Abstract. The classical theory for the meta-analysis of p -values is based on the assumption that if the overall null hypothesis is true, then all p -values used in a chosen combined test statistic are genuine, i.e., are observations from independent and identically distributed standard uniform random variables. However, the pressure felt by most researchers to publish, which is worsened by publication bias, can originate fake p -values to be reported, usually Beta(1,2) distributed. In general, the existence of fake p -values in a sample of p -values to be combined is unknown, and if, for some reason, there is information that they do exist, their number will most likely be unknown as well. Moreover, even if fake p -values are accounted for, the cumulative distribution function of classical combined test statistics does not have a closed-form expression that facilitates its practical usage. To overcome this problem, tables with estimated critical values are supplied for the commonly used combined tests for the meta-analysis of p -values when a few of them are fake ones, i.e., Beta(1,2) distributed.

1. Introduction

The concept of p -value, defined as the probability of obtaining a result equal to or more extreme than what was actually observed, under a null hypothesis H_0 of no effect or of no difference, plays a key role in Fisher's theory of significance testing. Under the assumption that H_0 is true, the p -value is an observation from a random variable $P \sim \text{Uniform}(0, 1)$, which is a simple consequence of the probability integral transform theorem. On the other hand, a p -value smaller than 0.05, considered by Fisher (Fisher, 1922, 1925) to be a threshold for a significant value, only hints that the experiment should be repeated; quoting Fisher (1926), p. 85,

"A scientific fact should be regarded as experimentally established only if a properly designed experiment rarely fails to give this [$p = 0.05$] level of significance",

2010 *Mathematics Subject Classification.* 62A01, 62P10, 62Q05.

Key words and phrases. Combined tests, meta-analysis of p -values, genuine and fake p -values, tables with critical values.

The authors are members of Centro de Estatística e Aplicações, Universidade de Lisboa (CEAUL). This research has been partially supported by National Funds through FCT — Fundação para a Ciência e Tecnologia, project UIDB/00006/2020 (<https://doi.org/10.54499/UIDB/00006/2020>).

thus raising the issue of independently replicating experiments and of combining tests, i.e., testing the overall null hypothesis H_0^* : all the $H_{0,k}$, $k = 1, \dots, n$, are true *vs.* the alternative hypothesis H_A^* : not all $H_{A,k}$, $k = 1, \dots, n$, are false.

The classical combined test statistics for the meta-analysis of p -values are briefly described in Section 2. Section 3 discusses the possibility of some of the p -values to be combined being fake p -values, due to malpractice or to fraudulent non-reported replication of an experiment. As in such framework there is no closed-form expressions for the cumulative distribution functions of the combined test statistics, in Section 4, the simulation methodology used to obtain estimated high and low quantiles is described. The tables with the quantiles are supplied in the Appendix.

2. Combined Test Statistics for the Meta-Analysis of Genuine p -Values

Under the validity of the overall null hypothesis H_0^* , there are several combined methods to choose from to carry out meta-analysis of genuine p -values. The most commonly used combined methods are listed below and for each one, its test statistic $T(P_1, \dots, P_n)$ is indicated.

- (1) Tippett's method (Tippett, 1931):

$$T_T(P_1, \dots, P_n) = \min\{P_1, \dots, P_n\} = P_{1:n}.$$

- (2) Fisher's method (Fisher, 1932):

$$T_F(P_1, \dots, P_n) = -2 \sum_{k=1}^n \ln P_k.$$

- (3) Pearson's geometric mean method (Pearson, 1933):

$$T_{G_n}(P_1, \dots, P_n) = \left(\prod_{k=1}^n P_k \right)^{1/n}.$$

- (4) Pearson's minimum of geometric means method (Pearson, 1934):

$$T_{G_n, G_n^*}(P_1, \dots, P_n) = \min \left\{ \left(\prod_{k=1}^n P_k \right)^{1/n}, \left(\prod_{k=1}^n (1 - P_k) \right)^{1/n} \right\},$$

which is useful in a bilateral context.

- (5) Stouffer et al.'s method (Stouffer et al., 1949):

$$T_S(P_1, \dots, P_n) = \sum_{k=1}^n \frac{\Phi^{-1}(P_k)}{\sqrt{n}},$$

with Φ^{-1} denoting the inverse of the standard Gaussian cumulative distribution function.

- (6) Wilkinson's method (Wilkinson, 1951):

$$T_W(P_1, \dots, P_n) = P_{k:n}, \quad \text{for a } k = 1, \dots, n,$$

thus generalizing Tippett's method.

- (7) Edgington's arithmetic method (Edgington, 1972):

$$T_E(P_1, \dots, P_n) = \bar{P}_n = \frac{\sum_{k=1}^n P_k}{n}.$$

- (8) Mudholkar and George's method (Mudholkar and George, 1979):

$$T_{MG}(P_1, \dots, P_n) = - \sum_{k=1}^n \ln \left(\frac{P_k}{1 - P_k} \right).$$

(9) Wilson's harmonic mean method (Wilson, 2019):

$$T_{\mathcal{H}_n}(P_1, \dots, P_n) = \frac{n}{\sum_{k=1}^n 1/P_k}.$$

(10) Chen's method (Chen, 2022):

$$T_C(P_1, \dots, P_n) = \sum_{k=1}^n [\Phi^{-1}(P_k)]^2.$$

Littell and Folks (1971, 1973) showed that, under mild conditions, Fisher's method is optimal for combining independent tests, while Mosteller and Bush (1954) and Whitlock (2005) recommend Stouffer et al.'s method. On the other hand, Birnbaum (1954) showed that every monotone combined test procedure is admissible, i.e., provides a most powerful test against some alternative hypothesis for combining some collection of tests, and therefore is optimal for some combined testing situation whose goal is to harmonize possibly conflicting evidence, or to pool inconclusive evidence. Therefore, to reach an overall decision, it is advisable to take into consideration the above list of combined tests.

3. Fake p -Values

It is however naive to assume that all observed p_k 's to be combined are genuine p -values. Quoting Fisher on his critical judgement of Mendel's work (Fisher, 1936, p. 132),

"[...] the data of most, if not all, of the experiments have been falsified so as to agree closely with Mendel's expectations."

As a result, the Mendel-Fisher controversy started a debate on scientific research malpractices and scientific fraudes (ab)using Statistics (see Franklin et al., 2008, and Pires and Branco, 2010).

As publication bias implies that non-significant results are less likely to be published (Givens et al., 1997; Pestana et al., 2013; Jin et al., 2015; Lin and Chu, 2018), this fact can lead to inappropriate replication of experiments when the observed p -value of the initial experiment is greater than 0.05, in the hope of obtaining a "better" p -value, i.e., a smaller p -value. In many cases, what will happen is that both p -values obtained are greater than 0.05, thus not being worthy of being reported, and consequently the replication of the experiment is discouraged.

In view of the possibility of an experimenter reporting the smallest of two p -values when a second p -value is obtained, the p -value that is actually reported is a fake p -value that is Beta(1,2) distributed, since it is the minimum of two independent standard uniform random variables.

This clearly changes the distribution of the combined test statistics. For instance, in Fisher's method, if P_1^*, \dots, P_ℓ^* are fake p -values such that $P_k^* \sim \text{Beta}(1, 2)$ for $k = 1, \dots, \ell$, and $P_{\ell+1}, \dots, P_n$ are genuine p -values, i.e., $P_j \sim \text{Uniform}(0, 1)$ for $j = \ell+1, \dots, n$, then $-4 \sum_{k=1}^{\ell} \ln(1 - P_k^*) \sim \chi_{2\ell}^2$ and $-2 \sum_{j=\ell+1}^n \ln P_j \sim \chi_{2(n-\ell)}^2$, and therefore $-4 \sum_{k=1}^{\ell} \ln(1 - P_k^*) - 2 \sum_{j=\ell+1}^n \ln P_j \sim \chi_{2n}^2$. Moreover, there are so far no reliable procedures to estimate which p -values are the fake ones, let alone how many exist.

With the exception of Tippett's statistic $T_T(P_1, \dots, P_n) = P_{1:n}$, the other combined test statistics have a distribution that does not allow a closed-form expression for its cumulative distribution function when there are $n_f \geq 1$ fake p -values in the sample. For further details, see Brillhante et al. (2024).

4. Simulation Notes

As already mentioned, it is in general impossible to know whether there are or not fake p -values among the set of p -values to be combined. Therefore, a realistic approach is to examine possible

scenarios and assess how the existence of fake p -values can affect the decision on the overall null hypothesis H_0^* .

The combination of genuine and false p -values for any of the above methods requires the existence of critical values. In the collection of indicated methods, Tippett's statistic $T_T(P_1, \dots, P_n) = P_{1:n}$ is a rather exceptional case, since when there are $n_f \geq 1$ fake p -values in the sample, we have $P_{1:n}|H_0^* \sim \text{Beta}(1, n + n_f)$. However, for the other combined test statistics, there are no closed-form expressions for the cumulative distribution functions when there are $n_f \geq 1$ fake p -values in the sample. This situation makes it hard to obtain exact critical values that are necessary for hypothesis testing. To overcome this problem, a simple simulation was carried out with the software R (version 4.3.1), a language and environment for statistical computing (R Core Team, 2023), to obtain the q -th quantile estimate, for $q = 0.005, 0.01, 0.025, 0.05, 0.1, 0.9, 0.95, 0.975, 0.99, 0.995$, of the combined test statistics' distributions when some of the p -values are fake ones.

Since each genuine p -value follows a standard uniform distribution and a fake p -value a Beta(1, 2) distribution, to estimate the quantiles of the test statistics, the following methodology was used.

A total of $N = 4999$ samples of p -values of size $n = 3, \dots, 26$ were generated, for which there are at most $\lfloor n/3 \rfloor$ fake p -values in each sample (i.e., $n_f \leq \lfloor n/3 \rfloor$). For each generated sample, the combined test statistic $T(P_1, \dots, P_n)$ was computed, thus originating an observed sample of the test statistic $(t_{1:n,n_f}, \dots, t_{N:N;n,n_f})$. The sample of order statistics $(t_{1:N;n,n_f}, \dots, t_{N:N;n,n_f})$ was then used to estimate the q -th quantile as $\hat{t}_{n,n_f;q} = t_{\lfloor q(N+1) \rfloor:N;n,n_f}$ (see Davison and Hinkley, 1997, pp. 18-19). This procedure was repeated $R = 50$ times so that a sample of size R of estimates of each q -th quantile was recorded, i.e., $(\hat{t}_{n,n_f;q}^{(1)}, \dots, \hat{t}_{n,n_f;q}^{(R)})$. The final estimate of the q -th quantile of $T(P_1, \dots, P_n)$ is the average of the values $\hat{t}_{n,n_f;q}^{(i)}$, $i = 1, \dots, R$, i.e.,

$$\tilde{T}_{n,n_f;q} = \frac{1}{R} \sum_{i=1}^R \hat{t}_{n,n_f;q}^{(i)}, \text{ with standard error } s_{\tilde{T}_{n,n_f;q}} = \sqrt{\frac{\sum_{i=1}^R (\hat{t}_{n,n_f;q}^{(i)} - \tilde{T}_{n,n_f;q})^2}{R(R-1)}}.$$

By applying the central limit theorem, an approximate $(1 - \alpha)100\%$ confidence interval for the q -th quantile of $T(P_1, \dots, P_n)$ can be easily computed using the interval

$$\left(\tilde{T}_{n,n_f;q} - z_{1-\alpha/2} \times s_{\tilde{T}_{n,n_f;q}}, \tilde{T}_{n,n_f;q} + z_{1-\alpha/2} \times s_{\tilde{T}_{n,n_f;q}} \right),$$

where z_q denotes the q -th quantile of the standard Gaussian distribution.

The tables with the estimated quantiles, in a few cases exact, are supplied in the Appendix for sample sizes $n = 3, \dots, 26$, and when there are at most $n_f \leq \lfloor n/3 \rfloor$ fake p -values. Notice that when only genuine p -values are in the sample, i.e., $n_f = 0$, the critical values of T_F , T_S , T_C , T_W and T_{G_n} indicated in the tables are exact (the exact critical values of T_{G_n} were obtained with Mathematica v12). This also holds true for the case of the critical values of Tippett's combined test statistic $T_T(P_1, \dots, P_n) = P_{1:n+n_f} \sim \text{Beta}(1, n + n_f)$, regardless of the value of n_f . We have, nonetheless, simulated the critical values for Tippett's statistic, just for comparison purposes as shown below.

The estimates obtained with the methodology described above can be compared with the exact values to establish the reliability of the simulation results. Figure 4.1 illustrates the convergence of the estimated cumulative distribution function as a function of the number of samples. It shows that there is almost no difference between the use of $N = 2500$ or $N = 4999$ samples for Tippett's statistic $T_T(P_1, \dots, P_n) = P_{1:n}$, with $n = 5$ and $n_f = 3$, and also for Chen's statistic $T_C(P_1, \dots, P_n) = \sum_{k=1}^n [\Phi^{-1}(P_n)]^2$, with $n = 10$ and $n_f = 0$.

Figure 4.2 depicts the estimated cumulative distribution function for each of the $R = 50$ replicas. It reveals great stability for $N = 4999$ samples since the 50 curves seem to overlap perfectly. This shows that the methodology used has produced accurate and precise estimates of the quantiles.

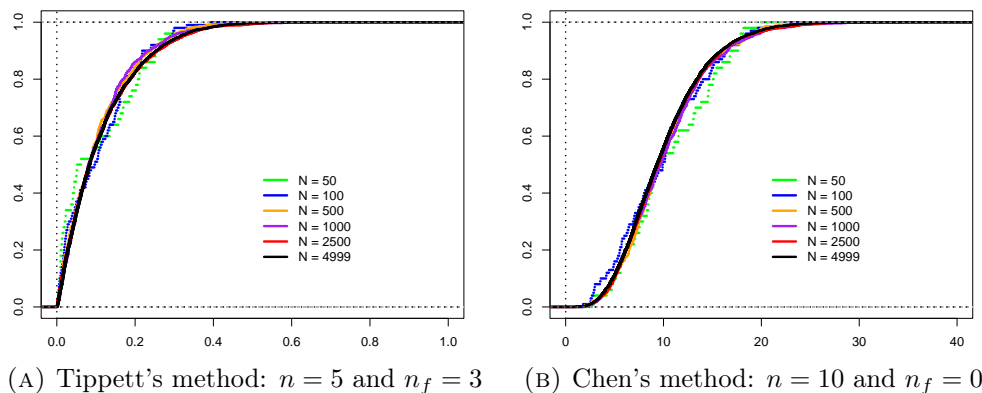

FIGURE 4.1. Estimated cumulative distribution functions using samples of size $N = 50, 100, 500, 1000, 2500, 4999$

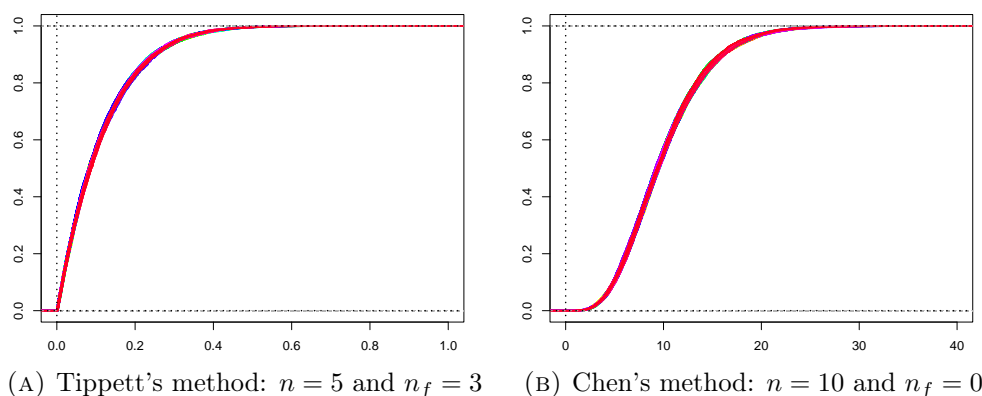

FIGURE 4.2. Fifty estimated cumulative distribution function with $N = 4999$ samples each

Since Tippet's statistic has a known distribution, namely a $\text{Beta}(1, n + n_f)$ distribution, and the same goes for Chen's statistic, which is chi-square distributed with n degrees of freedom if $n_f = 0$, the estimated cumulative distribution functions of both cases can be compared to the theoretical ones. Therefore, Figure 4.3 displays the theoretical and the estimated cumulative distribution functions using $N = 4999$ samples, for Tippet's minimum method using $n = 5$ and $n_f = 3$ ($\text{Beta}(1, 8)$ distribution), and for Chen's method using $n = 10$ and $n_f = 0$ (χ^2_{10} distribution).

5. Conclusion

Combining genuine and fake p -values with any of the combined methods seen in Section 2, requires the tabulation of critical values, because the cumulative distribution functions of these statistics are generally not known in a closed-form expression. This work provides estimated quantiles, and their standard errors, for the classical combined test statistics for sample sizes $n = 3, \dots, 26$ when there are at most $n_f \leq \lfloor n/3 \rfloor$ fake p -values.

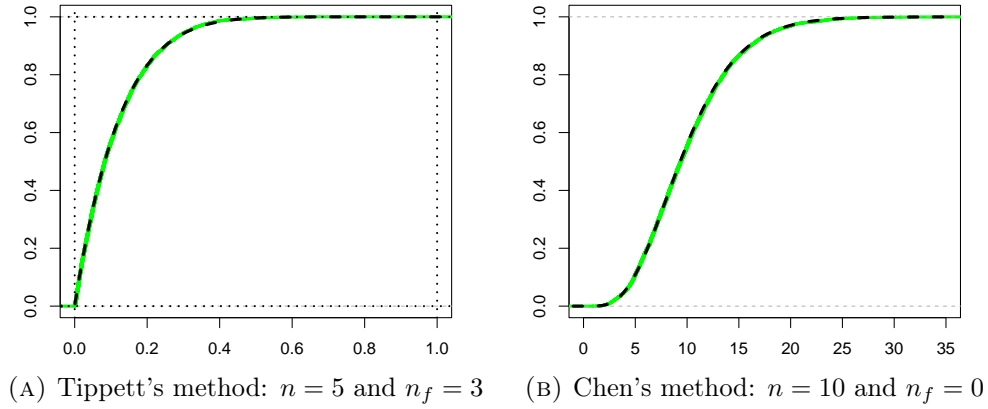

FIGURE 4.3. Theoretical (black dashed line) and estimated (green solid line) cumulative distribution functions

Appendix A.

The tables with the critical values for the listed methods are organized as follows:

Method	Statistic	Table
Fisher	$-2 \sum_{k=1}^n \ln P_k$	A.1
Stouffer et al.	$\frac{\sum_{k=1}^n \Phi^{-1}(P_k)}{\sqrt{n}}$	A.2
Chen	$\sum_{k=1}^n [\Phi^{-1}(P_k)]^2$	A.3
Mudholkar and George	$-\sum_{k=1}^n \ln\left(\frac{P_k}{1-P_k}\right)$	A.4
Geometric mean	$(\prod_{k=1}^n P_k)^{1/n}$	A.5
Minimum of geometric means	$\min \left\{ (\prod_{k=1}^n P_k)^{1/n}, (\prod_{k=1}^n (1 - P_k))^{1/n} \right\}$	A.6
Wilson	$\frac{n}{\sum_{k=1}^n 1/P_k}$	A.7
Edgington	$\frac{1}{n} \sum_{k=1}^n P_k$	A.8
Tippett	$P_{1:n}$	A.9
Wilkinson	$P_{n:n}$	A.10

Fisher's statistic $T_F(P_1, \dots, P_n) = -2 \sum_{k=1}^n \ln P_k$ TABLE A.1. Quantiles of T_F with n_f fake p -values [estimate (standard error)]
