*Abstract*—This paper aims to prove the significant superiority of hybrid non-orthogonal multiple access (NOMA) over orthogonal multiple access (OMA) in terms of energy efficiency. In particular, a novel hybrid NOMA scheme is proposed in which a user can transmit signals not only by using its own time slot but also by using the time slots of other users. The data rate maximization problem is studied by optimizing the powe r allocation, where closed-form solutions are obtained. Furthermore, the conditions under which hybrid NOMA can achieve a higher instantaneous data rate with less power consumption than OMA are obtained. It is proved that the probability that hybrid NOMA can achieve a higher instantaneous data rate with less power consumption than OMA approaches one in the high SNR regime, indicating the superiority of hybrid NOMA in terms o f power efficiency. Numerical results are also provided to verify the developed analysis and also to demonstrate the superior performance of hybrid NOMA.

*Index Terms*—Hybrid NOMA, energy efficiency, power allocation, data rate maximization, performance analysis

#### I. INTRODUCTION

The development of next-generation multiple access (NGMA) techniques to enable sixth-generation (6G) mobile communications has recently attracted considerable attention and effort from both academia and industry [\[1\]](#page-4-0). In particular, non-orthogonal multiple access (NOMA) has been recognized as an important candidate for NGMA [\[2\]](#page-4-1)–[\[4\]](#page-4-2). For example, NOMA is expected to be considered to meet the future requirements of the recently released International Mobil e Telecommunications (IMT)-2030 Framework [\[5\]](#page-4-3).

Hybrid NOMA, which can be treated as a general form of NOMA and conventional orthogonal multiple access (OMA), has been proposed recently [\[6\]](#page-4-4)–[\[8\]](#page-4-5). Unlike existing scheme s in [\[9\]](#page-4-6), [\[10\]](#page-4-7), where a user can choose to transmit in either OMA or NOMA, in hybrid NOMA, a user can divide its transmission into several orthogonal subchannels (which can be time slots [\[6\]](#page-4-4), subcarriers [\[8\]](#page-4-5), spatial beams [\[7\]](#page-4-8), etc.), and in each subchannel, the user can transmit either in NOMA mode or OMA mode. The advantages of NOMA are mainly twofold [\[8\]](#page-4-5). One is its flexibility in implementation, since hybrid NOMA can be developed as a simple add-on to the existing OMA-based legacy network framework. The other is its effective resource utilization, since hybrid NOMA allows multidimensional resource allocation, which provides mor e freedom for optimization.

Although promising, research on hybrid NOMA is still in its infancy. This paper aims to investigate the superior advantage of hybrid NOMA in terms of energy efficiency by seeking the answer to the following fundamental question: can hybrid NOMA achieve a higher data rate while consuming less energy than OMA? The main contributions of this thesis are as follows:

- A novel hybrid NOMA scheme is proposed, where a user can transmit signals not only by using its own timeslot, but also by using other users' timeslots. The instantaneous data rate maximization problem for the proposed hybrid NOMA scheme is solved with a closed-form solution.
- Based on the obtained expression for the achievable data rate of hybrid NOMA, the comparisons with OMA are made. Specifically, the conditions under which hybrid NOMA can achieve a higher instantaneous data rate with less energy consumption compared to pure OMA are provided. Furthermore, the probability of these condition s is analyzed taking into account the randomness of the channel gains. It is shown that the probability for hybrid NOMA to achieve a higher instantaneous data rate with less power consumption compared to OMA approaches one in the high SNR regime.

#### II. SYSTEM MODEL

Consider a legacy TDMA based uplink communication scenario with one base station, and two users which are denoted by  $U_m$  and  $U_n$ , respectively, as shown in Fig. [1.](#page-1-0) Each user is allocated with an individual time slot with duration  $T$ . Thus the achievable instantaneous data rate of  $U_v$   $(v \in \{m, n\})$  in TDMA is given by

$$
R_v^{\text{OMA}} = \log\left(1 + |h_v|^2 \rho_v\right),\tag{1}
$$

where  $h_v$  is the small-scale fading modeled as a circularly symmetric complex gaussian (CSCG) random variable with mean zero and variance 1, i.e.,  $h_v \sim \mathcal{CN}(0, 1)$ , and  $\rho_v$  is the transmit power. It is worth noting that the additive background noise power is normalized in this paper.

It is assumed that  $U_m$  is a quality of service (QoS) sensitive user which has a target data rate denoted by  $R_0$ . Specifically, when the achievable data rate  $R_m^{\text{OMA}}$  is larger than  $R_0$ ,  $U_m$ only wants to transmit with  $R_0$  instead of a higher data rate; and when  $R_m^{\text{OMA}} \leq R_0$ ,  $U_m$  would like to transmit with  $R_m^{\text{OMA}}$  which is most close to  $R_0$  for reliable transmission. On the other hand,  $U_n$  wants to transmit as much data as possible. Based on the above assumptions, the considered hybrid NOMA scheme allows  $U_n$  to have an additional transmitting opportunity by transparently sharing  $U_m$ 's slot (NOMA transmission), in addition to its own dedicated slot (OMA transmission). Note that the "transparency" means tha t the admission of  $U_n$  to  $U_m$ 's slot should not degrade the

<span id="page-1-0"></span>

Fig. 1: Illustration of the system model.

performance of  $U_m$  compared to OMA. The achievable rates of  $U_n$  in the considered hybrid NOMA scheme for NOMA and OMA transmission are given by:

• for NOMA transmission,  $U_n$  transmits signals with power  $\beta_1 \rho_n$ , where  $\beta_1$  is the power coefficient,  $0 \leq \beta_1 \leq 1$ . The BS first decodes  $U_m$ 's signal, and if succeeded, successive interference cancellation (SIC) will be carried out and  $U_n$ 's signal can be decoded without any interference, yielding the following data rate:

$$
R_n^1 = \log (1 + \beta_1 \rho_n |h_n|^2). \tag{2}
$$

To ensure the success of SIC, the transmit power of  $U_n$  needs to satisfy  $\beta_1 \rho_n |h_n|^2 \leq \tau_m$ , where  $\tau_m$  =  $\max\{0, \rho_m |h_m|^2/\epsilon_0 - 1\}, \epsilon_0 = 2^{R_0} - 1.$  Note that  $\tau_m$  can be treated as the maximal interfering power with which  $U_m$ 's signal can be successfully decoded [\[11\]](#page-4-9).

• for OMA transmission,  $U_n$  transmits signals with power  $\beta_2 \rho_n$ , where  $\beta_2$  is the power coefficient,  $0 \leq \beta_2 \leq 1$ , yielding the following data rate:

$$
R_n^2 = \log(1 + \beta_2 \rho_n |h_n|^2). \tag{3}
$$

Thus, the achievable rates of  $U_n$  in the considered hybrid NOMA scheme can be expressed as  $R_n = R_n^1 + R_n^2$ .

# III. RATE MAXIMIZATION FOR HYBRID NOMA AND COMPARISONS WITH PURE OMA

Since the proposed hybrid NOMA scheme ensures that  $U_m$  has the same performance as in OMA, the rest of the paper will focus on the performance of  $U_n$  to unveil the advantages of hybrid NOMA. To this end, the following data rate maximization problem is first formulated:

$$
\max_{\beta_1, \beta_2} \qquad R_n \tag{4a}
$$

s.t.  $\beta_1 + \beta_2 \leq \eta$ , (4b)

$$
\beta_1 \rho_n |h_n|^2 \le \tau_m,\tag{4c}
$$

where [\(4b](#page-1-1)) constrains the energy consumption of hybrid NOMA. Note that  $\eta$  is a constant and satisfies  $\eta \leq 1$ , which guarantees that the energy consumption of hybrid NOMA cannot exceed that of OMA. [\(4c](#page-1-1)) is considered to ensure the success of decoding  $U_m$ 's signal as stated in Section II.

It can be easily concluded from problem [\(4\)](#page-1-1) that the considered hybrid NOMA is a general form, since both pure NOMA ( $\beta_2 = 0$ ) and OMA ( $\beta_1 = 0$ ) can be treated as special cases of hybrid NOMA.

The optimal solution of problem [\(4\)](#page-1-1) can be obtained in a closed-form, as highlighted in the following lemma.

Lemma 1. *The optimal solution of problem [\(4\)](#page-1-1) can be expressed as follows:*

$$
\beta_1^* = \begin{cases} 0, & \tau_m = 0, \\ \frac{\eta}{2}, & \tau_m > 0 \text{ and } \frac{\tau_m}{\rho_n |h_n^2|} \ge \frac{\eta}{2}, \\ \frac{\tau_m}{\rho_n |h_n^2|}, & \tau_m > 0 \text{ and } \frac{\tau_m}{\rho_n |h_n^2|} < \frac{\eta}{2}, \end{cases}
$$
(5)

*and*  $\beta_2^* = \eta - \beta_1^*$ *.* 

*Proof:* Please refer to Appendix A.

*Remark* 1*.* From the results in Lemma 1, the achievable data rate of the considered hybrid NOMA, denoted by  $R_n^*$ , can be straightforwardly obtained as follows:

• When  $\tau_m = 0$ ,

$$
R_n^* = \log(1 + \eta \rho_n |h_n|^2)
$$
 (6)

For this case,  $\tau_m = 0$  means that  $U_m$  does not have the ability to accommodate inter-user interferences, and hence  $U_n$  is prohibited from transmitting any signal in  $U_m$ 's time slot. Thus,  $U_n$  can only transmit by using its own time slot by using pure OMA. In this case, the data rate achieved by hybrid NOMA equals to that achieved by pure OMA only if  $\eta = 1$ .

• When  $\tau_m > 0$ ,

$$
R_n^* = 2\log(1 + \frac{\eta}{2}\rho_n|h_n|^2),\tag{7}
$$

for 
$$
\frac{\tau_m}{\rho_n|h_n^2|} \ge \frac{\eta}{2}
$$
, and  
\n $R_n^* = \log(1 + \tau_m) + \log(1 + \eta \rho_n |h_n|^2 - \tau_m)$ , (8)

for  $\frac{\tau_m}{\rho_n|h_n^2|} < \frac{\eta}{2}$  $\frac{\eta}{2}$ . For this case,  $\tau_m > 0$  means that  $U_m$ has the ability to accommodate some interferences from other users. An interesting and important observation is: when  $\tau_m > 0$ ,  $U_n$  always prefer to occupying  $U_m$ 's slot to transmit partially, i.e.,  $\beta_1^* > 0$ . In other words, hybrid NOMA achieves a higher data rate than pure NOMA and pure OMA when  $\tau_m > 0$ .

<span id="page-1-1"></span>Next, we will show the superior performance of hybrid NOMA in terms of energy efficiency compared to OMA. From Lemma 1, it can be found that the energy consumption of the considered hybrid NOMA scheme is  $\eta T \rho_n$  ( $0 < \eta \leq 1$ ), which can be lower than  $T\rho_n$  of the pure OMA scheme for  $\eta < 1$ . Thus, an interesting question is whether hybrid NOMA can achieve a higher data rate with  $\eta$  < 1 compared to a pure OMA scheme which uses full transmit power and has an achievable data rate as shown in (1). By comparing  $R_n^*$  and  $R_n^{\text{OMA}}$  with some algebraic manipulations, the following corollary can be obtained.

Corollary 1. For a given  $\eta$ , the maximum achievable data rate of hybrid NOMA is strictly larger than that of OMA which utilizes full transmit power  $\rho_n$ , i.e.,  $R_n^* > R_n^{\text{OMA}}$ , if and only if:

$$
\frac{\tau_m}{\rho_n|h_n^2|} \ge \frac{\eta}{2}, \text{ and } |h_n|^2 > \frac{4(1-\eta)}{\eta^2 \rho_n},\tag{9}
$$

or

$$
0 < \frac{\tau_m}{\rho_n |h_n^2|} < \frac{\eta}{2}, \tau_m \ge \frac{1}{\eta} - 1, \text{ and } |h_n|^2 > \frac{\tau_m^2}{\rho_n \left( \eta + \tau_m \eta - 1 \right)}.\tag{10}
$$

*Remark* 2. When  $\eta = 1$ , it can be straightforwardly observed that  $R_n^* > R_n^{\text{OMA}}$  always holds, as long as  $\tau_m > 0$ .

Corollary 1 gives the conditions under which hybrid NOMA can achieve a higher instantaneous data rate than pure NOMA by consuming less energy. Furthermore, it is interesting to investigate how likely these conditions occur by considering the randomness of the channel gains. Particularly, define the following probability:

$$
P_n^w = \Pr\left(R_n^* \le R_n^{\text{OMA}}\right). \tag{11}
$$

The expression for  $P_n^w$  can be obtained as highlighted in the following lemma.

**Lemma 2.** *For a given*  $\eta$ ,  $0 < \eta \leq 1$ *, the probability that*  $R_n^* \leq R_n^{OMA}$  *can be expressed as:* 

$$
P_n^w = 1 - e^{-\frac{(2-\eta)\epsilon_0}{\eta \rho_m} - \frac{4(1-\eta)}{\eta^2 \rho_n}} - \int_{\frac{\epsilon_0}{\eta \rho_m}}^{\frac{(2-\eta)\epsilon_0}{\eta \rho_m}} e^{-y} e^{-\frac{(\frac{\rho_m}{\epsilon_0}y - 1)^2}{\rho_n \left(\frac{\eta \rho_m}{\epsilon_0}y - 1\right)}} dy \tag{12}
$$

*Proof:* Please refer to Appendix B.

*Remark* 3. By taking derivatives of  $P_n^w$  with respect to  $\rho_n$ and  $\rho_m$ , respectively, it can be found that  $P_n^w$  decreases with  $\rho_n$  and  $\rho_m$ , respectively.

Based on Lemma 2, the following Lemma can be obtained, which characterizes the asymptotic performance of  $P_n^w$  in the high SNR regime.

**Lemma 3.** For a given  $\eta$ ,  $0 < \eta \leq 1$ , when  $\rho_n \to \infty$ *and*  $\rho_m \to \infty$ , the probability that  $R_n^* \leq R_n^{OMA}$  can be *approximated as follows:*

$$
P_n^w \approx \frac{\epsilon_0}{\eta \rho_m} + \frac{4(1 - \eta)}{\eta^2 \rho_n} \tag{13}
$$

*Proof:* Please refer to Appendix C.

<span id="page-2-3"></span>*Remark* 4*.* From Lemma 3, it can be straightforwardly observed that  $P_n^w$  can approach zero when  $\rho_n \to \infty$  and  $\rho_m \to \infty$ , for any given  $\eta$ ,  $0 < \eta \leq 1$ . The importance of this observation is: even with less energy consumption (when  $\eta$  < 1), hybrid NOMA can almost surely achieve a higher instantaneous data rate than pure OMA in the high SNR regime, which indicates the superior energy efficiency of hybrid NOMA.

<span id="page-2-4"></span>*Remark* 5. Note that  $P_n^w$  can approach zero only when both  $\rho_n$  and  $\rho_m$  becomes sufficiently large. Specifically, by following the similar methods in Appendix C, it can be proved that: when  $\rho_n$  or  $\rho_m$  is a constant, while the other goes infinity,  $P_n^w$  approaches a constant, as listed in the following:

• when  $\rho_n$  is a constant and  $\rho_m \to \infty$ ,  $P_n^w$  can be approximated as:

$$
P_n^w \approx 1 - e^{-\frac{4(1-\eta)}{\eta^2 \rho_n}}.
$$
 (14)

• when  $\rho_m$  is a constant and  $\rho_n \to \infty$ ,  $P_n^w$  can be approximated as:

$$
P_n^w \approx 1 - e^{-\frac{\epsilon_0}{\eta \rho_m}}.\tag{15}
$$

It is interesting in [\(15\)](#page-2-0) that, when  $\rho_m$  is a constant  $P_n^w$ is limited not only by  $\rho_m$ , but also by  $\eta$ .

<span id="page-2-1"></span>

<span id="page-2-2"></span>Fig. 2: The probability of the event that  $R_n^* \le R_n^{\text{OMA}}$ .  $\eta = 0.8$ ,  $\rho_n = \rho_m$ .

Fig. 3: The probability of the event that  $R_n^* \le R_n^{\text{OMA}}$ .  $\eta = 0.8$ ,  $R_0 = 1$  BPCU.

#### IV. NUMERICAL RESULTS

<span id="page-2-5"></span>In this section, numerical results are presented to verify the developed analytical results and also demonstrate the superior performance of the proposed hybrid NOMA scheme.

Fig. [2](#page-2-1) shows the probability of the event that  $R_n^* \le R_n^{\text{OMA}}$ , i.e.,  $P_n^w$ . Note that "BPCU" stands for "bits per channel use". It is worth pointing out that the energy consumption of the hybrid NOMA is  $T\eta\rho_n$ , while the energy consumption of the pure OMA is  $T\rho_n$ . The analytical results are based on Lemma 2, and the approximations are based on Lemma 3. From the figure, it can be seen that the analytical results are in perfect agreement with the simulations, which verifies the accuracy of the analysis. It can also be seen that the curves of the approximated results overlap with those of the simulation results. Therefore, the approximations are accurate in the high SNR regime.

Fig. [3](#page-2-2) shows how  $P_n^w$  varies with respect to  $\rho_n$  and  $\rho_m$ , which is based on Lemma 2. From the figure, it can be observed that when both  $\rho_n$  and  $\rho_m$  are sufficiently large,  $P_n^w$ approaches zero, which is consistent with the conclusions of Remark [4.](#page-2-3) From Fig. [3,](#page-2-2) it can also be seen that for fixed  $\rho_n$ ,  $P_n^w$  decreases as  $\rho_m$  increases. However, there's a saturation for  $P_n^w$ , indicating that if  $\rho_n$  is bounded, further increasing  $\rho_m$ won't bring  $P_n^w$  to zero. Similar conclusions can be observed when  $\rho_n$  is fixed. These observations are consistent with the statement discussed in Remark [5.](#page-2-4)

<span id="page-2-0"></span>Fig. [4](#page-3-0) compares the ergodic rates achieved by hybrid NOMA and pure OMA. Note that the ergodic data rate is

<span id="page-3-0"></span>

Fig. 4: Ergodic data rate achieved by hybrid NOMA and pure OMA.  $\rho_n = \rho_m$ ,  $R_0 = 1$  BPCU.

obtained by averaging over  $10^7$  random channel realizations. From the figure, it can be observed that when  $\eta$  < 1, the ergodic data rate achieved by hybrid NOMA is lower than that of pure OMA at low SNRs. However, as  $\rho_n$  increases, the ergodic data rate achieved by hybrid NOMA can outperform that of pure OMA, and the gap increases with  $\rho_n$ . Thus, it can be concluded that hybrid NOMA can achieve a higher ergodic data rate while consuming less power than pure OMA in the high SNR regime.

#### V. CONCLUSIONS

In this paper, the achievable data rate of hybrid NOMA has been obtained by optimizing the power allocation. The conditions under which hybrid NOMA can achieve a higher instantaneous data rate with less power consumption compared to pure OMA have been established. Furthermore, it has been proved that the probability that hybrid NOMA can achieve a higher instantaneous data rate with less power consumption (for any given  $\eta$  < 1) compared to OMA approaches one in the high SNR regime. Numerical results are also provided to show that the ergodic data rate achieved by hybrid NOMA with lower energy consumption is greater than that of pure OMA.

### APPENDIX A PROOF FOR LEMMA 1

It is straightforward to prove that the equality in constraint [\(4b](#page-1-1)) must hold for the optimal solution of problem [\(4\)](#page-1-1), i.e.,  $\beta_2 = \eta - \beta_1$ . Thus, the primal problem is equivalent to the following:

$$
\max_{\beta_1} \log (1 + \beta_1 \rho_n |h_n|^2) + \log (1 + (\eta - \beta_1)\rho_n |h_n|^2)
$$
  
(16a)  
s.t. (4c).

Then, it can be observed that finding the optimal  $\beta_1$  is equivalent to solving the following optimization problem:

$$
\max_{\beta_1} - \rho_n^2 |h_n|^4 \beta_1^2 + \eta \rho_n^2 |h_n|^4 \beta_1 + 1 + \eta \rho_n |h_n|^2 \qquad (17a)
$$
  
s.t. (4c).

Note that the objective function of problem [\(17\)](#page-3-1) is a quadratic function of  $\beta_1$ , and the optimal solution for [\(17a](#page-3-1)) without any constraint is  $\frac{\eta}{2}$ . Therefore, the optimal solution of the primal problem can be determined by finding the feasible solution in [\(4c](#page-1-1)) which is nearest to  $\frac{\eta}{2}$ , and the proof for Lemma 1 can be complete.

# APPENDIX B PROOF FOR LEMMA 2

By considering the conditions shown in Corollary 1,  $P_n^w$ can be written as follows:

$$
P_n^w = \underbrace{\Pr(\tau_m = 0)}_{P_1} + \underbrace{\Pr(\tau_m > 0, \frac{\tau_m}{\rho_n |h_n|^2} \ge \frac{\eta}{2})}_{P_2} \tag{18}
$$
\n
$$
+ \underbrace{\Pr(\tau_m > 0, \frac{\tau_m}{\rho_n |h_n|^2} < \frac{\eta}{2}, \tau_m \le \frac{1}{\eta} - 1)}_{P_{3,1}}
$$
\n
$$
+ \Pr(\tau_m > 0, \frac{\tau_m}{\rho_n |h_n|^2} < \frac{\eta}{2}, \tau_m > \frac{1}{\eta} - 1,
$$
\n
$$
\underbrace{|h_n|^2 \le \frac{\tau_m^2}{\rho_n (\eta + \tau_m \eta - 1)}}_{P_{3,2}}.
$$

Thus, the remaining task is to calculate the expressions for  $P_1$ ,  $P_2$ ,  $P_{3,1}$  and  $P_{3,2}$ .

The expression for  $P_1$  can be obtained as follows:

$$
P_1 = \Pr\left(|h_m|^2 \le \frac{\epsilon_0}{\rho_m}\right) = \int_0^{\frac{\epsilon_0}{\rho_m}} e^{-x} dx = 1 - e^{-\frac{\epsilon_0}{\rho_m}}. (19)
$$
  
Be can be rewritten as

 $P_2$  can be rewritten as

$$
P_2 = \Pr\left(|h_m|^2 > \frac{\epsilon_0}{\rho_m}, |h_n|^2 \le \min\left\{\frac{2\tau_m}{\eta \rho_n}, \frac{4(1-\eta)}{\eta^2 \rho_n}\right\}\right) \tag{20}
$$
\n
$$
= \Pr\left(|h_m|^2 > \frac{\epsilon_0(2-\eta)}{\rho_m \eta}, |h_n|^2 \le \frac{4(1-\eta)}{\eta^2 \rho_n}\right) +
$$
\n
$$
\Pr\left(\frac{\epsilon_0}{\rho_m} < |h_m|^2 \le \frac{\epsilon_0(2-\eta)}{\rho_m \eta}, |h_n|^2 \le \frac{2\tau_m}{\eta \rho_n}\right)
$$
\n
$$
P_{2,2}
$$

By noting that the probability density functions (PDF) for  $|h_n|^2$  and  $|h_m|^2$  are

$$
f_{|h_n|^2}(x) = e^{-x}, f_{|h_m|^2}(y) = e^{-y}, \tag{21}
$$

 $P_{2,1}$  and  $P_{2,2}$  can be obtained as follows:

$$
P_{2,1} = \int_{\frac{\epsilon_0 (2-\eta)}{\rho_m \eta}}^{+\infty} \int_0^{\frac{4(1-\eta)}{\eta^2 \rho_n}} e^{-x} e^{-y} dx dy
$$
 (22)  
=  $e^{-\frac{\epsilon_0 (2-\eta)}{\rho_m \eta}} \left(1 - e^{-\frac{4(1-\eta)}{\eta^2 \rho_n}}\right)$ 

<span id="page-3-1"></span>
$$
P_{2,2} = \int_{\frac{\epsilon_0}{\rho_m}}^{\frac{\epsilon_0(2-\eta)}{\rho_m \eta}} \int_0^{\frac{2\rho_m y - 2\epsilon_0}{\eta \rho_n \epsilon_0}} e^{-x} e^{-y} dx dy
$$
(23)  
=  $e^{-\frac{\epsilon_0}{\rho_m}} - e^{-\frac{\epsilon_0(2-\eta)}{\rho_m \eta}}$   
 $- \frac{\eta \rho_n \epsilon_0 e^{\frac{2}{\eta \rho_n}}}{2\rho_m + \eta \rho_n \epsilon_0} \left( e^{-\frac{2}{\eta \rho_n} - \frac{\epsilon_0}{\rho_m}} - e^{-\frac{(2-\eta)\epsilon_0}{\eta \rho_m} - \frac{4-2\eta}{\eta^2 \rho_n}} \right)$ 

Thus, the expression for  $P_2$  can be obtained by summing  $P_{2,1}$ and  $P_{2,2}$ . and

 $P_{3,1}$  can calculated as follows:

$$
P_{3,1} = \Pr\left(\frac{\epsilon_0}{\rho_m} < |h_m|^2 \le \frac{\epsilon_0}{\eta \rho_m}, |h_n|^2 > \frac{2\tau_m}{\eta \rho_n}\right) \tag{24}
$$
\n
$$
= \int_{\frac{\epsilon_0}{\rho_m}}^{\frac{\epsilon_0}{\eta \rho_m}} \int_{\frac{2\rho_m y - 2\epsilon_0}{\eta \rho_n \epsilon_0}}^{\frac{+\infty}{\rho_m}} e^{-x} e^{-y} dx dy
$$
\n
$$
= \frac{\eta \rho_n \epsilon_0 e^{\frac{2}{\eta \rho_n}}}{2\rho_m + \eta \rho_n \epsilon_0} \left(e^{-\frac{2}{\eta \rho_n} - \frac{\epsilon_0}{\rho_m}} - e^{-\frac{2}{\eta^2 \rho_n} - \frac{\epsilon_0}{\eta \rho_m}}\right)
$$

By noting that  $\eta \leq 1$ ,  $P_{3,2}$  can rewritten as follows:

$$
P_{3,2} = \Pr\left(|h_m|^2 > \frac{\epsilon_0}{\eta \rho_m}, |h_n|^2 > \frac{2\tau_m}{\eta \rho_n},\right\}
$$
\n
$$
|h_n|^2 \le \frac{\tau_m^2}{\rho_n(\eta + \tau_m \eta - 1)},\tag{25}
$$

It is worth pointing out that there is an implicit condition in  $(25)$  that

$$
\frac{2\tau_m}{\eta \rho_n} < \frac{\tau_m^2}{\rho_n(\eta + \tau_m \eta - 1)}.\tag{26}
$$

which can be simplified to  $|h_m|^2 < \frac{(2-\eta)\epsilon_0}{n\rho_m}$  $\frac{(-\eta)\epsilon_0}{\eta\rho_m}$ . Thus,  $P_{3,2}$  should be expressed as:

$$
P_{3,2} = \Pr\left(\frac{\epsilon_0}{\eta \rho_m} < |h_m|^2 < \frac{(2-\eta)\epsilon_0}{\eta \rho_m}, \frac{(27)\epsilon_0}{\eta \rho_m} < |h_n|^2 \le \frac{\tau_m^2}{\rho_n(\eta + \tau_m \eta - 1)}\right)
$$

By taking the PDFs for  $|h_n|^2$  and  $|h_m|^2$  into the above equation,  $P_{3,2}$  can be expressed as:

$$
P_{3,2} = \int_{\frac{\epsilon_0}{\eta_{\rho_m}}}^{\frac{(2-\eta)\epsilon_0}{\eta_{\rho_m}}} \int_{\frac{2\tau_m}{\eta_{\rho_n}}}^{\frac{\tau_m^2}{\rho_n(\eta + \tau_m \eta - 1)}} e^{-x} e^{-y} dx dy \qquad (28)
$$
  

$$
= \int_{\frac{\epsilon_0}{\eta_{\rho_m}}}^{\frac{(2-\eta)\epsilon_0}{\eta_{\rho_m}}} e^{-y} e^{-\frac{2\rho_m y - 2\epsilon_0}{\eta_{\rho_n}\epsilon_0}} dy
$$
  

$$
- \int_{\frac{\epsilon_0}{\eta_{\rho_m}}}^{\frac{(2-\eta)\epsilon_0}{\eta_{\rho_m}}} e^{-y} e^{-\frac{(\frac{\rho_m}{\epsilon_0}y - 1)^2}{\rho_n(\frac{\eta_{\rho_m}}{\epsilon_0}y - 1)}} dy
$$
  

$$
= \frac{\eta \rho_n \epsilon_0 e^{\frac{2}{\eta_{\rho_m}}}}{2\rho_m + \eta \rho_n \epsilon_0} \left( e^{-\frac{2}{\eta_{\rho_m}^2 - \frac{\epsilon_0}{\eta_{\rho_m}}} - e^{-\frac{(2-\eta)\epsilon_0}{\eta_{\rho_m}} - \frac{4-2\eta}{\eta_{\rho_m}}} \right)
$$
  

$$
- \int_{\frac{\epsilon_0}{\eta_{\rho_m}}}^{\frac{(2-\eta)\epsilon_0}{\eta_{\rho_m}}} e^{-y} e^{-\frac{(\frac{\rho_m}{\epsilon_0}y - 1)^2}{\rho_n(\frac{\eta_{\rho_m}}{\epsilon_0}y - 1)}} dy
$$

By summing up  $P_1$ ,  $P_2$ ,  $P_{3,1}$  and  $P_{3,2}$  and making some algebraic manipulations, the expression for  $P_n^w$  can be obtained and the proof is complete.

# APPENDIX C PROOF FOR LEMMA 3

Denote  $P_n^w$  by  $P_n^w = G + Q$ , where

$$
G = 1 - e^{-\frac{(2-\eta)\epsilon_0}{\eta \rho_m} - \frac{4(1-\eta)}{\eta^2 \rho_n}},\tag{29}
$$

$$
Q = -\int_{\frac{\epsilon_0}{\eta_{\rho_m}}}^{\frac{(2-\eta)\epsilon_0}{\eta_{\rho_m}}} e^{-y} e^{-\frac{(\frac{\rho_m}{\epsilon_0}y-1)^2}{\rho_n(\frac{\eta_{\rho_m}}{\epsilon_0}y-1)}} dy.
$$
 (30)

By applying the Taylor series  $e^{-x} \approx 1 - x$  ( $x \to 0$ ), G can be approximated as follows:

$$
G \approx 1 - \left(1 - \frac{(2 - \eta)\epsilon_0}{\eta \rho_m}\right) \left(1 - \frac{4(1 - \eta)}{\eta^2 \rho_n}\right) \tag{31}
$$

$$
= \frac{(2 - \eta)\epsilon_0}{\eta \rho_m} + \frac{4(1 - \eta)}{\eta^2 \rho_n} - \frac{4(1 - \eta)(2 - \eta)\epsilon_0}{\eta^3 \rho_m \rho_n}
$$

$$
\overset{(a)}{\approx} \frac{(2 - \eta)\epsilon_0}{\eta \rho_m} + \frac{4(1 - \eta)}{\eta^2 \rho_n},
$$

<span id="page-4-10"></span>where the step (a) follows from the fact that the last term is a higher order infinitesimal quantity compared to the other two terms and hence can be neglected.

Let  $t = \frac{\rho_m}{\epsilon_0} y$ , Q can be written as

$$
Q = -\int_{\frac{1}{\eta}}^{\frac{2-\eta}{\eta}} \frac{\epsilon_0}{\rho_m} e^{-\frac{\epsilon_0}{\rho_m}t} e^{-\frac{(t-1)^2}{\rho_n(\eta t-1)}} dt.
$$
 (32)

By taking Taylor series,  $Q$  can be approximated as follows:

$$
Q \approx -\int_{\frac{1}{\eta}}^{\frac{2-\eta}{\eta}} \frac{\epsilon_0}{\rho_m} \left(1 - \frac{\epsilon_0}{\rho_m} t\right) \left(1 - \frac{(t-1)^2}{\rho_n(\eta t - 1)}\right) dt \quad (33)
$$

$$
\approx -\int_{\frac{1}{\eta}}^{\frac{2-\eta}{\eta}} \frac{\epsilon_0}{\rho_m} dt = -\frac{(1-\eta)\epsilon_0}{\eta \rho_m}
$$

Thus, the approximate for  $P_n^w$  in [\(13\)](#page-2-5) can be obtained and the proof is complete.
