area. As the iteration number increases, the UAV moves closer to users and assigns more subcarriers and power to the access link, which enables the end-to-end communication rate to increase until convergence. Although the MI fluctuates during the iteration process, it is restricted in the feasible region such that the sensing performance is guaranteed.

### B. Performance of Proposed Scheme

We further evaluate the performance of the proposed UAV-ISAC maritime emergency network. To obtain the reliable simulation results, the cumulative distribution function (CDF) performance over thousands of  $R_F$ s are evaluated under various network realizations. Fig. 5(a) depicts the network performance under two different sets of UAV and TBS power budgets. When the power budget increases, the TBS and UAV can assign more power to transmit coded data and DL data via fronthaul and access links, respectively, which lead to higher end-to-end communication rate. Specifically, an increased of 4 dBm power at both the UAV and TBS results in an increased 3 bits/s/Hz at 90% likely rate. By contrast, increasing the power budget imposes negative effect on the end-to-end MI performance. The reason is because in comparison with sending the sensed information back to the TBS over fronthaul link, the sensing over access links is heavily dependent on the link length, as shown in (12). Therefore, when the power budget is reduced, the UAV is prone to be closer to targets so as to guarantee the required sensing QoS, which leads to an increased end-to-end MI.

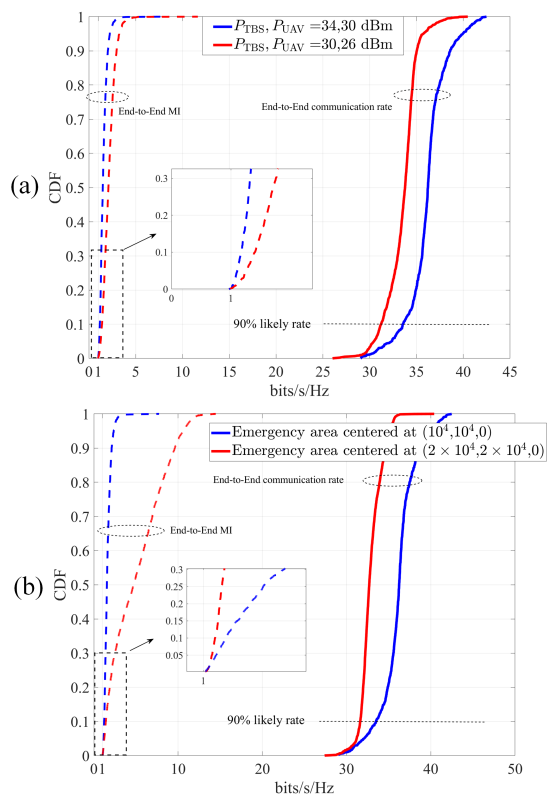

Fig. 5: CDF versus end-to-end communication rate and MI in terms of (a) power budgets and (b) emergency area locations.

Fig. 5(b) studies the impact of emergency area location on the network performance. As expected, the farther the emergency area situates, the smaller the end-to-end communication rate is. When the emergency area is farther away from the coast, the UAV takes the sensing s priority over the access link and therefore tends to fly closer to the targets. To meet the sensing QoS constraint, the UAV may allocate more power to sensing subcarriers, resulting in an increase in the end-to-end MI.

Next we compare our UAV-ISAC scheme with the following four benchmarks in maritime emergency networks.

- **Proposed scheme with random subcarrier allocation** (Proposed Scheme with RanSub): The subcarrier assignment within  $\mathcal{M}^D$  and  $\mathcal{M}^S$  is pre-defined with random selection before the optimization of UAV trajectory and power allocation.
- **TDMA-UAV-ISAC**: The application of TDMA in suppressing the interference between communication and sensing links is widely used in UAV-ISAC, e.g., [17], [19]. To be compatible with the proposed integrated fronthaul-access networks, the  $R_F$  structure of TDMA-UAV-ISAC is designed as in Fig. 6. The guard period is essential to avoid the intra-frame interference in TDD-like systems, which accounts for 1 time slot within each  $R_F$ .

Fig. 6: Radio frame structure of TDMA-UAV-ISAC.

Fig. 7: Network performance comparison for different schemes.

- **Straight-Line Flying (S-Line Flying):** Once the UAV arrives at the initial operating position, it flies along the line between the initial operating position and the center of emergency area. As the trajectory is fixed, the UAV may not meet the sensing or communication QoS requirement at some positions, in which case the UAV is temporarily out of service.
- **No Sensing-QoS Constraint (No Sens-QoS):** The UAV carries out DL communication immediately after taking off from the position (10,0,200) m, and the sensing QoS constraint is neglected during flying.

The performance comparison is presented in Fig. 7. No Sens-QoS scheme achieves the highest end-to-end communication rate but it may not meet the sensing requirement, since the UAV leverages all the resource to implement DL-related transmission over fronthaul and access links. Our proposed UAV-ISAC achieves 5 bits/s/Hz more than TDD-UAV-ISAC scheme at 90% likely rate. It can be attributed to that with the aid of MDD operation and its flexibility in subcarrier allocation, the UAV can simultaneously implement fronthaul and access transmissions at no expense of guard period. The effectiveness of the resource allocation optimization in the proposed scheme is evident as it significantly outperforms Proposed Scheme with RanSub. Without optimizing the UAV’s trajectory, S-Line Flying scheme attains the lowest end-to-end communication rate.

## VI. CONCLUSIONS

This paper has investigated the UAV-enabled ISAC technique in maritime emergency networks. Considering that the real-time DL communications and target sensing require the support of robust wireless fronthaul, we have proposed an MDD-based joint fronthaul-access scheme, where the TBS and UAV exchange the coded DL data and perceived information via fronthaul link, and the UAV transmits ISAC signals via access links. To maximize the end-to-end data rate while guaranteeing the required sensing QoS, we have designed an optimization problem to jointly optimize UAV trajectory, subcarrier and power allocation, which is divided into two stages for practical solution, i.e., finding the UAV’s initial operating position

and optimizing the trajectory and resource allocation in mission period. The SCA and ELA methods have been applied to address the challenging optimization problem. Numerical results have validated that our proposed scheme is capable of balancing the performance between fronthaul and access links such that the communication and sensing services can be properly carried out during UAV’s mission. The advantages of our proposed UAV-ISAC scheme over benchmark schemes have also been demonstrated.

## APPENDIX

### A. Linear Approximation of MI-Related Formulation

For concise expression, the indices of  $R_{Fs}$  and subcarriers are temporarily removed, and notations of PE, SEN, UAV and TBS are simplified as P, S, U and T, respectively. Applying SCA,  $\log(S_{MI}^j)$  in (24) can be approximated as (33) at the top of the next page, where  $\mathcal{Q}_{MI}^{(k)} = (p_P^{j(k)}, p_S^{j(k)}, x_U^{(k)}, y_U^{(k)})$ , while  $\frac{\partial S_{MI}^j}{\partial p_P^j}$ ,  $\frac{\partial S_{MI}^j}{\partial p_S^j}$ ,  $\frac{\partial S_{MI}^j}{\partial x_U}$  and  $\frac{\partial S_{MI}^j}{\partial y_U}$  are given in (34). Similarly,  $\log(N_{NI}^j)$  in (24) can be approximated as (35), where  $\mathcal{Q}_{MI}^{(k)} = (p_P^{j(k)}, p_S^{j(k)}, x_U^{(k)}, y_U^{(k)})$ , while  $\frac{\partial N_{MI}^j}{\partial p_P^j}$ ,  $\frac{\partial N_{MI}^j}{\partial p_S^j}$ ,  $\frac{\partial N_{MI}^j}{\partial x_U}$  and  $\frac{\partial N_{MI}^j}{\partial y_U}$  are given in (36).
