Safe and Stable Connected Cruise Control for Connected Automated Vehicles with Response Lag

Yuchen Chen, Gábor Orosz, and Tamas G. Molnar

Abstract-Controlling connected automated vehicles (CAVs) via vehicle-to-everything (V2X) connectivity holds significant promise for improving fuel economy and traffic efficiency. However, to deploy CAVs and reap their benefits, their controllers must guarantee their safety. In this paper, we apply control barrier function (CBF) theory to investigate the safety of CAVs implementing connected cruise control (CCC). Specifically, we study how stability, connection architecture, and the CAV's response time impact the safety of CCC. Through safety and stability analyses, we derive stable and safe choices of control gains, and show that safe CAV operation requires plant and head-to-tail string stability in most cases. Furthermore, the reaction time of vehicles-which is represented as a first-order lag-has a detrimental effect on safety. We determine the critical value of this lag, above which safe CCC gains do not exist. To guarantee safety even with lag while preserving the benefits of CCC, we synthesize safety-critical CCC using CBFs. With the proposed safety-critical CCC, the CAV can leverage information from connected vehicles farther ahead to improve its safety. We evaluate this controller by numerical simulation using real traffic data.

Index Terms—Connected automated vehicle, connected cruise control, safety-critical control, stability analysis, first-order lag

I. INTRODUCTION

THE promise of automated vehicles (AVs) to greatly improve safety, passenger comfort, fuel efficiency, and traffic efficiency has led to a surge of research and development on AVs in recent years. As a result, longitudinal controller designs for AVs such as adaptive cruise control (ACC) have been studied intensively [1], [2] and deployed extensively. Vehicleto-everything (V2X) connectivity, which enables connected automated vehicles (CAVs) to exchange information with other road users, can further enhance the performance of AVs. With more information about the surrounding traffic, strategies like cooperative adaptive cruise control (CACC) [3] enable platoons of CAVs to drive cooperatively to save fuel [4] and achieve string stability [5]. Additionally, connected cruise control (CCC) [6], which controls the motion of a single CAV based on the information shared by the preceding connected (but not necessarily automated) vehicles, outperforms ACC in experiments [7] and also shows other significant benefits, such as reduced traffic congestion [8] and improved fuel economy [9]. Alternatively, leading cruise control (LCC) [10]

Fig. 1. (a) A connected automated vehicle (CAV) responds to the preceding human-driven vehicles (HVs) and to the head connected human-driven vehicle (CHV) using vehicle-to-everything (V2X) connectivity and connected cruise control (CCC). (b-c) Behavior of the CCC with unsafe control parameter choice (blue), and the proposed safety-critical CCC that minimally modifies the above CCC to ensure safety using the safety filter (orange).

and *connected traffic control* (CTC) [11] utilize information from following vehicles to smooth the traffic flow.

Safety is the top priority when deploying AVs and CAVs. Recently, the safety of mixed traffic (including automated and human-driven vehicles) has been studied, considering reinforcement learning [12] and head-to-tail string stability analysis [13]. Furthermore, safety-critical controllers have been developed for AVs and CAVs with approaches including reachability analysis [14], formal methods [15], reinforcement learning [16], and model predictive control [17], [18]. Additionally, control barrier functions (CBFs) have gained popularity for safety-critical control. Some applications of CBFs include adaptive cruise control [19], [20], obstacle avoidance with AVs [21], lane changing [22], roundabout crossing [23], merging scenarios [24], and safe traffic control by CAVs [25], with experimental validations [26]. Notably, CBFs were used in [27] to establish safe CCC, and a thorough analysis was then conducted in [28]. A robust, safe CCC design was proposed in [29] with experimental validation on a heavy-duty truck. However, these studies predominantly focus on scenarios where the CAV responds solely to the immediate preceding vehicle, while the relationship between connectivity to multiple vehicles ahead and safety is yet to be explored. In addition, while safety-critical control for time delay systems with state delay has been addressed in previous studies such as [30]–[32], input delays are still not taken into account for safety-critical controller synthesis.

To address these gaps, our recent work [33] investigated the safety of CCC in connected vehicle networks, where

CAVs respond to the connected human-driven vehicles (CHVs) farther ahead via V2X connectivity, as illustrated in Fig. 1(a). Using safety charts, we provide a guideline to select safe control gains for existing CCC designs. Furthermore, we also proposed a safety-critical CCC method, which allows existing, efficient CCC algorithms to operate when it is safe and only minimally intervenes when danger appears to ensure safety; see Fig. 1(b-c). Compared to our previous work in [33], this paper contains the following contributions:

- We capture the response time of CAVs as a first-order lag applied to the control input and analyze how it affects the safety of existing CCC designs. Via safety charts, we show that the lag negatively impacts safety. We quantify a critical value of the lag for which safe choices of control gains cease to exist.
- We extend the safety analysis to cases with the general connectivity structure, where the CAV responds to multiple connected vehicles ahead of it, and potentially also utilizes information about their acceleration.
- Apart from studying safety, we also provide a detailed stability analysis for the general CCC designs mentioned above. Moreover, we study the interplay of stability and safety by comparing stability charts with safety charts, and we demonstrate that in most cases, existing CCC designs can achieve safety when the vehicle chain is both plant and head-to-tail string stable.
- To overcome the limitations of existing CCC methods, we propose a safety-critical CCC algorithm based on CBF theory that takes the lag into account and guarantees safety. This is achieved by minimally modifying existing CCC laws that have high performance (i.e., provide plant and head-to-tail string stability) but lack safety guarantees.
- We evaluate the performance of safety-critical CCC via numerical simulations, while utilizing real traffic data for the motions of human-driven vehicles. Through simulation, we show that the proposed controller can leverage connectivity to improve safety, and it guarantees safety regardless of the lag and connectivity architecture while preserving the high performance of CCC.

The rest of this paper is organized as follows. In Section II, we introduce longitudinal vehicle dynamics with first-order lag and the framework of CCC. In Section III, we derive conditions for the plant stability and head-to-tail string stability of CCC. In Section IV, we provide background on CBFs. In Section V, we establish safety conditions for existing CCC laws, and visualize them via safety charts. Next, we propose *safety-critical CCC* with lag, and demonstrate its behavior using numerical simulations. Finally, we conclude our results in Section VI.

II. CONNECTED CRUISE CONTROL

Consider a setup where a connected automated vehicle (CAV) is controlled to follow a chain of human-driven vehicles (HVs) on a single lane while responding to connected humandriven vehicles (CHVs) farther ahead. The CAV uses on-board sensors to evaluate its own speed v_0 , the preceding HV's speed v_1 , and the distance D_0 between them. Additionally, the CAV also receives the CHVs' speeds v_k through vehicle-to-everything (V2X) connectivity. An illustration of this setup is depicted in Fig. 1(a), where the CAV is only linked with one CHV that is n + 1 vehicles ahead.

We represent the motion of the HVs using the dynamics:

$$D_{i}(t) = v_{i+1}(t) - v_{i}(t),$$

$$\dot{v}_{i}(t) = a_{i}(t),$$

$$a_{i}(t) = u_{i}(t - \tau),$$

(1)

for $i \in \{1, ..., n\}$, where a_i is the actual acceleration, u_i is the desired one, and τ captures driver reaction time and powertrain delays. We use the optimal velocity model (OVM) to characterize the HVs' driving behavior during the carfollowing task [34]:

$$u_{i} = A_{i} (V_{i}(D_{i}) - v_{i}) + B_{i} (v_{i+1} - v_{i}), \qquad (2)$$

for $i \in \{1, ..., n\}$. In this model, each HV's desired acceleration is determined by the speed difference with gain B_i and the distance with gain A_i and the range policy:

$$V_i(D) = \min\{\kappa_i(D - D_{\rm st}), v_{\rm max}\},\tag{3}$$

for $i \in \{1, ..., n\}$. This policy outlines a target velocity determined by the distance to the vehicle ahead, which is zero at the standstill distance D_{st} and grows linearly with gradient κ_i up to the speed limit v_{max} .

To describe the CAV's dynamics, we incorporate its response time ξ as a first-order lag:

$$\dot{D}_{0}(t) = v_{1}(t) - v_{0}(t),
\dot{v}_{0}(t) = a_{0}(t),
\dot{a}_{0}(t) = \frac{1}{\xi} (u_{0}(t) - a_{0}(t)).$$
(4)

The CAV executes the acceleration command u_0 , while its actual acceleration a_0 has lag ξ . Note that when $\xi \rightarrow 0$, $u_0(t) \equiv a_0(t)$ and system (4) can be simplified to the first two equations. For simplicity, we neglect the rolling and air resistance of the CAV, which could potentially reduce speed and improve safety. We also omit input constraints for the CAV's dynamics, since well-tuned controllers can successfully prevent the input from exceeding the physical limit, as will be shown in the following content. Notably, safety-critical control with input constraints is an open problem to be explored. This is addressed in the context of control barrier functions, for example, in [35]–[37].

For car-following purposes, we implement a desired controller for the CAV, $u_0 = k_d(x)$, which responds to the state $x = \begin{bmatrix} D_0 & v_0 & a_0 & v_1 \end{bmatrix}^{\top}$. Specifically, we select the *connected cruise control* (CCC) strategy, which was first presented in [6] and validated through experiments in [7]. Here we follow [6], but with slightly changed notation that fits our purposes:

$$k_{\rm d}(x) = A \big(V(D_0) - v_0 \big) + B_1 \big(W(v_1) - v_0 \big) + \sum_{k \in \Phi} B_k \big(W(v_k) - v_0 \big).$$
(5)

Fig. 2. Simulations of system (4) for $\xi = 0$ s (green) and $\xi = 0.6$ s (orange) using CCC (5) with n = 1, where a CAV performs an emergency brake to avoid crashing with the stopped CHV.

TABLE I PARAMETERS OF THE NUMERICAL CASE STUDIES

Vehicle	Variable	Symbol	Value	Unit
All	speed limit	v_{\max}	30	m/s
	acceleration limit	$D_{ m st} \ (a_{ m min}, a_{ m max})$	5 (7,3)	m m/s^2
HV	delay	au	0.9	s
	range policy gradient	$\kappa_{ m h}$	0.6	1/s
	driver parameters	$(A_{ m h},B_{ m h})$	(0.1, 0.6)	1/s
CAV	range policy gradient	κ	0.6	1/s
	safe gains (point P)	(A, B_1, B_{n+1})	(0.6, 0.53, 0.03)	1/s
	unsafe gains (point Q)	(A, B_1, B_{n+1})	(0.6, 0.53, 0.5)	1/s
	safe distance	$D_{\rm sf}$	1	m
	inverse time headway	$\kappa_{ m sf}$	0.6	1/s
	speed difference limit	\overline{v}	15	m/s
	CBF parameter	γ	1	1/s
	eCBF parameter	$\gamma_{ m e}$	1	1/s
CHV	speed perturbation	$v_{\rm pert}$	15	m/s

CCC responds to the distance from and velocity of the vehicle ahead with gains A and B_1 , respectively, and also to the speeds of CHVs with gains B_k (k > 1). Here, v_k denotes the speed of the CHV, which is k vehicles ahead, and Φ denotes the set of indices corresponding to the CHVs whose velocity are accessible to the CAV via connectivity. For instance, in Fig. 1(a), the CAV only connects to CHV #n+1, thus $\Phi = \{n + 1\}$. In this case, (5) becomes:

$$k_{\rm d}(x) = A(V(D_0) - v_0) + B_1(W(v_1) - v_0) + B_{n+1}(W(v_{n+1}) - v_0).$$
(6)

When the CAV only responds to the preceding vehicle $(\Phi = \emptyset)$, CCC (5) only contains distance and speed difference terms with gains A and B_1 like the OVM (2). CAV implements the range policy:

$$V(D) = \min\{\kappa(D - D_{\rm st}), v_{\rm max}\},\tag{7}$$

and the speed policy:

$$W(v) = \min\{v, v_{\max}\},\tag{8}$$

to ensure it does not exceed the speed limit.

Notice that CCC (5) does not provide formal safety guaran-

tees. This is illustrated in Fig. 2, where CCC, given by (4,5) with $\xi = 0$ s, 0.6 s and n = 1, is simulated in a 2-vehicle scenario shown in panel (a). We use A = 0.6, $B_1 = 0.5$ for CCC (5) and other parameters listed in Table I. The preceding CHV stops suddenly, and the CAV responds to it with a lag; see panel (c). As shown by panel (b), the CAV closely follows the range policy V(D) if the lag is small (green). However, as the lag is increased (orange), the CAV maintains shorter distance and becomes unsafe. Motivated by this, we will formally analyze how lag affects the safety of CAVs and calculate the critical lag above which safe choices of the gains A, B_1 and B_k do not exist for CCC (5). Before the safety analysis, first we discuss stability analysis as preliminary.

III. STABILITY ANALYSIS

Realizing stable behavior for the CAV is a fundamental requirement for CCC. In this section, we derive the plant and head-to-tail string stability conditions [6], [38] for the vehicle chain containing one CAV at the tail and multiple HVs and CHVs in front, see Fig. 1(a). Plant stability indicates that a vehicle is able to approach a constant-speed equilibrium in an asymptotically stable manner. Head-to-tail string stability means that velocity fluctuations are attenuated as they propagate from the head to the tail vehicle along the chain. Plant and head-to-tail string stability can be evaluated by calculating the so-called head-to-tail transfer function [6], which is established in the Laplace domain for the corresponding linearized dynamics.

To derive the head-to-tail transfer function, first we linearize the systems (1,2) and (4,5) around the equilibrium:

$$D_i(t) \equiv D_i^*, \quad v_i(t) \equiv v^*, \quad a_i(t) \equiv 0, \tag{9}$$

for $i \in \{0, ..., n\}$, where all vehicles drive at the uniform equilibrium speed v^* , while maintaining equilibrium distance D_i^* given by $v^* = V(D_0^*) = V_i(D_i^*)$ for $i \in \{1, ..., n\}$.

Then we define perturbations around the equilibrium:

$$\tilde{D}_i = D_i - D_i^*, \quad \tilde{v}_i = v_i - v^*, \quad \tilde{a}_i = a_i,$$
 (10)

for $i \in \{0, ..., n\}$, and consider state vectors with these perturbations as $x_0 = [\tilde{D}_0 \ \tilde{v}_0 \ \tilde{a}_0]^{\top}$ for the CAV and $x_i = [\tilde{D}_i \ \tilde{v}_i]^{\top}$ for the HVs $i \in \{1, ..., n\}$. The speed fluctuations are obtained as:

$$\tilde{v}_0 = \mathbf{c}_0 x_0, \quad \mathbf{c}_0 = \begin{bmatrix} 0 & 1 & 0 \end{bmatrix}, \\
\tilde{v}_i = \mathbf{c}_i x_i, \quad \mathbf{c}_i = \begin{bmatrix} 0 & 1 \end{bmatrix}.$$
(11)

After substituting (10) into (1,2) and (4,5), we linearize the nonlinear functions V(.) and W(.) by assuming that $0 < v_i < v_{\text{max}}$, and derive the corresponding linearized models:

$$\dot{x}_{0}(t) = \mathbf{a}_{0}x_{0}(t) + \mathbf{b}_{0,1}\tilde{v}_{1}(t) + \sum_{k\in\Phi} \mathbf{b}_{0,k}\tilde{v}_{k}(t),$$

$$\dot{x}_{i}(t) = \mathbf{a}_{i}x_{i}(t) + \mathbf{a}_{i\tau}x_{i}(t-\tau)$$

$$+ \mathbf{b}_{i}\tilde{v}_{i+1}(t) + \mathbf{b}_{i\tau}\tilde{v}_{i+1}(t-\tau), \quad \forall i \in \{1,...,n\},$$
(12)

with coefficient matrices $\mathbf{a}_0, \mathbf{b}_{0,1}, \mathbf{b}_{0,k}, \mathbf{a}_i, \mathbf{a}_{i\tau}, \mathbf{b}_i, \mathbf{b}_{i\tau}$ shown in (55) in Appendix VI-A. By applying the Laplace transform with zero initial condition, (11,12) lead to:

$$\tilde{V}_{0}(s) = T_{0,1}(s)\tilde{V}_{1}(s) + \sum_{k \in \Phi} T_{0,k}(s)\tilde{V}_{k}(s),$$

$$\tilde{V}_{1}(s) = \prod_{i=1}^{n} T_{i,i+1}(s)\tilde{V}_{n+1}(s),$$

$$\tilde{V}_{k}(s) = \prod_{i=k}^{n} T_{i,i+1}(s)\tilde{V}_{n+1}(s).$$
(13)

Here $\tilde{V}_0(s)$, $\tilde{V}_1(s)$, $\tilde{V}_k(s)$ and $\tilde{V}_{n+1}(s)$ denote the Laplace transforms of the speed perturbation of the CAV \tilde{v}_0 , the preceding vehicles \tilde{v}_1 , \tilde{v}_k and the head vehicle \tilde{v}_{n+1} , respectively, while the link transfer functions are defined as:

$$T_{0,1}(s) = \mathbf{c}_0 (s\mathbf{I} - \mathbf{a}_0)^{-1} \mathbf{b}_{0,1},$$

$$T_{0,k}(s) = \mathbf{c}_0 (s\mathbf{I} - \mathbf{a}_0)^{-1} \mathbf{b}_{0,k},$$

$$T_{i,i+1}(s) = \mathbf{c}_i (s\mathbf{I} - \mathbf{a}_i - \mathbf{a}_{i\tau} e^{-s\tau})^{-1} (\mathbf{b}_i + \mathbf{b}_{i\tau} e^{-s\tau}),$$
(14)

for $i \in \{1, ..., n\}$ and $k \in \Phi$; see [6]. These link transfer functions can be obtained through the substitution of the coefficient matrices in (55), and their detailed expression can be found in (56) in Appendix VI-A.

The overall response of the vehicle chain considering speed perturbations from the head vehicle $\tilde{V}_{n+1}(s)$ to the tail vehicle $\tilde{V}_0(s)$ can be described by:

$$\tilde{V}_0(s) = G_{0,n+1}(s)\tilde{V}_{n+1}(s), \tag{15}$$

where the head-to-tail transfer function can be expressed as:

$$G_{0,n+1}(s) = T_{0,1}(s) \prod_{i=1}^{n} T_{i,i+1}(s) + \sum_{k \in \Phi} \left(T_{0,k}(s) \prod_{i=k}^{n} T_{i,i+1}(s) \right).$$
(16)

Considering the case shown in Fig. 1(a), i.e., CCC (6) with $\Phi = \{n + 1\}$, (16) simplifies to:

$$G_{0,n+1}(s) = T_{0,1}(s) \prod_{i=1}^{n} T_{i,i+1}(s) + T_{0,n+1}(s).$$
(17)

Using the head-to-tail transfer function, we can analyze the plant stability and head-to-tail string stability of the vehicle chain [39]. Plant stability is associated with the characteristic equation:

$$D(G_{0,n+1}(s)) = 0, (18)$$

where D(.) denotes the denominator. Plant stability is achieved when all characteristic roots have a negative real part, i.e., $\operatorname{Re}(s_m) < 0$, $\forall m \in \mathbb{N}$. If a real root s = 0 is located on the imaginary axis, the system reaches the plant stability boundary:

$$D(G_{0,n+1}(0)) = 0.$$
(19)

Alternatively, the stability boundary is also reached if a complex conjugate pair of roots $s = \pm j\Omega$, with $j^2 = -1$ and $\Omega > 0$, is located at the imaginary axis, yielding:

$$\operatorname{Re}(\operatorname{D}(G_{0,n+1}(\mathrm{j}\Omega))) = 0,$$

$$\operatorname{Im}(\operatorname{D}(G_{0,n+1}(\mathrm{j}\Omega))) = 0,$$
(20)

where Re(.) and Im(.) denote the real and imaginary part, respectively.

Head-to-tail string stability, on the other hand, describes whether velocity fluctuations are mitigated along the vehicle chain. According to (15), a velocity perturbation with frequency $\omega > 0$ from the head vehicle will be amplified by the ratio $|G_{0,n+1}(j\omega)|$ when reaching the tail vehicle. Therefore, head-to-tail string stability can be achieved if and only if:

$$|G_{0,n+1}(\mathbf{j}\omega)| < 1, \ \forall \omega > 0.$$

$$(21)$$

Equation (21) is equivalent to $P(\omega) > 0$ with:

$$P(\omega) := \frac{1}{\omega^2} \left(\mathbf{D}(|G_{0,n+1}(\mathbf{j}\omega)|^2) - \mathbf{N}(|G_{0,n+1}(\mathbf{j}\omega)|^2) \right), \quad (22)$$

where D(.) and N(.) denote denominator and numerator. For $\omega \rightarrow 0$, the string stability boundaries can be obtained by:

$$\lim_{\omega \to 0} P(\omega) = 0. \tag{23}$$

For $\omega > 0$, a set of string stability boundaries, parameterized by the wave number $K \in [0, 2\pi)$, is provided in [40]:

$$G_{0,n+1}(j\omega) = \frac{n_0(\omega) + jn_1(\omega)}{d_0(\omega) + jd_1(\omega)} = e^{-jK}, \qquad (24)$$

where $n_0(\omega)$ and $n_1(\omega)$ are the real and imaginary parts of $N(G_{0,n+1}(j\omega))$ while $d_0(\omega)$ and $d_1(\omega)$ are those of $D(G_{0,n+1}(j\omega))$.

Overall, (19,20) define the plant stability boundaries, while (23,24) specify the head-to-tail string stability boundaries, as a function of the CCC parameters such as A, B_1 , B_k . Appendix VI-A provides the detailed formulas for these boundaries. Using the expressions for the stability boundaries, one can construct *stability charts* to illustrate the regions of the control parameters that provide plant and head-to-tail string stability for a vehicle chain, thus aiding stable controller design.

Stability charts in the (A, B_1) and (B_1, B_2) planes are provided in Fig. 3 for the scenario where a CAV responds to the CHV two vehicles ahead, using the parameters in Table I. Note that we consider every HV to be identical with $A_i = A_h, B_i = B_h$ in (2) and $\kappa_i = \kappa_h$ in (3) for $i \in \{1, ..., n\}$ in the following examples of stability charts. In panels (a-b), the head-to-tail string stable region (blue) is enclosed by the boundaries (23) (blue lines) and (24) (rainbow colored curves for various values of K). This region can be concisely depicted as the string stable domains in panels (c-d). The plant stable domains (red) are also plotted below the string stable domains, with boundaries determined by (19,20). Note that the vehicle chain is string stable only when it is plant stable.

IV. BACKGROUND ON CONTROL BARRIER FUNCTIONS

In this section, we revisit the theory of control barrier functions, which is used to construct the safety of the CCC (5). Consider a control-affine system:

$$\dot{x} = f(x) + g(x)u, \tag{25}$$

where $x \in \mathbb{R}^n$, $u \in \mathbb{R}^m$ denote the state and the input, respectively, and $f : \mathbb{R}^n \to \mathbb{R}^n$ and $g : \mathbb{R}^n \to \mathbb{R}^{n \times m}$ are locally Lipschitz continuous functions representing the dynamics. The

Fig. 3. Stability charts of the CCC (4,6) for $\xi = 0.2$ s and n = 1 in (b) (A, B_1) plane, (c) (B_1, B_2) plane. (d-e) Simplified string stable domains, along with plant stable regions.

closed-loop system is established given a locally Lipschitz continuous controller $k : \mathbb{R}^n \to \mathbb{R}^m$, u = k(x):

$$\dot{x} = f(x) + g(x)k(x), \tag{26}$$

where x(t) represents the solution starting from the initial condition $x(t_0)$.

A safe set S is defined to determine the safety of system (26):

$$\mathcal{S} = \left\{ x \in \mathbb{R}^n : h(x) \ge 0 \right\},\tag{27}$$

where $h: \mathbb{R}^n \to \mathbb{R}$ is a continuously differentiable function. With that, system (26) is considered safe w.r.t. S if $x(t_0) \in S \implies x(t) \in S, \forall t \ge 0$, and its safety can be guaranteed by satisfying Nagumo's theorem [41] given below.

Theorem 1 ([41]). Let h satisfy $\nabla h(x) \neq 0$ for all $x \in \mathbb{R}^n$ such that h(x) = 0. System (26) is safe w.r.t. S if and only if:

$$\dot{h}(x,k(x)) \ge 0, \quad \forall x \in \mathbb{R}^n \text{ s.t. } h(x) = 0,$$
 (28)

where:

$$\dot{h}(x,k(x)) = \underbrace{\nabla h(x)f(x)}_{L_fh(x)} + \underbrace{\nabla h(x)g(x)}_{L_gh(x)}k(x), \quad (29)$$

and $L_f h(x)$ and $L_g h(x)$ denote the Lie derivatives.

Condition (28) is established at the boundary of S, i.e., h(x) = 0, which prevents the system from leaving the safe set. However, it does not specify the system behavior within S, i.e., h(x) > 0. To address this, *control barrier functions* (CBFs) [42] have been proposed to enable safety-critical controller synthesis for (25).

Definition 1 ([42]). Function *h* is a *control barrier function* for (25) on S if there exists $\alpha \in \mathcal{K}^{e}$ such that for all $x \in S$:

$$\sup_{u \in \mathbb{R}^m} \dot{h}(x, u) > -\alpha(h(x)).$$
(30)

Remark 1. A continuous function $\alpha : \mathbb{R} \to \mathbb{R}$ is of extended class- \mathcal{K} ($\alpha \in \mathcal{K}^{e}$) if it is strictly increasing and $\alpha(0) = 0$. For example, the extended class- \mathcal{K} function α is often chosen to be a linear function, $\alpha(r) = \gamma r$, with some $\gamma > 0$.

Theorem 2 ([42]). If h is a CBF for (25) on S, then any locally Lipschitz continuous controller k that satisfies:

$$\dot{h}(x,k(x)) \ge -\alpha(h(x)) \tag{31}$$

for all $x \in S$ renders (26) safe w.r.t. S.

CBFs are often employed in safety filters that minimally modify a desired but not necessarily safe controller $k_d : \mathbb{R}^n \to \mathbb{R}^m$ to a safe one, by solving the following quadratic programming problem with constraint (31):

$$k(x) = \underset{u \in \mathbb{R}^{m}}{\operatorname{argmin}} \quad \|u - k_{d}(x)\|^{2}$$

s.t. $\dot{h}(x, u) \ge -\alpha(h(x)).$ (32)

The closed form solution of (32) was given in [29] as:

$$k(x) = \begin{cases} k_{\rm d}(x) + \max\{0, \eta(x)\} \frac{L_g h(x)^{\top}}{\|L_g h(x)\|^2}, & \text{if } L_g h(x) \neq 0, \\ k_{\rm d}(x), & \text{if } L_g h(x) = 0, \end{cases}$$

$$\eta(x) = -L_f h(x) - L_g h(x) k_{\rm d}(x) - \alpha h(x). \tag{33}$$

For scalar input u like in (4), the safety filter simplifies to:

$$k(x) = \begin{cases} \min \{k_{\rm d}(x), k_{\rm s}(x)\}, & \text{if } L_g h(x) \le 0, \\ k_{\rm d}(x), & \text{if } L_g h(x) = 0, \\ \max \{k_{\rm d}(x), k_{\rm s}(x)\}, & \text{if } L_g h(x) \ge 0, \end{cases}$$
(34)

with:

$$k_{\rm s}(x) = -\frac{L_f h(x) + \alpha(h(x))}{L_g h(x)}.$$
(35)

Note that when $L_gh(x) \equiv 0$, the safety of the system (26) is not directly affected by the controller k(x), according to (29). Therefore, h is neither a valid CBF nor applicable for synthesizing safety-critical controllers. In such a case, an *extended CBF* can be constructed [43]–[45]:

$$h_{\rm e}(x) = L_f h(x) + \alpha \big(h(x) \big), \tag{36}$$

which is associated with the *extended safe set* S_e :

$$\mathcal{S}_{\mathbf{e}} = \{ x \in \mathbb{R}^n : h_{\mathbf{e}}(x) \ge 0 \}.$$
(37)

Condition (31) is satisfied when the system remains within S_e . Therefore, safety w.r.t. the intersection $S \cap S_e$ of the two sets can be established as follows.

Corollary 1 ([44]). If $L_gh(x) \equiv 0$ and h_e in (36) is a CBF for (25) on S_e with $\alpha_e \in \mathcal{K}^e$, then any locally Lipschitz continuous controller k that satisfies:

$$\dot{h}_{\rm e}(x,k(x)) \ge -\alpha_{\rm e}(h_{\rm e}(x)) \tag{38}$$

for all $x \in S_e$ renders (26) safe w.r.t. $S \cap S_e$.

Note that similar to Theorem 2, α_e can be chosen, for example, to be linear as $\alpha_e(r) = \gamma_e r$ with $\gamma_e > 0$.

Accordingly, Nagumo's theorem (28) is conducted at the boundary of $S \cap S_e$, specifically when h(x) = 0 and $h_e(x) \ge 0$, or when $h_e(x) = 0$ and $h(x) \ge 0$. Note that the former case implies $\dot{h}(x, k(x)) \ge 0$. It has already satisfied condition (28), and thereby requires no further analysis. The safety condition for the latter case is given as follows.

Corollary 2 ([28]). Let $L_gh(x) \equiv 0$ and h_e in (36) satisfy $\nabla h_e(x) \neq 0$ for all $x \in \mathbb{R}^n$ such that $h_e(x) = 0$. System (26) is safe w.r.t. $S \cap S_e$ if:

$$\dot{h}_{\mathrm{e}}(x,k(x)) \ge 0, \quad \forall x \in \mathbb{R}^n \text{ s.t. } h_{\mathrm{e}}(x) = 0 \text{ and } h(x) \ge 0.$$
(39)

For scalar input u, as in system (4), (39) is equivalent to:

 $k_{\mathrm{s}}(x) - k_{\mathrm{d}}(x) \ge 0, \quad \forall x \in \mathbb{R}^n \text{ s.t. } h_{\mathrm{e}}(x) = 0 \text{ and } h(x) \ge 0.$ (40)

where:

$$k_{\rm s}(x) = -\frac{L_f h_{\rm e}(x) + \alpha_{\rm e} \left(h_{\rm e}(x)\right)}{L_g h_{\rm e}(x)},\tag{41}$$

cf. (35), and formula (34) can be used as safety filter.

V. SAFE CONNECTED CRUISE CONTROL

In this section, we first investigate the safety of the nominal CCC (5) via Corollary 2, then modify the nominal CCC to propose a safety-critical CCC law via Corollary 1.

A. Safe Nominal CCC Design

Now we analyze the safety of the CAV dynamics (4) executing the nominal CCC (5) based on condition (40), and propose a guideline for safe nominal CCC design.

First, we append the expression of the front vehicle's acceleration, i.e., $\dot{v}_1(t) = a_1(t)$, to the CAV dynamics (4), and write the system in the form of (25) with:

$$x = \begin{bmatrix} D_0 \\ v_0 \\ a_0 \\ v_1 \end{bmatrix}, \quad f(x) = \begin{bmatrix} v_1 - v_0 \\ a_0 \\ -\frac{a_0}{\xi} \\ a_1 \end{bmatrix}, \quad g(x) = \begin{bmatrix} 0 \\ 0 \\ \frac{1}{\xi} \\ 0 \end{bmatrix}.$$
 (42)

Then, we select function h to characterize the CAV's safety. Several safety criteria were introduced in [28]. In this analysis, we adopt the strictest criterion, which mandates maintaining the *time headway* D_0/v_0 of the CAV above a specified safe threshold defined by $T_{\rm h} = 1/\kappa_{\rm sf}$:

$$h(x) = \kappa_{\rm sf} (D_0 - D_{\rm sf}) - v_0, \tag{43}$$

where $D_{\rm sf}$ denotes the safe standstill distance. This leads to:

$$\nabla h(x) = \begin{bmatrix} \kappa_{\rm sf} & -1 & 0 & 0 \end{bmatrix} \neq 0,$$

$$L_f h(x) = \kappa_{\rm sf}(v_1 - v_0) - a_0, \quad L_g h(x) \equiv 0.$$
(44)

Since $L_g h(x) \equiv 0$, the extended CBF in (36) can be constructed as:

$$h_{\rm e}(x) = \kappa_{\rm sf}(v_1 - v_0) - a_0 + \gamma \big(\kappa_{\rm sf}(D_0 - D_{\rm sf}) - v_0\big), \quad (45)$$

Fig. 4. Safety charts of the nominal CCC (5) when the CAV responds to the vehicle immediately ahead of it; see panel (a). The time headway criterion (43) is considered for (b) different CAV lags ξ in system (4) and (c) different bounds \bar{v} on the speed difference in (49) with $\xi = 0.15$ s.

where $\gamma > 0$ denotes the coefficient of the linear extended class- \mathcal{K} function $\alpha(r) = \gamma r$. Then, we have:

$$\nabla h_{\mathbf{e}}(x) = \begin{bmatrix} \gamma \kappa_{\mathrm{sf}} & -\kappa_{\mathrm{sf}} - \gamma & -1 & \kappa_{\mathrm{sf}} \end{bmatrix} \neq 0, \\
L_f h_{\mathbf{e}}(x) = \kappa_{\mathrm{sf}}(a_1 - a_0) + a_0/\xi + \gamma \big(\kappa_{\mathrm{sf}}(v_1 - v_0) - a_0\big), \\
L_g h_{\mathbf{e}}(x) = -1/\xi < 0.$$
(46)

Hence, Corollary 1 and 2 hold, i.e., (40) can be applied for safety analysis, whereas the safety filter (34) becomes:

$$k(x) = \min\{k_{\rm d}(x), k_{\rm s}(x)\},$$
 (47)

while (41) reads:

$$k_{\rm s}(x) = (1 - \xi \kappa_{\rm sf})a_0 + \xi \kappa_{\rm sf}a_1 + \xi \gamma \big(\kappa_{\rm sf}(v_1 - v_0) - a_0\big) + \xi \gamma_{\rm e} \Big(\kappa_{\rm sf}(v_1 - v_0) - a_0 + \gamma \big(\kappa_{\rm sf}(D_0 - D_{\rm sf}) - v_0\big)\Big).$$
(48)

where $\gamma_{\rm e} > 0$ denotes the coefficient of the linear extended class- \mathcal{K} function $\alpha_{\rm e}(r) = \gamma_{\rm e} r$.

To analyze the safety of the nominal CCC (5), we apply Corollary 2. Specifically, by analyzing when condition (40) holds, safe choices of controller gains A, B_1 and B_k , $\forall k \in \Phi$ can be derived as follows.

Theorem 3. System (4) with $u_0 = k_d(x)$ given by (5) and $A \ge 0$, $B_1 \ge 0$, $B_k \ge 0$, $\forall k \in \Phi$ is safe w.r.t. $S \cap S_e$ given by (27,37,43,45) if $v_0 \ge 0$, $|v_1 - v_0| \le \overline{v}$, $|v_k - v_0| \le \overline{v}$, $\forall k \in \Phi$ with some $\overline{v} > 0$, $a_1 \ge -a_{\min}$ with some $a_{\min} > 0$, $D_{st} > D_{sf}$, $\kappa_{sf} \ge \kappa > 0$, $\gamma > 0$ and:

$$A \leq \frac{(1 - \xi \kappa_{\rm sf})^2}{4\xi} - \xi \left(\gamma - \frac{1 - \xi \kappa_{\rm sf}}{2\xi}\right)^2,$$

$$A \geq \frac{\left(|\kappa_{\rm sf} - \xi \kappa_{\rm sf}^2 - B_1| + \sum_{k \in \Phi} B_k\right) \bar{v} + \xi \kappa_{\rm sf} a_{\rm min}}{\kappa (D_{\rm st} - D_{\rm sf})}.$$
(49)

Remark 2. The upper bound of A in Theorem 3 depends on γ , which can be chosen as $\gamma = (1 - \xi \kappa_{\rm sf})/(2\xi)$ to achieve the highest upper bound, i.e., largest region of safe control gains. In this case, $1/\xi > \kappa_{\rm sf}$ should be satisfied to guarantee $\gamma > 0$. Unless specified otherwise, we consider $\gamma = (1 - \xi \kappa_{\rm sf})/(2\xi)$ and $1/\xi > \kappa_{\rm sf}$ in the following calculations.

Safe choices of control gains do not exist if the lag ξ exceeds a critical value ξ_{cr} . This value can be derived using (49).

Fig. 5. Safety charts of the nominal CCC (6) when the CAV responds to the CHV two vehicles ahead (n = 1), see panel (a). The time headway criterion (43) is considered for the lag (b-c) $\xi = 0$ s; (d-e) $\xi = 0.15$ s; (f-g) $\xi = 0.2$ s in CAV system (4).

Corollary 3. Safe control gains exist only if:

$$\xi \le \xi_{\rm cr} = \frac{1}{\kappa_{\rm sf} + 2\sqrt{\frac{\kappa_{\rm sf}a_{\rm min}}{\kappa(D_{\rm st} - D_{\rm sf})}}}.$$
(50)

Please refer to Appendix VI-B and Appendix VI-C for the proofs of Theorem 3 and Corollary 3.

Remark 3. Based on (49), for unbounded velocity difference $\bar{v} \rightarrow \infty$, the safe region becomes the single line segment:

$$\frac{\xi \kappa_{\rm sf} a_{\rm min}}{\kappa (D_{\rm st} - D_{\rm sf})} \le A \le \frac{(1 - \xi \kappa)^2}{4\xi},$$

$$B_1 = \kappa_{\rm sf} - \xi \kappa_{\rm sf}^2, \ B_k = 0, \ \forall k \in \Phi.$$
(51)

Fig. 4(b-c) depicts the safety condition (49) for the situation in Fig. 4(a) when the CAV only responds to the preceding CHV using CCC (5) with $\Phi = \emptyset$. They are represented under varying lags ($\xi = 0$ s, 0.15 s, 0.2 s, 0.25 s) and speed difference limits ($\bar{v} = 5$ m/s, 10 m/s, 15 m/s, 25 m/s), respectively, using the parameters from Table I. These plots are called *safety charts* [27] [28], where the safe domain (green) indicates safe choices of CCC parameters. For this case, the safe region is triangular. In panel (b), as the lag increases, the upper horizontal boundary is moving down and the lower V-shaped boundary is moving towards smaller B_1 and larger A, which makes the safe region shrink until it becomes a point at the critical lag $\xi_{cr} = 0.3$ s obtained by (50). In panel (c), as the speed difference limit \bar{v} increases, the V-shaped safe region gradually narrows to the green dashed line given by (51). This suggests that larger speed difference between the CAV and the CHV makes it more difficult to find safe CCC parameters.

The plant and head-to-tail string stability domains are also visualized using red and blue shading, respectively, in Fig. 4(b-c). Their boundaries are given by (60,61) for plant stability and (65,68) for head-to-tail string stability with $B_{n+1} = 0$, see Appendix VI-A. Notably, except for extremely small \bar{v} , the safe domain consistently lies within the plant and string stable region, indicating that safe CCC parameters also achieve plant and string stability for this case.

To show how V2X connectivity affects the safety of the CAVs, we examine a scenario presented in Fig. 5(a), where the CAV responds not only to the preceding HV but also to the CHV two vehicles ahead using CCC (6) with n = 1. The safety condition (49) is visualized in the (B_1, A) plane for various B_2 values, and in the (B_1, B_2) plane for various A values, using parameters from Table I and different lags $(\xi = 0 \text{ s}, 0.15 \text{ s}, \text{ and } 0.2 \text{ s})$, see Fig. 5(b-g). Similar to Fig. 4(b), the safe region (green) in Fig. 5(b,d,f) is still triangular and it shrinks as the lag increases, ultimately vanishing at the same critical lag $\xi = 0.3$ s. Indeed, the safe domains for $B_2 = 0$ match those presented in Fig. 4(b). Furthermore, the safe domain moves towards higher A values as B_2 increases, signifying that enhanced response to the head CHV's speed makes a provably safe nominal CCC design more challenging. In Fig. 5(c,e,g), the safe region in the (B_1, B_2) plane shrinks to the "center" at $(\kappa_{\rm sf} - \xi \kappa_{\rm sf}^2, 0)$ as A decreases. The plant stable and head-to-tail string stable domains are also presented with red and blue shading, respectively. Similar to Fig. 4, the safe domains in Fig. 5 consistently reside within the plant and string stable region.

We remark that, in addition to CCC (5), a more general form of CCC could also be used, where the CAV not only responds to distance and speeds, but also to the HV's and CHV's accelerations [46]:

$$k_{\rm d}(x) = A \big(V(D_0) - v_0 \big) + B_1 \big(W(v_1) - v_0 \big) + \sum_{k \in \Phi} B_k \big(W(v_k) - v_0 \big) + C_1 a_1 + \sum_{k \in \Phi} C_k a_k.$$
 (52)

where C_1 and C_k are acceleration feedback gains.

Similar to Theorem 3, we derive the safety condition of CCC (52) by analyzing when condition (40) holds.

Theorem 4. System (4) with $u_0 = k_d(x)$ given by (52) and $A \ge 0$, $B_1 \ge 0$, $B_k \ge 0$, $\forall k \in \Phi$, is safe w.r.t. $S \cap S_e$ given by (27,37,43,45) if $v_0 \ge 0$, $|v_1 - v_0| \le \overline{v}$, $|v_k - v_0| \le \overline{v}$, $\forall k \in \Phi$ with some $\overline{v} > 0$, $a_1, a_k \in [-\overline{a}, \overline{a}]$, $\forall k \in \Phi$ with some $\overline{a} > 0$, $D_{st} > D_{sf}$, $\kappa_{sf} \ge \kappa, \gamma > 0$, and:

$$\frac{N_{1}\bar{v} + N_{2}\bar{a}}{\kappa(D_{\rm st} - D_{\rm sf})} \le A \le \frac{(1 - \xi\kappa_{\rm sf})^{2}}{4\xi} - \xi\left(\gamma - \frac{1 - \xi\kappa_{\rm sf}}{2\xi}\right)^{2},$$
(53)

where:

$$N_{1} = |\kappa_{\rm sf} - \xi \kappa_{\rm sf}^{2} - B_{1}| + \sum_{k \in \Phi} B_{k},$$

$$N_{2} = |\xi \kappa_{\rm sf} - C_{1}| + \sum_{k \in \Omega} |C_{k}|.$$
(54)

Please refer to the Appendix VI-D for the proof.

B. Safety-critical CCC

The safety charts in Fig. 4 and Fig. 5 help determine safe controller parameters for the nominal CCC (5). However, the safe region is relatively small compared to the string stable domain. Safe regions in Fig. 5(c,e,g) only cover low B_2 values, which prevent safe CCC from harnessing the benefits of connectivity, e.g., energy efficiency or high degree of string stability [33]. Furthermore, the safe domain even shrinks considerably as the lag increases, making it even impossible to achieve a safe nominal CCC design when $\xi > \xi_{cr}$. Therefore, tuning the existing CCC to always maintain safety is overly conservative and may lead to sub-optimal performance. To mitigate the trade-off between safety and performance, we propose the safety-critical CCC defined by (5,47,48). This approach enables us to optimize the gains of the nominal CCC (5) to achieve good performance, while the safety filter (47) activates when necessary to guarantee safety.

To evaluate the proposed controller, we first simulate a scenario where the CAV responds to the CHV two vehicles ahead (n = 1), as illustrated in Fig. 5(a). This simulation incorporates a lag of $\xi = 0.2$ s and tests various controllers:

- nominal CCC (6) with safe gains (point P in Fig. 5(g)),
- nominal CCC (6) with unsafe gains (point Q in Fig. 5(g)),

• safety-critical CCC (6,47,48) with unsafe gains (point Q). The results are shown in Fig. 6(a-d) by teal, blue and orange dashed curves, respectively, using parameters from Table I.

In Fig. 6, we consider an case where the CHV applies the brake with maximum deceleration, a_{\min} , and subsequently resumes its initial speed using maximum acceleration, a_{\max} , causing a speed perturbation denoted as v_{pert} . The behaviors expected from Fig. 5(f-g) are shown in panel (b). In all cases the CAV is plant and head-to-tail string stable, as its speed fluctuation is smaller than that of the CHV. In panels (c-d), the trajectory for safe gains P (teal) always stays inside the safe set, while the path for unsafe gains Q (blue) crosses the safety boundary and enters the unsafe region. Additionally, as stated by Corollary 1, the safety-critical CCC (6,47,48) successfully guarantees safety by slightly altering the unsafe nominal CCC only when the system is about to become unsafe (orange).

This minimal safety filter intervention is further demonstrated by Fig. 6(e-f), which presents the nominal CCC input (6) and safe controller input (48), denoted as $k_d(x)$ and $k_s(x)$, respectively. For safe gains P in panel (e), $k_s(x)$ remains consistently higher than $k_d(x)$, indicating that the nominal CCC $k_d(x)$ can ensure safety and the safety filter does not need to be activated. For unsafe gains Q in panel (f), the safetycritical controller k(x) remains the same as $k_d(x)$ when safe, while safety filter (47) intervenes when $k_d(x)$ exceeds $k_s(x)$ and alters the control input to $k_s(x)$ to ensure safety.

Fig. 6. (a-d) Simulations of system (1,4) for $\xi = 0.2$ s using the CCC (6) with n = 1 and with safe gains (teal) and unsafe gains (blue), and using the safety-critical CCC (6,47,48) with a safety filter (orange). Nominal and safe control inputs using (e) safe gains, and (f) unsafe gains with safety filter.

The safety filter is activated during acceleration rather than deceleration, see the orange dashed curve in Fig. 6(b) and the purple dashed curve in Fig. 6(f). This occurs since the CAV matches its velocity to the CHV. As the CHV decelerates, the CAV responds to it and brakes sooner than the HV, thereby increasing the distance between them and improving safety, see orange dashed curves in Fig. 6(a) and (d). However, when the CHV accelerates after braking, the CAV also begins to accelerate to match its velocity even when the preceding HV still drives at a lower speed, resulting in rapidly decreasing distance, see Fig. 6(a-b). Although this could cause a safety violation for the nominal CCC (blue), the safety filter engages at this point, mitigates the acceleration, and maintains a safe distance to the HV, see Fig. 6(f). Therefore, with the proposed safety-critical controller, connectivity can be leveraged to improve safety during deceleration while avoiding safety violations during acceleration.

To investigate the impact of the first-order lag ξ on the behavior of safety-critical CCC (6,47,48), we simulate same scenario depicted in Fig. 6. These simulations incorporate lags $\xi = 0$ s and $\xi = 1$ s in (4), see Fig. 7. We use the parameters in Table I and the unsafe gains Q with the safety filter.

In Fig. 7(a-b), when the CHV decelerates, the CAV with a higher lag (blue) responds later and requires more pronounced

Fig. 7. (a-d) Simulations of system (1,4) for lags $\xi = 0$ s (dark red) and $\xi = 1$ s (dashed blue) using the safety-critical CCC (6,47,48) with n = 1 and unsafe gains. Nominal and safe control inputs with (e) $\xi = 0$ s, and with (f) $\xi = 1$ s.

braking to maintain a safe distance, which results in a larger speed perturbation. However, when the CHV accelerates subsequent to braking, the CAV with a higher lag also accelerates later, and at the same time the HV also starts to increase its speed. Thus, the lag in acceleration enlarges the minimum distance between the CAV and HV, as shown in Fig. 7(a), thereby improving safety during acceleration and requiring less safety filter intervention, see Fig. 7(e-f). Importantly, the safety filter can always intervene and provide safety guarantees regardless of lags, as the trajectories always keep within the safe region in Fig. 7(c-d). Fig. 7(e-f) demonstrate the safety filter intervention by showing the nominal CCC input $k_{\rm d}(x)$ in (5) and safe controller input $k_{\rm s}(x)$ in (48) with CAV lag $\xi = 0$ s and $\xi = 1$ s, respectively. In both panels, the safety filter engages during CAV acceleration to mitigate the acceleration and keep safe distance. For the CAV with larger lag $\xi = 1$ s, it intervenes later and for a shorter period due to the CAV's later response to the CHV's acceleration.

To show the applicability of the proposed controller in the real world, we explore the multi-vehicle scenarios shown in Fig. 8(a) and Fig. 9(a), where the CAV is connected to a CHV two vehicles ahead (n = 1, $\Phi = 2$) and six vehicles ahead (n = 5, $\Phi = 6$). The speed profiles of the CHV and HVs are from real experimental data [7]. Fig. 8(b-c) and Fig. 9(b-c)

present the simulation results of CAVs with lag $\xi = 0.6$ s using nominal CCC (6) (blue) and safety-critical CCC (6,47,48) (orange), both with unsafe gains Q. Fig. 8(d) and Fig. 9(d) showcase the safety filter's engagement by visualizing the nominal, safe, and safety-critical control inputs, denoted as $k_d(x)$, $k_s(x)$, and k(x), respectively.

In Fig. 8 and Fig. 9, the safety-critical CCC successfully prevents the CAV from leaving the safe set as opposed to the nominal CCC, see panel (c). Similar to Fig. 6 and Fig. 7, the safety filter engages more frequently during CAV acceleration than deceleration, see panels (b) and (d) in Fig. 8 and Fig. 9. During deceleration, the CAV that is connected to a CHV farther ahead initiates braking earlier to synchronize with the CHV's speed, consequently increasing the distance and enhancing safety. This behavior results in the higher peak of $k_{\rm s}(x)$ in Fig. 9(d) compared to Fig. 8(d). During acceleration, the CAV that is connected to a CHV farther ahead also accelerates earlier while the preceding HV is still traveling at a lower speed, as shown by the gray line in the subplot of Fig. 9(b). This leads to a rapidly decreasing distance, necessitating more safety filter intervention to keep a safe distance, as indicated in the subplot of Fig. 9(b).

The prolonged safety filter interventions are also evident from the longer duration when $k_d(x) > k_s(x)$ in Fig. 9(d) compared to Fig. 8(d). Moreover, the behavior of $k_d(x)$ in Fig. 8(d) and Fig. 9(d) shows that connecting to a farther CHV results in smoother deceleration and harsher acceleration. However, the safety filter significantly mitigates the acceleration, thereby reducing the control effort required for the CAV, lowering energy consumption, and enhancing comfort, as seen in k(x). To summarize, connecting to a farther CHV substantially enhances safety during deceleration, and it may force the safety filter to intervene when ensuring safety during acceleration. Consequently, V2X connectivity, together with a safety-critical controller, significantly improves safety and reduces the control effort for the longitudinal control of CAVs.

VI. CONCLUSIONS

In this paper, we used control barrier function (CBF) theory to investigate the safety of connected automated vehicles (CAVs) implementing connected cruise control (CCC). In particular, we developed safety charts for existing CCC designs to provide safe controller parameters. We showed that the safe region in these charts shrinks due to the lag in the CAVs dynamics. The critical value of the lag for which safe regions disappear was also determined. By comparing safety and stability charts, we demonstrated that CAVs can achieve plant and head-to-tail string stability if they implement safe CCC parameters. Furthermore, we proposed safety-critical *CCC* to achieve high performance while guaranteeing safety despite the lag. We verified this controller via simulations using real traffic data, and highlighted that connectivity to vehicles farther ahead improves the safety of CAVs during deceleration, and it requires safety filter intervention during acceleration. In future research, we plan to investigate the nonlinear dynamics of safety-critical CCC.

Fig. 8. Simulation of a vehicle chain where a CAV (4) responds to the CHV two vehicles ahead with lag $\xi = 0.6$ s using the safety-critical CCC (6,47,48). The speed profiles of the CHV and the HVs are real experiment data.

Fig. 9. Simulation of a vehicle chain where a CAV (4) responds to the CHV six vehicles ahead with lag $\xi = 0.6$ s using the safety-critical CCC (6,47,48). The speed profiles of the CHV and the HVs speed are real experiment data.

APPENDIX

A. Expressions of Stability Boundaries

In this part, we provide the detailed calculations related to the stability analysis of Section III. We consider the case shown in Fig. 1, where a CAV follows the preceding HV while responding to the CHV that is n + 1 vehicles ahead using CCC (6). The resulting formulas (60,61,62) and (65,66,68,69) were used in Fig. 3, Fig. 4 and Fig. 5 to plot the plant stability (red) and head-to-tail string stability boundaries (blue), respectively.

For simplicity, we consider that each HV is identical, with $A_i = A_h$, $B_i = B_h$, $\kappa_i = \kappa_h$ and $V_i(.) = V_h(.)$ in (2,3) and $\mathbf{a}_i = \mathbf{a}_h$, $\mathbf{a}_{i\tau} = \mathbf{a}_{\tau}$, $\mathbf{b}_i = \mathbf{b}_h$ and $\mathbf{b}_{i\tau} = \mathbf{b}_{\tau}$ in (12) for $i \in \{1, ..., n\}$. Then, the coefficient matrices in (12) with $\Phi = \{n + 1\}$ are:

$$\mathbf{a}_{0} = \begin{bmatrix} 0 & -1 & 0\\ 0 & 0 & 1\\ \frac{A\kappa}{\xi} & -\frac{\Psi_{0}}{\xi} & -\frac{1}{\xi} \end{bmatrix}, \ \mathbf{b}_{0,1} = \begin{bmatrix} 1\\ 0\\ \frac{B_{1}}{\xi} \end{bmatrix}, \ \mathbf{b}_{0,n+1} = \begin{bmatrix} 0\\ 0\\ \frac{B_{n+1}}{\xi} \end{bmatrix}, \ \mathbf{a}_{h} = \begin{bmatrix} 0 & -1\\ 0 & 0 \end{bmatrix}, \ \mathbf{a}_{\tau} = \begin{bmatrix} 0 & 0\\ A_{h}\kappa & -\Psi_{h} \end{bmatrix}, \ \mathbf{b}_{h} = \begin{bmatrix} 1\\ 0 \end{bmatrix}, \ \mathbf{b}_{\tau} = \begin{bmatrix} 0\\ B_{h} \end{bmatrix},$$
(55)

with $\Psi_0 = A + B_1 + B_{n+1}$, $\Psi_h = A_h + B_h$. Substituting (55) into (14) leads to:

$$T_{0,1}(s) = \frac{B_1 s + A\kappa}{\xi s^3 + s^2 + \Psi_0 s + A\kappa},$$

$$T_{0,n+1}(s) = \frac{B_{n+1}s}{\xi s^3 + s^2 + \Psi_0 s + A\kappa},$$

$$T_{i,i+1}(s) = \frac{B_{h}s + A_{h}\kappa_{h}}{e^{s\tau}s^2 + \Psi_h s + A_{h}\kappa_{h}},$$

(56)

for $i \in \{1, ..., n\}$, and (17) becomes:

$$G_{0,n+1}(s) = T_{0,1}(s)T_{i,i+1}(s)^n + T_{0,n+1}(s).$$
 (57)

Since $D(T_{0,1}(s)) = D(T_{0,n+1}(s))$ given by (56), where D(.) denotes the denominator, the characteristic equation of the system is given by:

$$D(G_{0,n+1}(s)) = D(T_{0,1}(s))D(T_{i,i+1}(s))^n = 0.$$
 (58)

We assume that all HVs are plant stable, then $D(T_{i,i+1}(s)) = 0 \implies \text{Re}(s) < 0$, and the characteristic equation in (58) can be simplified to:

$$D(T_{0,1}(s)) = 0. (59)$$

Equation (19) gives plant stability boundary when s = 0. After substituting (56) and (59), it leads to:

$$A = 0. \tag{60}$$

The $s = \pm j\Omega$ plant stability boundary is obtained by (20). By substituting $T_{0,1}(j\Omega)$ from (56) and (59) into (20), we get the plant stability boundaries in the (A, B_1) space:

$$A = \frac{\Omega^2}{\kappa}, \quad B_1 = \left(\xi - \frac{1}{\kappa}\right)\Omega^2 - B_{n+1}, \tag{61}$$

or the boundaries in the (B_1, B_{n+1}) space:

$$B_{n+1} = A(\kappa\xi - 1) - B_1.$$
(62)

Equations (22) and (23) provide the $\omega = 0$ head-totail string stability boundary. After denoting the real and imaginary parts of the HVs' head-to-tail transfer function as $\Gamma_{\rm R}(\omega) = \operatorname{Re}(T_{i,i+1}(j\omega)^n)$, $\Gamma_{\rm I}(\omega) = \operatorname{Im}(T_{i,i+1}(j\omega)^n)$, and substituting (56) and (57) into (22), we have [39]:

$$P(\omega) = A^2 \kappa^2 \frac{1 - \Gamma_{\rm I}^2(\omega) - \Gamma_{\rm R}^2(\omega)}{\omega^2} - 2A\kappa \left(B_{n+1} \frac{\Gamma_{\rm I}(\omega)}{\omega} + 1 \right) + A(A + 2B_1 + 2B_{n+1}) + \mathcal{O}(\omega),$$
(63)

where $\mathcal{O}(\omega)$ denotes the higher order terms w.r.t. ω that vanish as $\omega \to 0$. Note that $\mathcal{O}(\omega)$ contains the terms of $1 - \Gamma_{\rm R}(\omega)$ and $\Gamma_{\rm I}(\omega)$ since $\lim_{\omega\to 0}\Gamma_{\rm R}(\omega) = 1$ and $\lim_{\omega\to 0}\Gamma_{\rm I}(\omega) = 0$ hold. Then, one can get the $\omega = 0$ head-to-tail string stability boundary via (23) by taking the limit $\omega \to 0$. According to L'Hôpital's rule, we have [40]:

$$\lim_{\omega \to 0} \frac{\Gamma_{\rm I}(\omega)}{\omega} = -\frac{n}{\kappa_{\rm h}}, \ \lim_{\omega \to 0} \frac{1 - \Gamma_{\rm I}^2(\omega) - \Gamma_{\rm R}^2(\omega)}{\omega^2} = L_{\rm h}, \ (64)$$

where $L_{\rm h} = n(A_{\rm h} + 2B_{\rm h} - 2\kappa_{\rm h})/(A_{\rm h}\kappa_{\rm h}^2)$ and *n* denotes the number of HVs. By substituting (63) and (64) into (23), we can derive $\omega = 0$ string stability boundary:

$$A = 0, \ A = -\frac{2\kappa_{\rm h}B_1 + (2n\kappa + 2\kappa_{\rm h})B_{n+1} - 2\kappa\kappa_{\rm h}}{\kappa_{\rm h}(L_{\rm h}\kappa^2 + 1)}, \ (65)$$

in the (A, B_1) space, and:

$$B_1 = -\frac{(L_h \kappa^2 + 1)}{2} A - \left(\frac{n\kappa}{\kappa_h} + 1\right) B_{n+1} + \kappa, \qquad (66)$$

in the (B_1, B_{n+1}) space.

Equation (24) defines the $\omega > 0$ head-to-tail string stability boundary, which can be rearranged into:

$$d_0(\omega) - n_0(\omega)\cos K + n_1(\omega)\sin K = 0,$$

$$d_1(\omega) - n_0(\omega)\sin K - n_1(\omega)\cos K = 0.$$
(67)

Substituting (56) and (57) into (24) and solving it for A, B_1 and B_{n+1} , we get the $\omega > 0$ head-to-tail string stability boundaries:

$$A = \frac{q_2 r_1 - q_1 r_2}{p_1 q_2 - p_2 q_1}, \quad B_1 = \frac{p_1 r_2 - p_2 r_1}{p_1 q_2 - p_2 q_1}, \tag{68}$$

in the (A, B_1) space, and:

$$B_1 = \frac{q_4 r_3 - q_3 r_4}{p_3 q_4 - p_4 q_3}, \quad B_{n+1} = \frac{p_3 r_4 - p_4 r_3}{p_3 q_4 - p_4 q_3}.$$
 (69)

in the (B_1, B_{n+1}) space, with coefficients:

$$p_{1} = \kappa(\Gamma_{\mathrm{R}}(\omega)\mathrm{cos}K - \Gamma_{\mathrm{I}}(\omega)\mathrm{sin}K - 1),$$

$$q_{1} = p_{3} = -\omega(\Gamma_{\mathrm{R}}(\omega)\mathrm{sin}K + \Gamma_{\mathrm{I}}(\omega)\mathrm{cos}K),$$

$$p_{2} = p_{4} = \kappa(\Gamma_{\mathrm{R}}(\omega)\mathrm{sin}K + \Gamma_{\mathrm{I}}(\omega)\mathrm{cos}K) - \omega,$$

$$q_{2} = \omega(\Gamma_{\mathrm{R}}(\omega)\mathrm{cos}K - \Gamma_{\mathrm{I}}(\omega)\mathrm{sin}K) - \omega,$$

$$r_{1} = \omega(B_{n+1}\mathrm{sin}K - \omega),$$

$$r_{2} = B_{n+1}\omega(1 - \mathrm{cos}K) - \omega^{3}\xi,$$

$$q_{3} = -\omega\mathrm{sin}K, \qquad q_{4} = \omega(\mathrm{cos}K - 1),$$

$$r_{3} = -p_{1}A - \omega^{2}, \qquad r_{4} = -p_{2}A - \omega^{3}\xi.$$
(70)

B. Proof of Theorem 3

Proof of Theorem 3. We prove safety via Corollary 2. For this, we prove that (40) holds. We express $k_s(x) - k_d(x)$ by substituting (48) and (5):

$$k_{\rm s}(x) - k_{\rm d}(x) = \xi \gamma \big(\kappa_{\rm sf}(v_1 - v_0) - a_0 \big) + (1 - \xi \kappa_{\rm sf}) a_0 + \xi \kappa_{\rm sf} a_1 + \xi \gamma_{\rm e} \big(\kappa_{\rm sf}(v_1 - v_0) - a_0 + \gamma (\kappa_{\rm sf}(D_0 - D_{\rm sf}) - v_0) \big) - A \big(V(D_0) - v_0 \big) - B_1 \big(W(v_1) - v_0 \big) - \sum_{k \in \Phi} B_k \big(W(v_k) - v_0 \big) . \big).$$
(71)

Based on (7,8), we use $V(D_0) \leq \kappa(D_0 - D_{st}), W(v_1) \leq v_1,$ $W(v_k) \leq v_k$. Furthermore, we consider $h_e(x) = 0, A \geq 0,$ $B_1 \geq 0, B_k \geq 0, \forall k \in \Phi$, which yields:

$$k_{\rm s}(x) - k_{\rm d}(x) \ge (\xi\gamma + \xi\kappa_{\rm sf} - 1) \big(\kappa_{\rm sf}(v_1 - v_0) - a_0\big) + \xi\kappa_{\rm sf}a_1 + \big(\kappa_{\rm sf}(1 - \xi\kappa_{\rm sf}) - B_1\big)(v_1 - v_0) - A\big(\kappa(D_0 - D_{\rm st}) - v_0\big) - \sum_{k \in \Phi} B_k\big(v_k - v_0\big).$$
(72)

Then we substitute $\kappa_{\rm sf}(v_1 - v_0) - a_0$ from $h_{\rm e}(x) = 0$, i.e., $\kappa_{\rm sf}(v_1 - v_0) - a_0 = -\gamma (\kappa_{\rm sf}(D_0 - D_{\rm sf}) - v_0)$, while we add and subtract Ah(x) on the right-hand side, which leads to:

$$k_{\rm s}(x) - k_{\rm d}(x) \ge A(\kappa_{\rm sf} - \kappa)(D_0 - D_{\rm sf}) + A\kappa(D_{\rm st} - D_{\rm sf}) - (\xi\gamma^2 + \xi\kappa_{\rm sf}\gamma - \gamma + A)(\kappa_{\rm sf}(D_0 - D_{\rm sf}) - v_0) + \xi\kappa_{\rm sf}a_1$$

+
$$(\kappa_{\rm sf} - \xi \kappa_{\rm sf}^2 - B_1)(v_1 - v_0) - \sum_{k \in \Phi} B_k (v_k - v_0).$$
 (73)

Since $h(x) = \kappa_{sf}(D_0 - D_{sf}) - v_0 \ge 0$ is considered in (40), the third term on the right-hand side is nonnegative if:

$$\xi \gamma^2 + \xi \kappa_{\rm sf} \gamma - \gamma + A =$$

= $\xi \left(\gamma - \frac{1 - \xi \kappa_{\rm sf}}{2\xi} \right)^2 + A - \frac{(1 - \xi \kappa_{\rm sf})^2}{4\xi} \le 0, \quad (74)$

which holds given the upper bound on A in (49). Then we have:

$$k_{\rm s}(x) - k_{\rm d}(x) \ge A(\kappa_{\rm sf} - \kappa)(D_0 - D_{\rm sf}) + A\kappa(D_{\rm st} - D_{\rm sf}) + \xi\kappa_{\rm sf}a_1 - |\kappa_{\rm sf} - \xi\kappa_{\rm sf}^2 - B_1||v_1 - v_0| - \sum_{k \in \Phi} B_k|v_k - v_0|,$$
(75)

where $D_0 - D_{sf} \ge 0$ since $h(x) \ge 0$ and $v_0 \ge 0$. Finally, considering $|v_1 - v_0| \le \overline{v}$, $|v_k - v_0| \le \overline{v}$, $\forall k \in \Phi$, $a_1 \ge -a_{\min}$, $\kappa_{sf} \ge \kappa$, (73) leads to:

$$k_{\rm s}(x) - k_{\rm d}(x) \ge A\kappa(D_{\rm st} - D_{\rm sf}) - \left(\left| \kappa_{\rm sf} - \xi\kappa_{\rm sf}^2 - B_1 \right| + \sum_{k \in \Phi} B_k \right) \bar{v} - \xi\kappa_{\rm sf} a_{\rm min} \ge 0.$$
(76)

Considering the lower bound on A in (49) and $D_{st} > D_{sf}$, (76) implies that (40) holds. Therefore, Corollary 2 provides safety and completes the proof.

C. Proof of Corollary 3

Proof of Corollary 3. Based on (49) with $\gamma = (1 - \xi \kappa_{sf})/(2\xi)$ and $\xi < 1/\kappa_{sf}$, safe control gains exist only when:

$$\frac{(1-\xi\kappa_{\rm sf})^2}{4\xi} \ge \frac{\xi\kappa_{\rm sf}a_{\rm min}}{\kappa(D_{\rm st}-D_{\rm sf})}.$$
(77)

Consider:

$$\rho = \sqrt{\frac{4\kappa_{\rm sf}a_{\rm min}}{\kappa(D_{\rm st} - D_{\rm sf})}},\tag{78}$$

(71) (77) leads to:

$$(1 - \xi \kappa_{\rm sf} + \xi \rho)(1 - \xi \kappa_{\rm sf} - \xi \rho) \ge 0$$
(79)

If $\kappa_{\rm sf} = \rho$, (79) leads to:

$$\xi \le \frac{1}{2\kappa_{\rm sf}} = \frac{1}{\kappa_{\rm sf} + \rho}.\tag{80}$$

If $\kappa_{\rm sf} > \rho$, solving (79) yields:

$$\xi \le \frac{1}{\kappa_{\rm sf} + \rho} \quad \text{or} \quad \xi \ge \frac{1}{\kappa_{\rm sf} - \rho}.$$
 (81)

Since $\xi < 1/\kappa_{sf}$, only the former case in (81) holds. If $\kappa_{sf} < \rho$, (79) gives:

$$\frac{1}{\kappa_{\rm sf} - \rho} \le \xi \le \frac{1}{\kappa_{\rm sf} + \rho}.$$
(82)

Since $\xi > 0$ in Theorem 3, only the upper bound of the ξ in (82) holds. Therefore, $\xi \leq \xi_{cr} = 1/(\kappa_{sf} + \rho)$ holds for all cases, as given by (50).

D. Proof of Theorem 4

Proof of Theorem 4. Similar to the proof of Theorem 3, we prove safety by showing that (40) holds, where

$$k_{\rm s}(x) - k_{\rm d}(x) = \xi \gamma \left(\kappa_{\rm sf}(v_1 - v_0) - a_0 \right) + (1 - \xi \kappa_{\rm sf}) a_0 + \xi \gamma_{\rm e} \left(\kappa_{\rm sf}(v_1 - v_0) - a_0 + \gamma (\kappa_{\rm sf}(D_0 - D_{\rm sf}) - v_0) \right) + (\xi \kappa_{\rm sf} - C_1) a_1 - A \left(V(D_0) - v_0 \right) - B_1 \left(W(v_1) - v_0 \right) - \sum_{k \in \Phi} B_k \left(W(v_k) - v_0 \right) - \sum_{k \in \Phi} C_k a_k.$$
(83)

By following the steps in (72)-(75), the following inequality can be derived:

$$k_{\rm s}(x) - k_{\rm d}(x) \ge A(\kappa_{\rm sf} - \kappa)(D_0 - D_{\rm sf}) + A\kappa(D_{\rm st} - D_{\rm sf}) + (\xi\kappa_{\rm sf} - C_1)a_1 - |\kappa_{\rm sf} - \xi\kappa_{\rm sf}^2 - B_1||v_1 - v_0| - \sum_{k \in \Phi} B_k|v_k - v_0| - \sum_{k \in \Phi} C_k a_k,$$
(84)

where the additional acceleration feedback terms show up compared to (75). Then, considering $a_1, a_k \in [-\bar{a}, \bar{a}], \forall k \in \Phi$, we obtain:

$$k_{\rm s}(x) - k_{\rm d}(x) \ge A\kappa(D_{\rm st} - D_{\rm sf}) - \left(\left| \kappa_{\rm sf} - \xi \kappa_{\rm sf}^2 - B_1 \right| + \sum_{k \in \Phi} B_k \right) \bar{v} - \left(\left| \xi \kappa_{\rm sf} - C_1 \right| + \sum_{k \in \Phi} |C_k| \right) \bar{a},$$

$$(85)$$

cf. (75). Using the lower bound on A in (53) and $D_{\rm st} > D_{\rm sf}$, we obtain that (40) holds and Corollary 2 implies safety. \Box

Yuchen Chen received the BSc degree in Mechanical Engineering from South China University of Technology, China, in 2022 and the MSc degree from the University of Michigan, USA, in 2024. He is currently pursuing the PhD degree in mechanical engineering with the University of Michigan, Ann Arbor, USA. His current research interests include control of connected autonomous vehicles, safetycritical control, and vehicle dynamics.

Tamas G. Molnar is an Assistant Professor of Mechanical Engineering at the Wichita State University since 2023. Beforehand, he held postdoctoral positions at the California Institute of Technology, from 2020 to 2023, and at the University of Michigan, Ann Arbor, from 2018 to 2020. He received his PhD and MSc in Mechanical Engineering and his BSc in Mechatronics Engineering from the Budapest University of Technology and Economics, Hungary, in 2018, 2015, and 2013. His research interests include nonlinear dynamics and control, safety-critical

control, and time delay systems with applications to connected automated vehicles, robotic systems, and autonomous systems.

Gábor Orosz received the MSc degree in Engineering Physics from the Budapest University of Technology, Hungary, in 2002 and the PhD degree in Engineering Mathematics from the University of Bristol, UK, in 2006. He held postdoctoral positions at the University of Exeter, UK, and at the University of California, Santa Barbara. In 2010, he joined the University of Michigan, Ann Arbor where he is currently a Professor in Mechanical Engineering and in Civil and Environmental Engineering. From 2017 to 2018 he was a Visiting Professor in Control

and Dynamical Systems at the California Institute of Technology. In 2022 he was a Distinguished Guest Researcher in Applied Mechanics at the Budapest University of Technology and from 2023 to 2024 he was a Fulbright Scholar at the same institution. His research interests include nonlinear dynamics and control, time delay systems, machine learning, and data-driven systems with applications to connected and automated vehicles, traffic flow, and biological networks.
