A NOTE ABOUT DUAL REPRESENTATIONS OF GROUP ACTIONS ON LIPSCHITZ-FREE SPACES

MICHAEL MEGRELISHVILI

ABSTRACT. Let $\mathcal{F}(M)$ be the Lipschitz-free space of a pointed metric space M. For every isometric continuous group action of G we have an induced continuous dual action on the weak-star compact unit ball $B_{\mathcal{F}(M)^*}$ of the dual space $\text{Lip}_0(M) =$ $\mathfrak{F}(M)^*$. We pose the question when a given abstract continuous action of G on a topological space X can be represented through a G-subspace of $B_{\mathcal{F}(M)^*}$. One of such natural examples is the so-called metric compactification (of isometric Gspaces) for a pointed metric space. As well as the *Gromov G-compactification* of a bounded metric G-space. Note that there are sufficiently many representations of compact G-spaces on Lipschitz-free spaces.

CONTENTS

1. Introduction

The Lipschitz-free space $\mathcal{F}(M)$ is a Banach space canonically defined for every pointed metric space M which captures several metric properties of M . The theory of Lipschitz-free spaces is a rapidly growing important direction. See, for example, [\[5,](#page-7-0) [1,](#page-6-1) [13\]](#page-7-1) and references therein. Alternative terminology is the free Banach space of M as in a work by V. Pestov [\[11\]](#page-7-2).

In the present note we propose to study dual representations of abstract continuous group actions on Banach spaces $\mathcal{F}(M)$.

First we give necessary definitions. To every Banach space $(V, || \cdot ||)$ one may associate several important structures. Among others: the topological group $Is(V)$ of all linear onto isometries (in its strong operator topology), its canonical dual action on the weak-star compact unit ball B_{V^*} of the dual Banach space V^* . One of the natural ideas is to give a kind of linearization of abstract continuous actions $G \times X \to X$ of a topological group G on a topological space (we say, a $G\text{-}space$) through the dual action on some B_{V^*} .

Key words and phrases. Arens–Eells embedding, Lipschitz-free space, group representation, Gromov compactification.

Definition 1.1. [\[8,](#page-7-3) [3,](#page-7-4) [4\]](#page-7-5) Let X be a G-space. A representation of (G, X) on a Banach space V is a pair

$$
h \colon G \to \text{Is}(V), \quad \alpha \colon X \to V^*
$$

where $h: G \to \text{Is}(V)$ is a continuous homomorphism and $\alpha: X \to V^*$ is a weak^{*} continuous bounded (e.g., $\alpha(X) \subset B_{V^*}$) G-mapping with respect to the dual action

$$
G \times V^* \to V^*, \ (g\varphi)(v) := \varphi(g^{-1}v).
$$

$$
G \times X \longrightarrow X
$$

$$
\downarrow \qquad \qquad \downarrow \alpha \qquad \qquad \downarrow \alpha
$$

$$
\downarrow \qquad \qquad \downarrow \alpha \qquad \qquad \downarrow \alpha
$$

Proper representation will mean that α is a topological embedding. Note that when X is compact then every weak-star continuous $\alpha: X \to V^*$ is necessarily bounded.

 $Is(V) \times V^* \longrightarrow V^*$

This definition brings some new tools studying abstract dynamical G-systems using the geometry of Banach spaces. For some applications and more information we refer to [\[8,](#page-7-3) [4\]](#page-7-5).

Our aim in the present note is to propose linearizations of actions (in the sense of Definition [1.1\)](#page-1-1) but just on the Lipschitz-free space $V := \mathcal{F}(M)$. See Definition [3.2](#page-3-0) as a special case of Definition [1.1.](#page-1-1) Theorem [3.8](#page-5-0) provides a kind of such linearization for the so-called metric compactification (of isometric G-spaces) for a pointed metric space. As well as the $Gromov G$ -compactification of a bounded metric G -space.

Note that (see Remark [3.4\)](#page-3-1) there are sufficiently many representations of compact G-spaces on the Lipschitz-free spaces $\mathcal{F}(M)$. Below we give a necessary background and pose some general questions [\(3.3,](#page-3-2) [3.5,](#page-3-3) [3.6\)](#page-3-4).

Acknowledgment. I would like to thank the organizers and participants of the First Conference on Lipschitz-Free Spaces (Besancon, September 2023) for their inspiration and stimulating discussions. A part of the present article's ideas was presented on this conference.

2. Lipschitz-free spaces

Here we recall shortly well known facts about Lipschitz-free spaces. Let M be a nonempty set. A *molecule* of M is a formal finite sum

$$
m = \sum_{i=1}^{n} c_i (x_i - y_i),
$$

where $x_i, y_i \in M, c_i \in \mathbb{R}, n \in \mathbb{N}$. It can be identified with a function $m \colon M \to \mathbb{R}$ having a finite support such that $\sum_{x \in M} m(x) = 0$. The set Mol(M) of all molecules is a vector space over R. Now, let \overline{d} be a pseudometric on M. Define

$$
||m||_d := \inf \{ \sum_{i=1}^n |c_i| d(x_i, y_i) : m = \sum_{i=1}^n c_i (x_i - y_i) \}.
$$

This is a seminorm on Mol(M). It is well known (and not hard to show) that $|| \cdot ||_d$ is a norm if and only if d is a metric. In this case $(Mol(M), || \cdot ||_d)$ is said to be the Arens-Eells normed space of (M, d) . Mostly we write simply Mol (M) and $|| \cdot ||$.

Remark 2.1. Note that this norm sometimes is called Kantorovich-Rubinstein norm and it plays a major role in a classical branch of the optimization theory. Namely, in transportation problems.

Denote by $\mathcal{F}(M)$ the completion of $(Mol(M), || \cdot ||)$. This Banach space is said to be the *Lipschitz-free space* of (M, d) .

Let $(M, d, 0)$ be a *pointed* metric space with a distinguished point $0 \in M$. For every $x \in M$ define the molecule $\chi_x := x - \mathbf{0}$. The set $\{\chi_x : x \in X\}$ is a Hamel base of the vector space $Mol(M, d)$. Define the following natural injection

$$
\chi \colon M \to \text{Mol}(M, d), \ x \mapsto \chi_x.
$$

Clearly, χ_0 is the zero element **0** of $\mathcal{F}(M)$.

Now recall the description of the dual Banach space $\mathcal{F}(M)^*$ of $\mathcal{F}(M)$ (equivalently, the dual of the normed space $Mol(M, d)$. For every functional $F: \mathcal{F}(M) \to \mathbb{R}$ we have an induced function $f: M \to \mathbb{R}$, $f(x) := F(\chi_x - \mathbf{0}) = F(\chi_x)$. Conversely, for every real function $f: M \to \mathbb{R}$ with $f(\mathbf{0}) = \mathbf{0}$ define $F: \text{Mol}(M, d) \to \mathbb{R}$ extending f linearly. Formally, $F(m) = \sum_{i=1}^{n} c_i (f(x_i) - f(y_i))$ for every $m \in \sum_{i=1}^{n} c_i (x_i - y_i) \in$ $Mol(M, d)$. Note that for pointed metric spaces every molecule can be represented as $m = \sum_{i=1}^{n} r_i x_i = \sum_{i=1}^{n} r_i (x_{i} - \mathbf{0}).$ These observations are useful for example in the verification of Fact [2.2.](#page-2-1)

By $\text{Lip}_0(X)$ we denote the space of all Lipschitz functions $f: X \to \mathbb{R}$ satisfying $f(\mathbf{0}) = 0$. It is well known that $\text{Lip}_0(X)$ is a Banach space with respect to the natural norm $||f|| := Lip(f)$. Recall some well known important properties.

Fact 2.2. Let $(M, d, 0)$ be a pointed metric space. Then

- (1) $\mathfrak{F}(M)^* = \text{Lip}_0(M)$.
- (2) Weak-star topology on bounded subsets $\mathfrak{F}(M)^* = \mathrm{Lip}_0(X)$ coincides with the topology of pointwise convergence.
- (3) $||m||_d$ is the largest seminorm on Mol (M, d) such that $||\chi_x \chi_y|| \leq d(x, y)$. Moreover, $||\chi_x - \chi_y||_d = d(x, y)$. That is, $\chi: M \to \text{Mol}(M)$ is an isometric embedding.
- (4) (Universal property) Let V be a Banach space and $f \in \text{Lip}_0(M, V)$ there exists a unique bounded linear map $T_f \in L(\mathcal{F}(M), V)$ such that $f = T_f \circ \chi$ and $||T_f|| = ||f||_{\text{Lip}}.$
- (5) (Canonical linearization) Let $f: (M_1, 0) \rightarrow (M_2, 0)$ be a Lipschitz map between two pointed metric spaces extends to a unique continuous linear map $\bar{f}: \mathfrak{F}(M_1) \to \mathfrak{F}(M_2)$ such that $\bar{f} \circ \chi_1 = \chi_2 \circ f$.

3. Representation of dynamical systems on Lipschitz-free spaces

As before we denote by $(M, d, 0)$ a pointed metric space. Suppose that we have an isometric continuous left action $\pi: G \times M \to M$ of a topological group G on M such that $q\mathbf{0} = \mathbf{0}$ for every $q \in G$. Naturally extending this action to the normed space $Mol(M)$ of all molecules we get a continuous isometric linear action

$$
G \times \text{Mol}(M) \to \text{Mol}(M).
$$

Passing to the completion we obtain an unique continuous linear (isometric) extension

$$
G \times \mathcal{F}(M) \to \mathcal{F}(M).
$$

Let $h: G \to \text{Is}(\mathcal{F}(M))$ be the corresponding canonically defined continuous group homomorphism, where $\text{Is}(\mathcal{F}(M))$ is the topological group of all **linear** isometries (endowed with the strong operator topology). Note that if G is a subgroup of the topological group Is (M, d) (with the pointwise topology) then h is a topological group embedding. It follows that every pointed metric space with an isometric action (which fixes the distinguished point) admits a natural linearization on $\mathcal{F}(M)$. In Definition [3.2](#page-3-0) we deal with a different kind of linearization when the main target is the actions on the dual ball $B_{\mathcal{F}(M)^*}$.

Lemma 3.1. The induced dual action $\pi^*: G \times B_{\mathcal{F}(M)^*} \to B_{\mathcal{F}(M)^*}$ is continuous, where $B_{\mathfrak{F}(M)^*}$ is the weak-star compact unit ball in the dual space $\mathfrak{F}(M)^*$.

Proof. This is a particular case of a general well know fact (see, for example, [\[8,](#page-7-3) Fact 2.2) which is true for all isometric linear actions of G on Banach spaces V. More precisely, the dual action $G \times B_{V^*} \to B_{V^*}$ is continuous for every topological subgroup $G \subseteq Is(V)$ and every normed space V, where B_{V^*} is the weak-star compact unit ball. \Box

Definition 3.2. Let X be a topological G-space and M be a pointed metric space. A **representation** of (G, X) on $\mathfrak{F}(M)$ is a pair (h, α) where $h: G \to \text{Is}(M)$ is a continuous homomorphism and $\alpha: X \to B_{\mathfrak{F}(M)^*}$ is a weak-star continuous G-equivariant map.

Question 3.3. Let M be a some class of pointed metric spaces. Which dynamical systems (G, X) can be properly represented on $\mathcal{F}(M)$ for some $M \in \mathcal{M}$? Especially, whenever M somehow is related to the original topological space X.

Recall that (in view of Definition [1.1\)](#page-1-1) proper representation simply means that α is a topological embedding. Every properly representable G-space is G-compactifiable.

Remark 3.4. Note that there are sufficiently many representations of compact Gspaces on the Lipschitz-free spaces $\mathfrak{F}(M)$. Indeed, one may show that if K is a compact G-space then (G, K) admits a proper representation on $\mathfrak{F}(M)$, where $M := B_{C(K)}$ is the norm closed unit ball as the desired metric space (zero of the Banach space $C(K)$) is the distinguished point).

Question 3.5. For every $f \in B_{\mathcal{F}(M)^*}$ (individual 1-Lipschitz function on M) we have a compact G-space $K_f := cl_{w^*}(Gf) \subset B_{\mathcal{F}(M)^*}$. It would be interesting to study dynamical properties of such dynamical systems (G, K_f) .

Question 3.6. For every $f \in B_{\mathcal{F}(M)^*}$ and every $v \in M$ one may consider the corresponding **matrix coefficient** (which is bounded right uniformly continuous)

$$
m_{f,v} \colon G \to \mathbb{R}, \ g \mapsto f(gv).
$$

It would be interesting to study whether such functions on G belong to dynamically interesting class of functions. For instance, when $m_{f,v} \in \text{WAP}(G)$? When $m_{f,v} \in$ Asp(G) ? When $m_{f,v} \in \text{Tame}(G)$?

For the definitions of the algebras $WAP(G)$, $Asp(G)$, $Tame(G)$ and their roles in Banach representations theory, see for example, [\[4\]](#page-7-5).

Example 3.7. If d is a **stable metric** on G (that is, if it satisfies the double limit property of Grothendieck) then (making use the Grothendieck's criterion of WAP) one may show that $m_{\rho_a,v} \in \text{WAP}(G)$ for the matrix coefficient defined by any pair $v \in \text{Mol}(M)$ and $\rho_a \in B_{\mathcal{F}(M)^*}$, where $\rho_a(x) := d(a,x) - d(a,0)$ (as defined in Theorem [3.8](#page-5-0) below).

In the future we are going to study these (and similar) questions. In the present note we discuss the so called metric (hori)compactifications interprating it as a particular case of a representation in the sense of Definition [3.2](#page-3-0) and giving a partial response to general Question [3.3.](#page-3-2)

3.1. Metric equivariant compactifications. Recall that if (X, d) is a bounded metric space (not necessarily pointed), with a continuous G -action, then one may consider the following family of elementary (bounded) distance functions

(3.1)
$$
\Gamma := \{g_a \colon X \to \mathbb{R}, \ \gamma_a(x) := d(a, x)\}_{a \in X}.
$$

Let A_{γ} be a G-invariant closed unital subalgebra of $C_b(X)$ (the algebra of all continuous bounded functions with the sup-norm) generated by this family. Denote by $\gamma: X \to \hat{X}^{\gamma}$ the corresponding compactification (maximal ideal space). Then γ is a topological embedding because Γ separates points and closed subsets). In fact, γ is a G-compactification as it was mentioned in [\[9\]](#page-7-6). That is, there exists a continuous action $G \times \hat{X}^{\gamma} \to \hat{X}^{\gamma}$ which extends the given action on X. For some examples and applications (among others, for the Urysohn's sphere) we refer to [\[7\]](#page-7-7) and [\[12\]](#page-7-8). In particular, note that the Gromov compactification of the Urysohn sphere (S_U, d) can be identified with the greatest G -compactification of S_U with respect to the action of its Polish isometry group $G := \text{Is}(S_U)$.

Below we deal with a closely related general construction of the so called metric compactifications $m: M \to \widehat{M}$. This concept was introduced by M. Gromov but there are several (distinct versions in the literature). Note that m is always continuous injective but not necessarily an embedding. Relevant information about metric (hori)compactifications can be found, for example, in [\[10,](#page-7-9) [6,](#page-7-10) [2\]](#page-7-11).

Let us say that a point x_0 in (M, d) is equidistant if $d(x, x_0) = c_0 > 0$ is constant for every $x \in M \setminus \{x_0\}$. Clearly, then d is bounded, diam $(M, d) \leq 2c_0$. Conversely, for bounded metrics, one may adjoin a new point 0 which is equidistant. This also is very useful in view of actions because in this way any isometric G-action on a bounded metric G-space M can be naturally embedded into an isometric G-action on $M \cup \{0\}$ fixing the new isolated point. In this case assertion (3) of Theorem [3.8](#page-5-0) in fact speaks about the "original" non-pointed metric space M and its Gromov compactification.

Below $h: G \to \text{Is}(\mathcal{F}(M))$, as before, be the canonically defined continuous homomorphism induced by the action of G on $\mathfrak{F}(M)$.

Theorem 3.8. Let $(M, d, 0)$ be an isometric G-space. Define

$$
\rho \colon M \to (\mathfrak{F}(M)^*, w^*), \quad \rho(a) = \rho_a,
$$

where

$$
\rho_a(x) := d(a, x) - d(a, \mathbf{0}).
$$

- (1) Then the pair (h, ρ) is a well defined continuous injective representation of the G-space M on $\mathfrak{F}(M)$, with $\rho(\mathbf{0}) = 0$ _F and $||\rho(a)||_{\text{Lip}} = 1$ for every $a \in M \setminus \{\mathbf{0}\}.$
- (2) The induced continuous (injective) G-map

$$
\rho\colon M\to \widetilde{M}:=cl_{w^*}\rho(M)\subset B_{\mathfrak{F}(M)^*}
$$

is equivalent to the **metric** (hori)compactification of $(M, d, 0)$.

(3) If **O** is equidistant (or, equivalently, if there exists an equidistant point in M) then ρ is a topological embedding and the induced compactification

 $\rho: M \setminus \{\mathbf{0}\} \to cl_{w^*} \rho(M \setminus \{\mathbf{0}\})$

is equivalent to the **Gromov compactification** of $(M \setminus \{0\}, d)$.

Proof. (1) First shortly observe that ρ is well defined. We repeatedly use the equality $\mathcal{F}(M)^* = \text{Lip}_0(M)$ (Fact [2.2.](#page-2-1)1).

Indeed, $\rho_{\bf 0}(x) = 0$ for every $x \in M$. Hence, $\rho_{\bf 0} = \rho({\bf 0}) = 0$ _f. Also,

$$
|\rho_a(x) - \rho_a(y)| = |d(a, x) - d(a, \mathbf{0}) - (d(a, \mathbf{0}) - d(a, y))| \le d(x, y).
$$

Hence, $||\rho_a||_{\text{Lip}} \leq 1$ for every $a \in M$. Furthermore,

$$
|\rho_a(x) - \rho_a(a)| = |d(a, x) - d(a, 0) - d(a, 0) + d(a, a)| = d(a, x).
$$

Therefore, $||\rho_a||_{\text{Lip}} = ||\rho(a)||_{\text{Lip}} = 1$ for every $a \in M \setminus \{0\}.$

 ρ is injective. Indeed, let $a, b \in M$ and $\rho_a(x) = \rho_b(x)$ for every $x \in M$. Then, in particular, $\rho_a(a) = \rho_b(a)$ and $\rho_a(b) = \rho_b(b)$. So, $d(a, 0) - 0 = d(b, 0) - d(a, b)$ and $d(a, 0) - d(b, a) = d(b, 0) - 0$. Then we get $2d(a, b) = 0$. Hence, $a = b$.

For every $x \in M$ define the following function

$$
\varphi_x\colon M\to\mathbb{R},\ \varphi_x(a):=d(a,x)-d(a,0)=\rho_a(x).
$$

Then φ_x is bounded because $|\varphi_x(a)| \leq d(0, x)$ and continuous by

$$
|\varphi_x(a_1) - \varphi_c(a_2)| \leq 2d(a_1, a_2).
$$

Every function ρ_a can be identified with the following element of \mathbb{R}^M as follows:

$$
(\rho_a(x))_{x\in X} = (d(a,x) - d(a,0))_{x\in M} = (\varphi_x(a))_{x\in X} \in \mathbb{R}^M.
$$

Since $\varphi_x(a) := d(a,x) - d(a,0) = \rho_a(x)$, the function $\rho: M \to \mathbb{R}^M$, $a \mapsto \rho_a$ is the diagonal product of the following family of functions $\Phi := {\varphi_x : x \in M}$. Denote by τ_w the corresponding pointwise (weak) topology on $\rho(M)$ which coincides with the topology of the corresponding precompact uniformity μ_{Φ} on M.

As we already established, $\rho(M) \subset B_{\mathcal{F}(M)^*} \subset \text{Lip}_0(M)$ holds. Since $\rho(M)$ is norm bounded in $\text{Lip}_0(M)$, the weak-star topology inherits on $\rho(M)$ the pointwise topology (Fact [2.2.](#page-2-1)2). That is exactly the subspace topology τ_w of the product \mathbb{R}^M . Every $\varphi_x \colon M \to \mathbb{R}$ is continuous. Hence, $\tau_w \subseteq top(d)$. This implies that the injection $\rho: M \to B_{\mathcal{F}(M)^*}$ is continuous.

$$
\rho(ga)(x) = \rho_{ga}(x) = d(ga, x) - d(ga, 0) = d(a, g^{-1}x) - d(a, 0) = \rho_a(g^{-1}x) = (g\rho_a)(x)
$$

for every $x \in M$. For a description of the dual action see Definition [1.1.](#page-1-1)

(2) It is well known that the metric compactification $m: M \to M$ is the completion of the precompact uniformity μ_{Φ} on X generated by the family (of bounded) functions $\Phi := {\varphi_x : x \in M}$. See, for example, [\[2,](#page-7-11) Section 2.4].

(3) We have to show that ρ is a **topological embedding** of $(M, top(d))$ into the weak-star compact space $(B_{\mathcal{F}(M)^*}, w^*)$.

Since 0 is equidistant, there exists $c_0 > 0$ such that $d(x, 0) = c_0$ for every $x \in$ $M \setminus \{0\}$. Therefore, $\varphi_x(a) = d(a, x) - c_0$. We claim that the following family of functions

(3.2)
$$
\Gamma_0 := \{ \varphi_x \colon X \to \mathbb{R}, \ \varphi_x(a) = d(a, x) - c_0 \} \}_{x \in M}.
$$

separates points and closed subsets in M. Indeed, for every closed subset $B \subset M$ and a point $x_0 \notin B$ we have $\varphi_{x_0}(x_0) = -c_0$ and $\varphi_{x_0}(b) \ge c_1 - c_0$ for every $b \in B$, where $c_1 := d(x_0, B) > 0$. Hence, $\varphi_{x_0}(x_0) \neq cl(\varphi_{x_0}(B))$.

Clearly, the family $\Phi_X := {\{\varphi_x\vert_X : x \in X\}}$, with $X := M \setminus {\{0\}}$, generates the same unital subalgebra of $C_b(X)$ as the family

$$
\Gamma := \{ \gamma_a \colon X \to \mathbb{R}, \ \gamma_a(x) := d(a, x) \}_{a \in X}
$$

from Equation [3.1.](#page-4-0)

Remark 3.9.

- (1) One of the corollaries of Theorem [3.8](#page-5-0) is that for every isometric pointed metric G -space M the canonically defined representation (h, ρ) on its own Lipschitzfree space $\mathfrak{F}(M)$ is an injective representation of (G, M) which in fact induces the classical metric compactification.
- (2) The metric compactification m: $M \to \widehat{M}$ is always continuous and injective for every pointed metric space M but in general it is not a topological embedding. As an important sufficient condition, note that an important fact in metric geometry which asserts that m is a topological embedding for every complete geodesic and proper (the latter means that all closed balls are compact) metric space (M, d) .
- (3) The metric compactification is independent (up to the homeomorphism) of the choice of base point. This justifies the first line in assertion (3) of Theorem [3.8.](#page-5-0)
- (4) The topology of $m(M)$ inherited from M is the weak topology (in terms of [\[10\]](#page-7-9)) generated by the family Φ (see also [\[2,](#page-7-11) Remark 2.6]).
- (5) The continuity of the induced G-action on \hat{X} was verified in [\[2,](#page-7-11) Lemma 2.5]. This fact follows directly from the continuity of the dual actions Lemma [3.1.](#page-3-5)
