Nonasymptotic Analysis of Classical Spectrum Estimators with L-mixing Time-series Data

Yuping Zheng and Andrew Lamperski

Abstract-Spectral estimation is a fundamental problem for time series analysis, which is widely applied in economics, speech analysis, seismology, and control systems. The asymptotic convergence theory for classical, non-parametric estimators, is well-understood, but the non-asymptotic theory is still rather limited. Our recent work gave the first non-asymptotic error bounds on the well-known Bartlett and Welch methods, but under restrictive assumptions. In this paper, we derive non-asymptotic error bounds for a class of non-parametric spectral estimators, which includes the classical Bartlett and Welch methods, under the assumption that the data is an Lmixing stochastic process. A broad range of processes arising in time-series analysis, such as autoregressive processes and measurements of geometrically ergodic Markov chains, can be shown to be L-mixing. In particular, L-mixing processes can model a variety of nonlinear phenomena which do not satisfy the assumptions of our prior work. Our new error bounds for L-mixing processes match the error bounds in the restrictive settings from prior work up to logarithmic factors.

I. INTRODUCTION

Spectral estimation is the problem of estimating the power spectral density of a time series from a finite record of data samples. It is widely applied in economics, speech analysis, seismology, control systems and more. The most common spectral estimation approaches are non-parametric (classical) methods and parametric (modern) methods [1]. Common non-parametric methods include periodograms, the Welch method, the Bartlett method, and the Blackman-Tukey method. Common parametric forms include ARMA and state space models. Non-parametric estimators are widely used in practice, especially when information required to select a parametric model, such as autoregressive order, is unknown. In this work, we focus on the analysis of two classical spectrum estimators: Bartlett and Welch estimators.

The asymptotic analysis of spectral estimators, in which the length of the time series goes to infinity, is wellunderstood [1], [2], [3], [4]. In practice, only a finite amount of data is available, and so non-asymptotic error bounds are desirable. For parametric estimation, non-asymptotic results have been long available for autoregressive models [5], while the non-asymptotic analysis of linear state-space models has become reasonably mature [6]–[10].

The non-asymptotic theory of non-parametric spectral estimation is substantially less developed than either the asymptotic theory of non-parametric methods, or the nonasymptotic theory of parametric time series estimators. The most closely related work is [11], which gives nonasymptotic error bounds of Bartlett, Welch, and Blackman-Tukey estimators, albeit under restrictive assumptions. Nonasymptotic bounds for estimators not covered in this paper include work on Blackman-Tukey methods [12], [13], smoothed periodograms [14], and Wiener filters [15].

Our contribution is to obtain non-asymptotic error bounds for Bartlett and Welch estimators under the condition that the data series is L-mixing. The class of L-mixing processes was introduced in [16] to quantify the decay of dependencies of stochastic processes over time. Many common models in time series analysis can be proved to be L-mixing, like autoregressive processes [16] and measurements of uniformly geometrically ergodic Markov chains [17]. In recent years, the theory of L-mixing processes has been used to give non-asymptotic error bounds on stochastic optimization methods with temporally dependent data streams [18], [19]. In Subsection II-D, we give a detailed comparison between the *L*-mixing assumption and the assumptions from [11]. In particular, we explain how L-mixing processes cover a variety of nonlinear phenomena (both in the dynamics and the measurements), which do not satisfy the assumptions in [11], while in many cases (and arguably, most practical cases), data sequences satisfying the assumptions in [11] are also L-mixing.

The paper is organized as follows. In Section II, we set up the problem and present the algorithm. Section III presents the main results on spectral estimation error analysis. In Section IV, we describe background on *L*-mixing processes need in the main proofs. Then, Section V gives proofs of the main results. Section VI verifies our theory with a simulation of a finite-state Markov chain. Conclusions are given in Section VII.

II. PROBLEM SETUP

A. Notation

The sets of real numbers, complex numbers and nonnegative integers are denoted by \mathbb{R} , \mathbb{C} and \mathbb{N} respectively. Random variables are denoted in bold. If **x** is a random variable, then $\mathbb{E}[\mathbf{x}]$ is its expected value. $||\mathbf{x}||_2$ denotes the Euclidean norm of the vector x. For matrix A, $||A||_2$ denotes the spectral norm and $||A||_F$ denotes the Frobenius norm. \mathbf{y}^* denotes the conjugate transpose of \mathbf{y} . Let j denote the imaginary unit. For real numbers a and b, denote $a \lor b = \max\{a, b\}$.

Let \mathcal{Y} be a finite-dimensional vector space with inner product $\langle \cdot, \cdot \rangle$ and corresponding norm $\|\cdot\|$. For a random variable, $\mathbf{y} \in \mathcal{Y}$, and $q \geq 1$ let $\|\mathbf{y}\|_{L_q} = (\mathbb{E}[\|\mathbf{y}\|^q])^{1/q}$, which is the corresponding L_q norm.

B. L-mixing processes

We will assume that the data, $\mathbf{v}[k]$, is an *L*-mixing process. Here, we introduce some background for L-mixing processes. We start with the classical definitions in continuous time and describe how they change for discrete time.

Let $\mathcal{F} = (\mathcal{F}_t)_{t>0}$ be an increasing family of σ -algebras. Let $\mathcal{F}^+ = (\mathcal{F}^+_t)_{t>0}$ be a decreasing family of σ -algebras such that for all $t \ge 0$, \mathcal{F}_t and \mathcal{F}_t^+ are independent, $\mathcal{F}_t^+ = \mathcal{F}_0^+$ for all $t \le 0$, and $\mathcal{F}_t^+ = \sigma \{\bigcup_{\epsilon > 0} \mathcal{F}_{t+\epsilon}\}$. A continuous-time stochastic process $\mathbf{y}_t \in \mathcal{Y}$ is called *L-mixing* with respect to $(\mathcal{F}, \mathcal{F}^+)$ if

- \mathbf{y}_t is measurable with respect to \mathcal{F}_t for all $t \ge 0$
- $M_q(\mathbf{y}) := \sup_{t \ge 0} \|\mathbf{y}_t\|_{L_q} < \infty$ for all $q \ge 1$ $\Gamma_q(\mathbf{y}) := \int_0^\infty \gamma_q(\tau, \mathbf{y}) d\tau < \infty$ for all $q \ge 1$, where $\gamma_q(\tau, \mathbf{y}) = \sup_{t \ge \tau} \|\mathbf{y}_t - \mathbb{E}[\mathbf{y}_t | \mathcal{F}_{t-\tau}^+]\|_{L_q}.$

The number, $\Gamma_q(\mathbf{y})$ characterizes the speed at which dependencies decay over time.

Now we sketch the discrete-time case. Let $\mathcal{F} = (\mathcal{F}_k)_{k\geq 0}$ be an increasing sequence of σ -algebras and let \mathcal{F}^+ = $(\mathcal{F}_k^+)_{k>0}$ be a decreasing sequence of σ -algebras such that \mathcal{F}_k and \mathcal{F}_k^+ are independent for all $k \geq 0$. We say that the discrete-time process \mathbf{y}_k is L-mixing with respect to $(\mathcal{F}, \mathcal{F}^+)$, if the continuous-time process defined by $\mathbf{y}_t =$ $\mathbf{y}_{\lfloor t \rfloor}$ is L-mixing with respect to the continuous-time σ algebras defined by $\mathcal{F}_t = \mathcal{F}_{\lfloor t \rfloor}$ and $\mathcal{F}_t^+ = \mathcal{F}_{\lfloor t \rfloor}^+$. The moment bounds remains the same as in continuous

time, but the discrete-time counterpart of $\Gamma_q(\mathbf{y})$ is defined by

$$\Gamma_{d,q}(\mathbf{y}) = \sum_{k=0}^{\infty} \gamma_q(k, \mathbf{y}).$$

See Subsection IV-B for more details.

C. Problem and Algorithm

Given a stationary zero-mean discrete-time stochastic process $\mathbf{y}[k] \in \mathbb{R}^n$, the autocovariance sequence and power sepctral density are

$$R[k] = \mathbb{E}[\mathbf{y}[i+k]\mathbf{y}[i]^{\top}]$$
$$\Phi(s) = \sum_{-\infty}^{\infty} e^{-j2\pi sk} R[k]$$

where $s \in [-1/2, 1/2]$.

We focus on the analysis of two non-parametric spectrum estimators, the Bartlett and Welch methods.

The Bartlett and Welch estimators can be expressed in batch form as:

$$\hat{\mathbf{y}}_i(s) = \sum_{k=0}^{M-1} w_k(s) \mathbf{y}[iK+k]$$
$$\hat{\mathbf{\Phi}}_L(s) = \frac{1}{L} \sum_{i=0}^{L-1} \hat{\mathbf{y}}_i(s) \hat{\mathbf{y}}_i(s)^{\star}$$

where the Bartlett method has K = M and $w_k(s) =$ $\frac{1}{\sqrt{M}}e^{-j2\pi ks}$, while the Welch method may have $K \neq M$ and uses $w_k(s) = \frac{v_k}{\|v\|_2} e^{-j2\pi ks}$ for some window vector $0 \neq v \in \mathbb{R}^M$.

In both the Bartlett and Welch estimators, w(s) is a Euclidean unit vector for all s: $\sum_{k=0}^{M-1} |w_k(s)|^2 = 1$.

Let $\mathbf{x}_k = \hat{\mathbf{\Phi}}_k(s)$ and $\mathbf{z}_k = \overline{\hat{\mathbf{y}}_k(s)}\hat{\mathbf{y}}_k(s)^*$. We have the general expression of the two estimators:

$$\mathbf{x}_k = \frac{1}{k} \sum_{i=0}^{k-1} \mathbf{z}_i.$$

When k = 0, we can simply set $\mathbf{x}_0 = 0$.

The general algorithm can also be expressed in iterative form as:

$$\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha_k (\mathbf{z}_k - \mathbf{x}_k)$$

where $\alpha_k = \frac{1}{k+1}$.

D. Comparison with Assumptions from [11]

In this paper, we assume that y[k] is an L-mixing sequence. In contrast, the work in [11] requires that at least one of following two assumptions hold:

- A1) $\mathbf{y}[k]$ is Gaussian
- A2) There is an impulse response sequence $h[k] \in \mathbb{R}^{n \times m}$ such that $\mathbf{y}[k] = \sum_{\ell = -\infty}^{\infty} h[k - \ell] \boldsymbol{\zeta}[\ell]$, where $\boldsymbol{\zeta}[k] =$ $\begin{bmatrix} \boldsymbol{\zeta}_1[k] & \cdots & \boldsymbol{\zeta}_m[k] \end{bmatrix}^{\top}$ such that for $i = 1, \dots, m$ and for $k \in \mathbb{Z}$, $\zeta_i[k]$ are independent σ -sub-Gaussian random variables.

As we will discuss below, the class of L-mixing processes contains a wide variety of processes that cannot be modeled by the assumptions from [11]. While there may be some processes that satisfy the assumptions of [11], we will see that in many cases, the processes satisfying the assumptions from [11] are also *L*-mixing.

The class of L-mixing processes includes measurements of geometrically ergodic Markov chains, [17], which can be used to model a wide variety of stable nonlinear stochastic systems.¹ In particular, measurements of an ergodic Markov chain on a finite state space are L-mixing, but do not fit the assumptions from [11].

Furthermore, the class of *L*-mixing processes is closed under a variety of operations. In particular, if $\zeta[k]$ is Lmixing, passing $\boldsymbol{\zeta}[k]$ through a stable, causal linear filter results in another L-mixing sequence. (Specific conditions on the filter are discussed in the result below.) If f is Lipschitz, then $f(\boldsymbol{\zeta}[k])$ is L-mixing. The product of two L-mixing sequences is also L-mixing. As a result, rather complex processes can be shown to be *L*-mixing.

The next result shows under suitable hypotheses on the filter h, data satisfying assumption A2 are also L-mixing. It is proved in Subsection V-D.

¹The work in [17] only proves the L-mixing property for measurements of uniformly geometrically ergodic Markov chains satisfying a 1-step Doeblin condition. Based on our ongoing work, we hypothesize that measurements of irreducible, V-uniformly ergodic Markov chains are also L-mixing. The class of irreducible, V-uniformly ergodic Markov chains is broad, and covers nonlinear stochastic dynamical systems which satisfy a stochastic Lyapunov stability condition. See [20], [21].

Proposition 1: If $\mathbf{y}[k]$ satisfies A2 and h is causal with $\sum_{\ell=0}^{\infty} \|h[\ell]\|_2(\ell+1) < \infty$, then $\mathbf{y}[k]$ is L-mixing with

$$M_{q}(\mathbf{y}) \leq 8m\sigma\sqrt{q} \sum_{\ell=0}^{\infty} \|h[\ell]\|_{2}$$

$$\Gamma_{d,q}(\mathbf{y}) \leq 8m\sigma\sqrt{q} \sum_{\ell=0}^{\infty} \|h[\ell]\|_{2}(\ell+1)$$

Remark 1: In the case that $\mathbf{y}[k]$ is Gaussian, under the conditions that $\Phi(s)$ admits a spectral factorization (see [22]), $\mathbf{y}[k]$ also satisfies A2 with a causal filter h, m = n, and $\boldsymbol{\zeta}[k]$ Gaussian. In particular, when $\mathbf{y}[k]$ is generated by a stable linear Gaussian state space system, h can be computed from the Kalman filter, and the hypotheses of Proposition 1 hold. However, finding more general conditions to ensure that h satisfies the requirements of Proposition 1 is out of the scope of this paper.

III. MAIN RESULTS OF CONVERGENCE ANALYSIS

We conduct the convergence analysis of the proposed algorithm which generalizes the two classical spectrum estimators. The main results show both the variance and bias bound of the estimators.

Let $\bar{z} = \mathbb{E}[\mathbf{z}_k] = \mathbb{E}[\mathbf{\Phi}_k(s)]$. The following result bounds the averaged deviation between the algorithm and its mean value.

Theorem 1: Let $\mathbf{y}[k]$ be an L-mixing sequence. Assume that $\mathbf{x}_0 = 0$, $\alpha_j = \frac{1}{j+1}$, $\forall j \in \mathbb{N}$ and $j \in [0, k-1]$, then for all integers $k \ge 4$ and all $q \ge 1$:

$$\|\hat{\Phi}_k(s) - \bar{z}\|_{L_q} \le b_q \frac{1}{\sqrt{k}} \log_2(\log_2 k)$$

where

$$b_q = 128(4q-1)\sqrt{3(2q-1)}M_{4q}(\mathbf{y})\Gamma_{d,4q}(\mathbf{y}) \cdot \left(4\frac{M}{K}\sqrt{2(4q-1)}M_{4q}(\mathbf{y})\Gamma_{d,4q}(\mathbf{y}) + 2\Gamma_{d,4q}(\mathbf{y})\right)^{1/2} + 8(4q-1)M_{4q}(\mathbf{y})\Gamma_{d,4q}(\mathbf{y}).$$
Note that for Partlett estimator $M = K$

Note that for Bartlett estimator M = K.

The result of Theorem 1 holds in expectation. When the factor in the bound, b_q , grows polynomially with qTheorem 1 implies a bound that holds in high probability. In the Markov chain example from Section VI, and also in the processes satisfying the hypotheses of Proposition 1, the polynomial growth assumption holds, and so the bounds can be computed explicitly.

Theorem 2: If there are constants c > 0 and r > 0 such that b_q from Theorem 1 satisfies $b_q \leq cq^r$ for all $q \geq 1$, then for all $\nu \in (0,1)$ and all $k \ge 4$:

$$\mathbb{P}\left(\|\hat{\Phi}_{k}(s) - \mathbb{E}[\hat{\Phi}_{k}(s)]\|_{F} > \frac{c \log_{2}(\log_{2}(k))}{\sqrt{k}} e^{r} \max\left\{1, \frac{(\ln \nu^{-1})^{r}}{r^{r}}\right\}\right) \leq \nu.$$

The following result is an immediate consequence of Proposition 1 and Theorem 2. It enables direct comparison with the results from [11] in the case when the data can also be shown to be *L*-mixing.

Corollary 1: If $\mathbf{y}[k]$ satisfies A2 and h is causal with $\sum_{\ell=0}^{\infty} \|h[\ell]\|_2(\ell+1) < \infty$, then there are constants c > 0and r > 0 such that $b_q \leq cq^r$ for all $q \geq 1$. Consequently, the bound from Theorem 2 holds.

Remark 2: The estimate, $\hat{\Phi}_k(s)$ depends on the data $\mathbf{y}[0], \ldots, \mathbf{y}[(k-1)K + (M-1)]$. In other words, the total amount of data is N = (k - 1)K + (M - 1). In the typical setup of Bartlett or Welch methods, $K \leq M$, so that $k \leq \frac{N}{K}$. It follows that, in terms of the total amount of data, the bound from Theorem 2 is $O\left(\frac{\log_2(\log_2(N/K))}{\sqrt{N/K}}\right)$, which matches the corresponding bound from [11] up to logarithmic factors.

The spectral estimators are biased, meaning that $\Phi(s) \neq 0$ $\mathbb{E}[\Phi_k(s)]$. So, full error bounds must also include bounds on the bias. In the case of L-mixing data, these bounds can be computed in terms of the mixing properties and parameters of the algorithms.

Proposition 2: If $\mathbf{y}[k]$ is L-mixing then:

• The bias of the Bartlett estimator is bounded by

$$\begin{split} \|\Phi(s) - \mathbb{E}[\hat{\Phi}_k(s)]\|_2 &\leq 2M_q(\mathbf{y}) \sum_{|k| \geq M} \gamma_2(|k|, \mathbf{y}) + \\ &\frac{2M_q(\mathbf{y})}{M} \sum_{|k| \leq M} |k|\gamma_2(|k|, \mathbf{y}). \end{split}$$

• The bias of the Welch estimator is bounded by:

$$\begin{split} \|\Phi(s) - \mathbb{E}[\hat{\Phi}_k(s)]\|_2 &\leq 2M_q(\mathbf{y}) \sum_{|k| \geq M} \gamma_2(|k|, \mathbf{y}) + \\ & 2M_q(\mathbf{y}) \sum_{|k| < M} \gamma_2(|k|, \mathbf{y}) \sum_{i=|k|}^{M-1} \frac{v_{i-|k|}v_i}{\|v\|_2^2}. \end{split}$$

The current bias bounds depend on the mixing properties in a rather complicated way. More explicit bounds, similar to those sketched in [11] could be obtained, in particular, when $\gamma_2(k, \mathbf{y})$ decreases exponentially. However, the corresponding formulas are outside the scope of this work.

IV. L-MIXING PROPERTIES

This section describes the main results on L-mixing processes needed to prove Theorem 1. We first extend some results on scalar-valued *L*-mixing processes derived in [16] to processes defined on an arbitrary finite-dimensional inner product space. This vector extension enables cleaner proofs than reduction of vector/matrix problems to the original scalar case. After presenting the general results, we use them to relate the L-mixing properties of the data sequences y[k], to the corresponding matrices used in spectral estimation, $\hat{\mathbf{y}}_k(s)\hat{\mathbf{y}}_k(s)^{\star}$.

A. Variations on Classical L-mixing Results

We present extensions of classical L-mixing results to the case of stochastic processes taking values in an arbitrary finite-dimensional inner product space. The proof methods largely follow those in [16]. So rather than proving the results, we will just sketch where they deviate.

The following generalizes Lemma 2.3 of [16].

Lemma 1: If $\mathbf{y}_t \in \mathcal{Y}$ is a zero-mean L-mixing process with respect to $(\mathcal{F}, \mathcal{F}^+)$ and $\mathbf{z} \in \mathcal{Y}$ is \mathcal{F}_s -measurable with $s \leq t$, then for any $p \geq 1$ and $q \geq 1$ with $\frac{1}{p} + \frac{1}{q}$, we have

$$\left|\mathbb{E}\left[\langle \mathbf{y}_t, \mathbf{z} \rangle\right]\right| \le 2\gamma_p(t-s, \mathbf{y}) \|\mathbf{z}\|_{L_q}.$$

Proof: [Sketch] Follow the same steps as the proof in [16], but replace multiplication with an inner product.

The following result generalizes Theorem 1.1 of [16] to vector-valued \mathbf{u}_t and complex-valued f_t .

Lemma 2: Let $\mathbf{u}_t \in \mathcal{Y}$ be a zero-mean L-mixing process and let $f_t \in \mathbb{C}$. For all $m \ge 1$ and all $T \ge 0$:

$$\begin{split} \left\| \int_0^T f_t \mathbf{u}_t dt \right\|_{L_{2m}} &\leq \\ & 2\sqrt{(2m-1)M_{2m}(\mathbf{u})\Gamma_{2m}(\mathbf{u})} \sqrt{\int_0^T |f_t|^2 dt}. \end{split}$$

Proof: [Sketch] Let $\mathbf{x}_t = \int_0^t f_s \mathbf{u}_s ds$. The main difference from the proof [16] is that we get different expressions for the required derivatives of \mathbf{x}_t :

$$\frac{d}{dt} \|\mathbf{x}_t\|^{2m} = 2m \|\mathbf{x}_t\|^{2(m-1)} \operatorname{Re}\langle \mathbf{x}_t, f_t \mathbf{u}_t \rangle$$
$$\frac{d}{dt} \left(\|\mathbf{x}_t\|^{2(m-1)} \mathbf{x}_t \right) = \|\mathbf{x}_t\|^{2(m-1)} \alpha_t \mathbf{u}_t + (m-1) \|\mathbf{x}_t\|^{2(m-2)} \left(\langle \mathbf{x}_t, f_t \mathbf{u}_t \rangle + \langle f_t \mathbf{u}_t, \mathbf{x}_t \rangle \right) \mathbf{x}_t$$

After upper-bounding (via Lemma 1) the same bound derived in Equation (2.9) of [16] holds in this more general case. The proof is identical after that.

B. Discussion on Discrete-Time L-mixing Processes

All results in continuous-time extend to discrete-time by appropriately embedding the stochastic process and σ algebras into continuous time.

If $\mathbf{y}_k \in \mathcal{Y}$ is a discrete-time stochastic process, we can always extend it to continuous-time stochastic process by setting $\mathbf{y}_t = \mathbf{y}_{\lfloor t \rfloor}$ for all $t \ge 0$. Similarly, say that \mathcal{F}_k defines an increasing family of σ -algebras and \mathcal{F}_k^+ defines a decreasing family of σ -algebras such that \mathcal{F}_k and \mathcal{F}_k^+ are independent for all $k \in \mathbb{N}$. Then $\mathcal{F}_t = \mathcal{F}_{\lfloor t \rfloor}$ and $\mathcal{F}_t^+ = \mathcal{F}_{\lfloor t \rfloor}^+$ define respectively increasing and decreasing families of σ algebras such that \mathcal{F}_t and \mathcal{F}_t^+ are independent for all $t \ge 0$. Furthermore, it can be shown that $\mathcal{F}_t^+ = \sigma \{\bigcup_{\epsilon>0} \mathcal{F}_{t+\epsilon}^+\}$ for all $t \ge 0$. Then, we can obtain the definition of discrete-time *L*-mixing process in Section II-B.

Note that some floor function arithmetic shows that $\gamma_q(\tau, \mathbf{y}) = \max\{\gamma_q(\lfloor \tau \rfloor, \mathbf{y}), \gamma_q(\lfloor \tau \rfloor + 1, \mathbf{y})\}$, which implies that

$$\Gamma_{d,q}(\mathbf{y}) \leq \Gamma_q(\mathbf{y}) \leq 2\Gamma_{d,q}(\mathbf{y}).$$

In particular, $\Gamma_{d,q}(\mathbf{y})$ is finite if and only if $\Gamma_q(\mathbf{y})$ is finite. The next result follows from Lemma 2 applied to $\mathbf{y}_t =$

 $\mathbf{y}_{\lfloor t \rfloor}$ and $w_t = w_{\lfloor t \rfloor}$, and then using the bounds on $\Gamma_{d,q}(\mathbf{y})$.

Corollary 2: Let $\mathbf{y}_k \in \mathcal{Y}$ be a zero-mean L-mixing discrete-time process and let $w_k \in \mathbb{C}$. For all $M \geq 1$ and

all $q \ge 1$:

$$\left\|\sum_{k=0}^{M-1} w_k \mathbf{y}_k\right\|_{L_{2q}} \leq 2\sqrt{2(2q-1)M_{2q}(\mathbf{y})\Gamma_{d,2q}(\mathbf{y})} \sqrt{\sum_{k=0}^{M-1} |w_k|^2}$$

C. L-mixing properties of Spectral Data Matrices

The following result shows that the data matrices, $\hat{\mathbf{y}}_i(s)\hat{\mathbf{y}}_i(s)^*$ inherit *L*-mixing properties from the original data sequence, $\mathbf{y}[k]$:

Proposition 3: If $\mathbf{y}[k]$ (using the Euclidean norm) is *L*mixing with respect to $(\mathcal{F}, \mathcal{F}^+)$, then for all $s \in \mathbb{R}$, $\hat{\mathbf{y}}_i(s)\hat{\mathbf{y}}_i(s)^*$ (using the Frobenius norm) is *L*-mixing with respect to $(\mathcal{G}, \mathcal{G}^+)$ where $\mathcal{G}_i = \mathcal{F}_{iK+(M-1)}$ and $\mathcal{G}_i^+ = \mathcal{F}_{iK+(M-1)}^+$ for all $i \in \mathbb{N}$. Furthermore, the bounds satisfy

$$M_{q}(\hat{\mathbf{y}}(s)\hat{\mathbf{y}}(s)^{\star}) \leq 8(2q-1)M_{2q}(\mathbf{y})\Gamma_{d,2q}(\mathbf{y})$$

$$\Gamma_{d,q}(\hat{\mathbf{y}}(s)\hat{\mathbf{y}}(s)^{\star}) \leq (48(2q-1)M_{2q}(\mathbf{y})\Gamma_{d,2q}(\mathbf{y})) \cdot$$

$$\left(4\frac{M}{K}\sqrt{2(2q-1)M_{2q}(\mathbf{y})\Gamma_{d,2q}(\mathbf{y})} + \Gamma_{2q}(\mathbf{y})\right).$$

for all $q \geq 1$.

In the rest of this section, we will prove Proposition 3. As we will see, the bounds do not depend on the frequency variable, s, or even the particular window vector, v. They only will require that w(s) is a unit vector (with respect to the Euclidean norm). So, we will drop the dependence on s for compact notation.

The first step in proving Proposition 3 is showing that the vectors $\hat{\mathbf{y}}_i$ are also *L*-mixing.

Lemma 3: If $\mathbf{y}[k]$ is L-mixing with respect to $(\mathcal{F}, \mathcal{F}^+)$, then $\hat{\mathbf{y}}_i$ is L-mixing with respect to $(\mathcal{G}, \mathcal{G}^+)$ where $\mathcal{G}_i = \mathcal{F}_{iK+(M-1)}$ and $\mathcal{G}_i^+ = \mathcal{F}_{iK+(M-1)}^+$ for all $i \in \mathbb{N}$. Furthermore, the bounds satisfy

$$M_{q}(\hat{\mathbf{y}}) \leq 2\sqrt{2((q \vee 2) - 1)M_{q \vee 2}(\mathbf{y})\Gamma_{d,q \vee 2}(\mathbf{y})}$$

$$\Gamma_{d,q}(\hat{\mathbf{y}}) \leq 2\frac{M}{K}M_{q}(\hat{\mathbf{y}}) + \Gamma_{q}(\mathbf{y})$$

for all $q \geq 1$.

Proof: For $q \ge 1$, we use Corollary 2 and the fact that w is a unit vector to give:

$$\begin{aligned} \|\hat{\mathbf{y}}_i\|_{L_{2q}} &= \left\| \sum_{k=0}^{M-1} w_k \mathbf{y}[iK+k] \right\|_{L_{2q}} \\ &\leq 2\sqrt{2(2q-1)M_{2q}(\mathbf{y})\Gamma_{d,2q}(\mathbf{y})} \end{aligned}$$

When $q \ge 2$, the bound on $M_q(\hat{\mathbf{y}})$ follows by replacing 2q with q. For $q \in [1, 2)$, the result follows from monotonicity of the L_q norms.

Now we bound the mixing constant, $\Gamma_{d,q}(\hat{\mathbf{y}})$. By construction, $\hat{\mathbf{y}}_i$ is \mathcal{G}_i measurable for all i and \mathcal{G}_i and \mathcal{G}_i^+ are independent. For all $0 \leq \ell \leq i$, we have (by the triangle inequality, followed by Jensen's inequality):

$$\|\hat{\mathbf{y}}_i - \mathbb{E}[\hat{\mathbf{y}}_i | \mathcal{G}_{i-\ell}^+]\|_{L_q} \le 2M_q(\hat{\mathbf{y}})$$

When $\ell K \ge (M-1)$, we have that $(i-\ell)K+(M-1) = (iK+k)-(\ell K+k-(M-1))$, where $\ell K+k-(M-1) \ge 0$ for all $k = 0, \ldots, M-1$. In this case, using the triangle inequality, and that $|w_k| \le 1$ gives:

$$\begin{split} \|\hat{\mathbf{y}}_{i} - \mathbb{E}[\hat{\mathbf{y}}_{i}|\mathcal{G}_{i-\ell}^{+}]\|_{L_{q}} \\ &\leq \sum_{k=0}^{M-1} \|y[iK+k] - \mathbb{E}[y[iK+k]|\mathcal{F}_{(i-\ell)K+(M-1)}^{+}]\|_{L_{q}} \\ &\leq \sum_{k=0}^{M-1} \gamma_{q}(\ell K + k - (M-1), \mathbf{y}). \end{split}$$

Now, since at most M/K values of ℓ have $\ell < (M-1)/K$, the bound on $\Gamma_q(\hat{\mathbf{y}})$ follows by summing over ℓ .

Now we can use the *L*-mixing properties of $\hat{\mathbf{y}}_i$ to derive the *L*-mixing properties of the outer product, $\hat{\mathbf{y}}_i \hat{\mathbf{y}}_i^*$.

Proof of Proposition 3: Note that for any vectors, $||xy^*||_F = ||x||_2 ||y||_2$. In particular,

$$|\hat{\mathbf{y}}_i \hat{\mathbf{y}}_i^{\star} \|_{L_q} = \|\|\hat{\mathbf{y}}_i\|_2^2 \|_{L_q} = \|\hat{\mathbf{y}}_i\|_{L_{2q}}^2$$

The bound on $M_q(\hat{\mathbf{y}}\hat{\mathbf{y}}^{\star})$ now follows from the bound on $M_{2q}(\hat{\mathbf{y}})$.

To bound the mixing constant, first note that for $0 \le \ell \le i$:

$$\begin{split} \hat{\mathbf{y}}_{i} \hat{\mathbf{y}}_{i}^{\star} &- \mathbb{E} \left[\hat{\mathbf{y}}_{i} \hat{\mathbf{y}}_{i}^{\star} \big| \mathcal{G}_{i-\ell}^{+} \right] \\ &= (\hat{\mathbf{y}}_{i} - \mathbb{E} [\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}]) (\hat{\mathbf{y}}_{i} - \mathbb{E} [\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}])^{\star} \\ &+ (\hat{\mathbf{y}}_{i} - \mathbb{E} [\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}]) \mathbb{E} [\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}]^{\star} \\ &+ \mathbb{E} [\mathbf{y}_{i} | \mathcal{G}_{i-\ell}^{+}] (\hat{\mathbf{y}}_{i} - \mathbb{E} [\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}])^{\star} \\ &+ \mathbb{E} \left[(\hat{\mathbf{y}}_{i} - \mathbb{E} [\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}]) (\hat{\mathbf{y}}_{i} - \mathbb{E} [\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}])^{\star} \right| \mathcal{G}_{i-\ell}^{+}] . \end{split}$$

This equality is derived by plugging in $\hat{\mathbf{y}}_i = (\hat{\mathbf{y}}_i - \mathbb{E}[\hat{\mathbf{y}}_i | \mathcal{G}_{i-\ell}^+]) + \mathbb{E}[\hat{\mathbf{y}}_i | \mathcal{G}_{i-\ell}^+]$ and then simplifying.

Now, using the triangle inequality, followed by Jensen's inequality on the fourth term and conjugate symmetry of the second and third terms gives:

$$\begin{aligned} \left\| \hat{\mathbf{y}}_{i} \hat{\mathbf{y}}_{i}^{\star} - \mathbb{E} \left[\hat{\mathbf{y}}_{i} \hat{\mathbf{y}}_{i}^{\star} \middle| \mathcal{G}_{i-\ell}^{+} \right] \right\|_{L_{q}} \\ &\leq 2 \left\| (\hat{\mathbf{y}}_{i} - \mathbb{E} [\hat{\mathbf{y}}_{i} \middle| \mathcal{G}_{i-\ell}^{+}]) \mathbb{E} [\hat{\mathbf{y}}_{i} \middle| \mathcal{G}_{i-\ell}^{+}]^{\star} \right\|_{L_{q}} \\ &+ 2 \left\| (\hat{\mathbf{y}}_{i} - \mathbb{E} [\hat{\mathbf{y}}_{i} \middle| \mathcal{G}_{i-\ell}^{+}]) (\hat{\mathbf{y}}_{i} - \mathbb{E} [\hat{\mathbf{y}}_{i} \middle| \mathcal{G}_{i-\ell}^{+}])^{\star} \right\|_{L_{q}} \end{aligned}$$
(1)

The first term on the right can be bounded as:

$$\begin{split} \| (\hat{\mathbf{y}}_{i} - \mathbb{E}[\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}]) \mathbb{E}[\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}]^{\star} \|_{L_{q}} \\ &= \left\| \left\| \hat{\mathbf{y}}_{i} - \mathbb{E}[\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}] \right\| \left\| \mathbb{E}[\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}] \right\| \right\|_{L_{q}} \\ \overset{\text{Cauchy-Schwarz}}{\leq} \left\| \hat{\mathbf{y}}_{i} - \mathbb{E}[\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}] \right\|_{L_{2q}} \left\| \mathbb{E}[\hat{\mathbf{y}}_{i} | \mathcal{G}_{i-\ell}^{+}] \right\|_{L_{2q}} \\ &\leq \gamma_{2q}(\ell, \hat{\mathbf{y}}) M_{2q}(\hat{\mathbf{y}}). \end{split}$$

The second term on the right of (1) is bounded similarly:

$$\begin{split} \left\| (\hat{\mathbf{y}}_{i} - \mathbb{E}[\hat{\mathbf{y}}_{i}|\mathcal{G}_{i-\ell}^{+}]) (\hat{\mathbf{y}}_{i} - \mathbb{E}[\hat{\mathbf{y}}_{i}|\mathcal{G}_{i-\ell}^{+}])^{\star} \right\|_{L_{q}} = \\ \left\| \left\| \hat{\mathbf{y}}_{i} - \mathbb{E}[\hat{\mathbf{y}}_{i}|\mathcal{G}_{i-\ell}^{+}] \right\|_{2} \left\| \hat{\mathbf{y}}_{i} - \mathbb{E}[\hat{\mathbf{y}}_{i}|\mathcal{G}_{i-\ell}^{+}] \right\|_{2} \right\|_{L_{q}} \\ \\ \text{Cauchy-Schwarz,} \\ \text{Triangle, Jensen} \end{split}$$

$$\leq 2 \|\hat{\mathbf{y}}_i\|_{L_{2q}} \|\hat{\mathbf{y}}_i - \mathbb{E}[\hat{\mathbf{y}}_i|\mathcal{G}_{i-\ell}^+]\|_{L_{2q}}$$
$$\leq 2M_{2q}(\hat{\mathbf{y}})\gamma_{2q}(\ell, \hat{\mathbf{y}}).$$

Plugging the bounds into (1) and then summing over ℓ gives:

$$\Gamma_{d,q}(\hat{\mathbf{y}}\hat{\mathbf{y}}^{\star}) \leq 6M_{2q}(\hat{\mathbf{y}})\Gamma_{d,2q}(\hat{\mathbf{y}}).$$

The result now follows by plugging in the expressions for $M_{2q}(\hat{\mathbf{y}})$ and $\Gamma_{d,2q}(\hat{\mathbf{y}})$ from Lemma 3.

V. PROOFS OF MAIN RESULTS

After obtaining the necessary L-mixing properties, we are ready to step through proofs of the main results.

A. Proof of Theorem 1

Let $\mathbf{e}_k = \mathbf{x}_k - \bar{z}$ and $\tilde{\mathbf{z}} = \mathbf{z}_k - \bar{z}$. Therefore, we have

$$\mathbf{e}_{k+1} = \mathbf{x}_k - \bar{z} + \alpha_k \left(\left(\mathbf{z}_k - \bar{z} \right) - \left(\mathbf{x}_k - \bar{z} \right) \right) \\ = (1 - \alpha_k) \mathbf{e}_k + \alpha_k \tilde{\mathbf{z}}_k.$$

Iterating gives

$$\mathbf{e}_{k} = \prod_{i=k_{0}}^{k-1} (1-\alpha_{i}) \mathbf{e}_{k_{0}} + \sum_{i=k_{0}}^{k-1} \prod_{j=i+1}^{k-1} (1-\alpha_{j}) \alpha_{i} \tilde{\mathbf{z}}_{i}.$$

Setting $\beta_{i,k} = \prod_{j=i+1}^{k-1} (1 - \alpha_j) \alpha_i \leq \alpha_i$, $\tau_i = \sum_{j=0}^{i-1} \alpha_j$ and for all $q \geq 1$, taking L_{2q} norm on both sides give

7. 1

$$\begin{aligned} \|\mathbf{e}_{k}\|_{L_{2q}} &= \Pi_{i=k_{0}}^{k-1} (1-\alpha_{i}) \|\mathbf{e}_{k_{0}}\|_{L_{2q}} + \|\sum_{i=k_{0}}^{k-1} \beta_{i,k} \tilde{\mathbf{z}}_{i}\|_{L_{2q}} \\ &\leq e^{-(\tau_{k}-\tau_{k_{0}})} \|\mathbf{e}_{k_{0}}\|_{L_{2q}} \\ &+ \sqrt{\sum_{i=k_{0}}^{k-1} \beta_{i,k}^{2}} 2\sqrt{2(2q-1)M_{2q}(\tilde{\mathbf{z}})} \Gamma_{d,2q}(\tilde{\mathbf{z}}) \\ &\leq e^{-(\tau_{k}-\tau_{k_{0}})} \|\mathbf{e}_{k_{0}}\|_{L_{2q}} + \sqrt{\sum_{i=k_{0}}^{k-1} \alpha_{i}^{2}} C_{q}, \end{aligned}$$

$$(2)$$

where $C_q = 2\sqrt{2(2q-1)M_{2q}(\tilde{\mathbf{z}})\Gamma_{d,2q}(\tilde{\mathbf{z}})}$.

Note $\mathbb{E}[\tilde{\mathbf{z}}] = 0$, $M_{2q}(\tilde{\mathbf{z}}) \leq 2M_{2q}(\mathbf{z})$ and $\Gamma_{d,2q}(\tilde{\mathbf{z}}) = \Gamma_{d,2q}(\mathbf{z})$.

For the first inequality above, the first term of the inequality comes from the fact that $1 - x \leq e^{-x}$, $\forall x \in \mathbb{R}$ and the second term of the inequality uses Corollary 2.

Now we choose *m* integer points $0 < s_1 < s_2 \cdots < s_m < k$ to control the iterations of $\|\mathbf{e}_k\|_{L_{2q}}$.

First, setting $k_0 = s_m$ in (2) gives

$$\|\mathbf{e}_{k}\|_{L_{2q}} \leq e^{-(\tau_{k}-\tau_{s_{m}})} \|\mathbf{e}_{s_{m}}\|_{L_{2q}} + \sqrt{\sum_{i=s_{m}}^{k-1} \alpha_{i}^{2} C_{q}}.$$

Then we can bound $\|\mathbf{e}_{s_m}\|_{L_{2q}}$ by setting $k = s_m$ and $k_0 = s_{m-1}$ in (2):

$$\|\mathbf{e}_{s_m}\|_{L_{2q}} \le e^{-(\tau_{s_m} - \tau_{s_{m-1}})} \|\mathbf{e}_{s_{m-1}}\|_{L_{2q}} + \sqrt{\sum_{i=s_{m-1}}^{s_m - 1} \alpha_i^2 C_q}.$$

Iterating this process gives

$$\|\mathbf{e}_{k}\|_{L_{2q}} \leq C_{q} \sum_{l=1}^{m} \sqrt{\sum_{i=s_{l}}^{s_{l+1}-1} \alpha_{i}^{2} e^{-(\tau_{k}-\tau_{s_{l+1}})} + e^{-\tau_{k}} \|\mathbf{e}_{0}\|_{L_{2q}}}.$$

where in the summation, we set $s_{m+1} = k$.

Recall that $\alpha_j = \frac{1}{j+1}$. We can use Riemman approximation to further simplify the bound above.

For $s_l \ge 1, l \in [1, m]$,

$$\sum_{j=s_l}^{s_{l+1}-1} \alpha_j^2 = \sum_{j=s_l}^{s_{l+1}-1} \frac{1}{(j+1)^2} = \sum_{j=s_l+1}^{s_{l+1}} \frac{1}{j^2}$$
$$\leq \int_{s_l}^{s_{l+1}} \frac{1}{t^2} dt = \frac{1}{s_l} - \frac{1}{s_{l+1}} \leq \frac{1}{s_l}.$$

Similarly,

$$\sum_{j=s_l}^{k-1} \alpha_j = \sum_{j=s_l}^{k-1} \frac{1}{j+1} = \sum_{j=s_l+1}^k \frac{1}{j} \ge \int_{s_l+1}^{k+1} \frac{1}{t} dt = \log \frac{k+1}{s_l+1}$$
$$\Rightarrow e^{-\sum_{i=s_l}^{k-1} \alpha_i} = e^{-\tau_k - \tau_{s_l}} \le \frac{s_l+1}{k+1} \le \frac{s_l+1}{k} \le 2\frac{s_l}{k}.$$

Plugging in the bounds gives

$$\|\mathbf{e}_k\|_{L_{2q}} \le 2C_q \sum_{l=1}^m \frac{1}{\sqrt{s_l}} \frac{s_{l+1}}{k} + e^{-\tau_k} \|\mathbf{e}_0\|_{L_{2q}}$$

Let $s_1 = \sqrt{k}$, $\frac{1}{\sqrt{s_1}} \frac{s_2}{k} = \frac{1}{\sqrt{s_2}} \frac{s_3}{k} = \cdots = \frac{1}{\sqrt{s_{m-1}}} \frac{s_m}{k} = k^{-1/2}$. By induction, we can obtain $s_m = k^{\frac{2^m-1}{2^m}}$. Let $\frac{1}{\sqrt{s_m}} \leq \frac{\sqrt{2}}{\sqrt{k}}$, i.e. $s_m \geq \frac{k}{2}$. This inequality gives a lower bound for m:

$$k^{\frac{2^m-1}{2^m}} \ge \frac{k}{2} \Leftrightarrow k^{-\frac{1}{2^m}} \ge \frac{1}{2} \Leftrightarrow m \ge \log_2(\log_2 k)$$

Furthermore, we have the following approximation,

$$e^{-\tau_k} = e^{-\sum_{i=0}^{k-1} \alpha_i} \le \frac{1}{k+1} \le \frac{1}{k} \le \frac{1}{\sqrt{k}} \log_2(\log_2 k)$$

The last inequality holds when $k \ge 4$.

Plugging $\mathbf{x}_0 = 0$ and applying Jensen's inequality gives

$$\begin{aligned} \|\mathbf{e}_{0}\|_{L_{2q}} &= \|\bar{z}\|_{L_{2q}} = \|\mathbb{E}[\mathbf{z}_{k}]\|_{L_{2q}} \\ &\leq \|\mathbf{z}_{k}\|_{L_{2q}} \leq M_{2q}(\mathbf{z}) \leq C_{e,q}. \end{aligned}$$
(3)

Bounding $M_{2q}(\mathbf{z})$ is shown in the proof of Proposition 3. We can choose $m = \log_2(\log_2 k)$ to obtain

$$\|\mathbf{e}_k\|_{L_{2q}} \le (2\sqrt{2}C_q + C_{e,q}) \frac{1}{\sqrt{k}} \log_2(\log_2 k).$$

Note that for Bartlett estimator, M = K and for Welch estimator, we may have $M \neq K$. This results in different constant C_q .

Plugging the bounds from Proposition 3 and the monotonicity of L_q norm ($\|\mathbf{e}_k\|_{L_q} \le \|\mathbf{e}_k\|_{L_{2q}}, \forall q \ge 1$) completes the proof.

B. Proof of Proposition 2 For $0 \le i \le j$ $\|R[j-i]\|_2 = \|\mathbb{E}[\mathbf{y}[j]\mathbf{y}[i]^\top]\|_2$ $= \left\| \mathbb{E} \left[(\mathbf{y}[j] - \mathbb{E}[\mathbf{y}[j] | \mathcal{F}_i^+]) \mathbf{y}[i]^\top \right] \right\|$ $+\mathbb{E}[\mathbb{E}[\mathbf{y}[j]|\mathcal{F}_i^+]\mathbf{y}[i]^\top]\|_2$ $\leq \left\| \mathbb{E}\left[(\mathbf{y}[j] - \mathbb{E}[\mathbf{y}[j] | \mathcal{F}_i^+]) \mathbf{y}[i]^\top \right] \right\|_2$ + $\|\mathbb{E}\left[\mathbb{E}[\mathbf{y}[j]|\mathcal{F}_{i}^{+}]\mathbf{y}[i]^{\top}\right]\|_{2}$ (4)

Now, we focus on bounding the first term of (4),

$$\begin{aligned} & \left\| \mathbb{E} \left[(\mathbf{y}[j] - \mathbb{E}[\mathbf{y}[j] | \mathcal{F}_{i}^{+}]) \mathbf{y}[i]^{\top} \right] \right\|_{2} \\ & \leq \mathbb{E} [\left\| (\mathbf{y}[j] - \mathbb{E}[\mathbf{y}[j] | \mathcal{F}_{i}^{+}]) \mathbf{y}[i]^{\top} \right\|_{2}] \\ & \leq \mathbb{E} [\left\| \mathbf{y}[j] - \mathbb{E}[\mathbf{y}[j] | \mathcal{F}_{i}^{+}] \right\| \left\| \mathbf{y}[i] \right\|] \\ & \leq \sqrt{\mathbb{E} [\left\| \mathbf{y}[j] - \mathbb{E}[\mathbf{y}[j] | \mathcal{F}_{i}^{+}] \right\|^{2}} \sqrt{\mathbb{E} [\left\| \mathbf{y}[i] \right\|^{2}]} \\ & \leq M_{2}(\mathbf{y}) \gamma_{2}(j - i, \mathbf{y}) \end{aligned}$$

where the first inequality uses Jensen's inequality and the second inequality uses some inequalities of norms: For vector $x, y, \|xy^*\|_2 \le \|xy^*\|_F = \|x\|_2\|y\|_2$. The third inequality uses Cauchy Schwarz inequality.

For the second term of (4), we uses the independence of $\mathbb{E}[\mathbf{y}[j]|\mathcal{F}_i^+]$ and $\mathbf{y}[i]$, which is because $\mathbf{y}[i]$ is \mathcal{F}_i -measurable and \mathcal{F}_i^+ and \mathcal{F}_i are independent. Therefore, the following holds:

$$\mathbb{E}\left[\mathbb{E}[\mathbf{y}[j]|\mathcal{F}_i^+]\mathbf{y}[i]^\top\right] = \mathbb{E}\left[\mathbb{E}[\mathbf{y}[j]|\mathcal{F}_i^+]\right]\mathbb{E}[\mathbf{y}[i]^\top] = 0$$

where the last inequality is from the zero-mean assumption.

The bounds when $0 \ge i \ge j$ are derived similarly.

It follows that

$$||R[k]||_2 \le 2M_2(\mathbf{y})\gamma_2(|k|, \mathbf{y})$$

for all integers, k.

The rest now follows from bias calculations from [11]. ■

C. Proof of Theorem 2

For all $\epsilon > 0$ and all $q \ge 1$, Markov's inequality, followed by Theorem 1 implies:

$$\mathbb{P}(\|\mathbf{x}_{k} - \bar{z}\| > \epsilon) = \mathbb{P}(\|\mathbf{x}_{k} - \bar{z}\|^{q} > \epsilon^{q})$$

$$\leq \epsilon^{-q} \|\mathbf{x}_{k} - \bar{z}\|_{L_{q}}^{q}$$

$$\leq \epsilon^{-q} f_{k}^{q} q^{rq}, \qquad (5)$$

where

$$f_k = c \frac{\log_2(\log_2(k))}{\sqrt{k}}.$$

The logarithm of the upper bound in (5) is:

$$g(q) = q \ln(\epsilon^{-1} f_k) + rq \ln q,$$

which is convex in q. The global minimum is given by:

$$\operatorname*{arg min}_{q>0} g(q) =: q^{\star} = e^{-1} \left(\frac{\epsilon}{f_k}\right)^{\frac{1}{r}}$$

with $q^{\star} \geq 1$ when $\epsilon \geq f_k e^r$.

Thus, as long as $\epsilon \geq f_k e^r$, we have

$$\mathbb{P}(\|\mathbf{x}_k - \bar{z}\| > \epsilon) \le (\epsilon^{-1} f_k (q^*)^r)^{q^*} = e^{-\frac{r}{\epsilon} \left(\frac{\epsilon}{f_k}\right)^{\frac{1}{r}}}.$$

Fix $\nu \in (0,1)$. Then $e^{-\frac{r}{e}\left(\frac{\epsilon}{f_k}\right)^{\frac{1}{r}}} \leq \nu$ if and only if

$$\epsilon \geq f_k e^r \frac{(\ln \nu^{-1})'}{r^r}.$$

Thus, if $\epsilon = f_k e^r \max\left\{1, \frac{(\ln \nu^{-1})^r}{r^r}\right\}$, then $\mathbb{P}(\|\mathbf{x}_k - \bar{z}\| > \epsilon) \leq \nu.$

D. Proof of Proposition 1

Let $\zeta_i[k] = \mathbf{v}$ be a σ -sub-Gaussian random variable. We first derive moment bounds on $\zeta[k]$, and use them to derive moment bounds on $\mathbf{y}[k]$. We follow the basic steps of Proposition 2.5.2 in [23], but track the constants more specifically.

$$\begin{split} \mathbb{E}[|\mathbf{v}|^{q}] &= \int_{0}^{\infty} \mathbb{P}(|\mathbf{v}|^{q} > \epsilon) d\epsilon \\ &= \int_{0}^{\infty} \mathbb{P}(|\mathbf{v}| > \epsilon^{1/q}) d\epsilon \\ &= \int_{0}^{\infty} (\mathbb{P}(\mathbf{v} > \epsilon^{1/q}) + \mathbb{P}(-\mathbf{v} > \epsilon^{1/q})) d\epsilon. \end{split}$$

For all $\lambda > 0$, we have:

$$\mathbb{P}(\mathbf{v} > \epsilon^{1/q}) = \mathbb{P}(e^{\lambda \mathbf{v}} > e^{\lambda \epsilon^{1/q}})$$

$$\leq e^{-\lambda \epsilon^{1/q}} \mathbb{E}[e^{\lambda \mathbf{v}}]$$

$$\leq \exp\left(-\lambda \epsilon^{1/q} + \frac{1}{2}\lambda^2 \sigma^2\right).$$

Minimizing the bound over λ shows that

$$\mathbb{P}(\mathbf{v} > \epsilon^{1/q}) \le \exp\left(-\frac{\epsilon^{2/q}}{2\sigma^2}\right)$$

The same upper bound holds for $\mathbb{P}(-\mathbf{v} > \epsilon^{1/q})$, so that

$$\mathbb{E}[|\mathbf{v}|^{q}] \leq 2 \int_{0}^{\infty} \exp\left(-\frac{\epsilon^{2/q}}{2\sigma^{2}}\right) d\epsilon$$
$$\stackrel{t=\frac{\epsilon^{2/q}}{\underline{=}\sigma^{2}}}{=} q 2^{q/2} \sigma^{q} \int_{0}^{\infty} e^{-t} t^{\frac{q}{2}-1} dt$$
$$= q (\sqrt{2}\sigma)^{q} \Gamma(q/2)$$
$$\leq 3q (\sqrt{2}\sigma)^{q} (q/2)^{q/2}$$
$$= e q \sigma^{q} q^{q/2}$$

where the second inequality uses the Stirling bound $\Gamma(x) \le ex^x$ for $x \ge 1/2$.

It follows that

$$\begin{aligned} \|\mathbf{v}\|_{L_q} &\leq e^{\frac{1}{q}} q^{\frac{1}{q}} \sigma \sqrt{q} \\ &\leq e^2 \sigma \sqrt{q} \leq 8 \sigma \sqrt{q}. \end{aligned}$$

where the second inequality uses that $q^{\frac{1}{q}} \leq e$ for $q \geq 1$.

Now, using the triangle inequality, it follows that $M_q(\zeta) \leq 8m\sigma\sqrt{q}$.

Using the bound on $M_q(\boldsymbol{\zeta})$, we can bound $M_q(\mathbf{y})$. Indeed, $\|h[k-\ell]\boldsymbol{\zeta}[\ell]\|_2 \leq \|h[k-\ell]\|_2 \|\boldsymbol{\zeta}[\ell]\|_2$ implies that

$$\|\mathbf{y}[k]\|_{L_q} \le M_q(\boldsymbol{\zeta}) \sum_{\ell=0}^{\infty} \|h[\ell]\|_2.$$

The bound on $M_q(\mathbf{y})$ now follows.

To bound $\Gamma_{d,q}(\mathbf{y})$, let $\mathcal{F}_k = \sigma\{\boldsymbol{\zeta}[\ell] | \ell \leq k\}$ and $\mathcal{F}_k^+ = \sigma\{\boldsymbol{\zeta}[\ell] | \ell > k\}$. Then for $0 \leq \ell \leq k$

$$\begin{split} \left\| \mathbf{y}[k] - \mathbb{E}[\mathbf{y}[k] | \mathcal{F}_{k-\ell}^+] \right\|_{L_q} &= \left\| \sum_{p=-\infty}^{k-\ell} h[k-p] \boldsymbol{\zeta}[p] \right\|_{L_q} \\ &\leq M_q(\boldsymbol{\zeta}) \sum_{p=\ell}^{\infty} \|h[p]\|_2. \end{split}$$

It follows that

$$\begin{split} \Gamma_{d,q}(\mathbf{y}) &\leq M_q(\boldsymbol{\zeta}) \sum_{\ell=0}^{\infty} \sum_{p=\ell}^{\infty} \|h[p]\|_2 \\ &= M_q(\boldsymbol{\zeta}) \sum_{\ell=0}^{\infty} \|h[\ell]\|_2 (\ell+1). \end{split}$$

VI. SIMULATION

To verify the obtained error bounds for the two classical spectrum estimators, samples are generated from measurements of a finite-state Markov chain. The stochastic process $\mathbf{y}[k] \in \{0,1\} \subset \mathbb{R}$ corresponds to the sequence of states generated via the Markov chain with transition matrix $P = \begin{bmatrix} 0.3 & 0.7 \\ 0.5 & 0.5 \end{bmatrix}$ The unique stationary distribution of the Markov chain is $\mu = [5/12, 7/12]$, which gives $\mathbb{E}[\mathbf{y}[k]] = 7/12$. Note to match the zero-mean assumption of this work, we can simply shift measurements by the mean $\mathbb{E}[\mathbf{y}[k]]$ in the simulation.

It can be proved that such an ergodic finite-state markov chain $\mathbf{y}[k]$ is L-mixing [17]. Proposition 4.1 of [17] also calculates an upper bound of the *L*-mixing statistics $\Gamma_{d,q}(\mathbf{y})$. Note that the Doeblin coefficient in our example is $\delta = \min\{0.3/(5/12), 0.5/(7/12)\} = 0.72$. Let $G_{\max} = \max_k \|\mathbf{y}[k]\|$. Therefore, $\Gamma_{d,4q}(\mathbf{y}) \leq 4G_{\max}\frac{1}{1-(1-\delta)^{\frac{1}{4q}}} \leq \frac{4G_{\max}}{\delta}4q$. Furthermore, $M_{4q}(\mathbf{y}) \leq G_{\max}$. This allows the explicit computation of the bound shown in Theorem 2.

We use both Bartlett and Welch estimators to esimate power spectral density $\Phi(s)$ of the stochastic process at $s = \frac{1}{2}$. The convergence results are shown in Fig. 1, which present the errors of the algorithms $(||\mathbf{x}_k - \bar{z}||)$ and the theoretical bound in Theorem 2. We set $\nu = 0.1$, meaning the theoretical bound holds with probability 0.9. We can see the empirical errors are all well below the theoretical bound. We are aware that these bounds are quite conservative. Getting a tighter bound is likely by improving some of the bounding techniques but not in the scope of this study.

VII. CONCLUSION AND FUTURE WORK

In this work, we obtained the finite-time convergence rate for two classical spectrum estimators. The error bounds corresponding to the variance of the estimators can be quantified by the *L*-mixing properties of the data. For Bartlett estimator, the concentration bound is independent of the window length M, while for Welch estimator, it depends on the ratio between M and K, which is usually fixed as 0.5 in practice. We showed the convergence rate of the algorithm is of order $O(\frac{1}{\sqrt{k}} \log_2(\log_2 k))$, where k is the number of chunks of data used in the algorithm.

One limitation is that the zero-mean assumption on the time series often will not hold. Therefore, in the future, we will extend the current analysis to more general time series which are not necessarily zero-mean. Another future direction is to improve the constant factors.
