(Received xx; revised xx; accepted xx)

Internal waves in a two-layer fluid with rotation are considered within the framework of Helfrich's f-plane extension of the Miyata–Choi–Camassa (MCC) model. Within the scope of this model, we develop an asymptotic procedure which allows us to obtain a description of a large class of uni-directional waves leading to the Ostrovsky equation and allowing for the presence of shear inertial oscillations and barotropic transport. Importantly, unlike the conventional derivations leading to the Ostrovsky equation, the constructed solutions do not impose the zero-mean constraint on the initial conditions for any variable in the problem formulation. Using the constructed solutions, we model the evolution of quasi-periodic initial conditions close to the cnoidal wave solutions of the Korteweg–de Vries (KdV) equation but having a local amplitude and/or periodicity defect, and show that such initial conditions can lead to the emergence of bursts of large internal waves and shear currents. As a by-product of our study, we show that cnoidal waves with periodicity defects discussed in this work are weak solutions of the KdV equation and, being smoothed in numerical simulations, they behave as long-lived approximate travelling waves of the KdV equation, with the associated bursts being solely due to the effect of rotation.

**Key words:** Internal waves, Ostrovsky equation, weak solutions of the KdV equation, rogue waves

#### **1. Introduction**

The Korteweg–de Vries- and Ostrovsky-type family of models plays an important role in understanding the behaviour of long nonlinear internal waves commonly observed in coastal seas, narrow straits and river-sea interaction areas (see [Grimshaw et al.](#page-30-0) [1998;](#page-30-0) [Helfrich and](#page-30-1) [Melville](#page-30-1) [2006;](#page-30-1) [Bona et al.](#page-29-0) [2008;](#page-29-0) [Ostrovsky et al.](#page-31-0) [2015;](#page-31-0) [Khusnutdinova and Zhang](#page-30-2) [2016;](#page-30-2) [Ostrovsky et al.](#page-31-1) [2024,](#page-31-1) and references therein). The Ostrovsky equation [\(Ostrovsky](#page-31-2) [1978\)](#page-31-2)

<span id="page-0-0"></span>
$$
(A_t + vAA_{\xi} + \lambda A_{\xi\xi\xi})_{\xi} = \gamma A \tag{1.1}
$$

is a rotationally modified extension of the integrable Korteweg-de Vries (KdV) equation [\(Boussinesq](#page-29-1) [1871;](#page-29-1) [Korteweg and de Vries](#page-30-3) [1895;](#page-30-3) [Gardner et al.](#page-30-4) [1967\)](#page-30-4), accounting for the

**Abstract must not spill onto p.2**

leading order balance of weak nonlinear, dispersive and rotational effects. In the general setting of a density stratified fluid described by the Euler equations with boundary conditions appropriate for oceanic applications, equation [\(1.1\)](#page-0-0) is written for the amplitude  $A(\xi, T)$  of a single plane internal mode  $\phi(z)$  in a reference frame moving with the linear long wave speed  $c_0$ . In physical variables where the bottom is at  $z = -h$  and unperturbed surface is at  $z = 0$ , the modal equations have the form

$$
(\rho_0 W^2 \phi_z)_z + \rho_0 N^2 \phi = 0, \qquad (1.2)
$$

$$
\phi = 0
$$
 at  $z = -h$ , and  $W^2 \phi_z = g \phi$  at  $z = 0$ . (1.3)

Here  $\rho_0(z)$  is the stable background density profile,  $N^2 = -g\rho_{0z}/\rho_0$ ,  $W = c_0 - u_0$ , where  $u_0(z)$  is the background shear flow supported by a body force, and it is assumed that there are no critical levels, that is  $W \neq 0$  for any z in the flow domain. The nonlinear, dispersive and rotational coefficients  $v, \lambda$  and  $\gamma$ , respectively, are given by

$$
Iv = 3 \int_{-h}^{0} \rho_0 W^2 \phi_z^3 dz, \quad I\lambda = \int_{-h}^{0} \rho_0 W^2 \phi^2 dz, \quad I\gamma = f^2 \int_{-h}^{0} \rho_0 \Phi \phi_z dz, \quad (1.4)
$$

where

$$
I = 2 \int_{-h}^{0} \rho_0 W \phi_z^2 dz, \quad \rho_0 W \Phi = \rho_0 W \phi_z - (\rho_0 u_0)_z \phi, \tag{1.5}
$$

and  $f$  is the Coriolis parameter (a reduction of the bi-modal system derived in [Alias et al.](#page-29-2) [2013\)](#page-29-2). Note that when there is no shear flow, that is  $u_0(z) \equiv 0$ , then  $\Phi \equiv \phi_z$  and  $\gamma = f^2/2c$ ; in this case  $\lambda \gamma > 0$ , but sufficiently strong shear near a pycnocline may lead to a situation where  $\beta \gamma < 0$  [\(Alias et al.](#page-29-3) [2014\)](#page-29-3).

The Ostrovsky equation became a paradigm forming model for studying the effects of rotation on the evolution of internal waves with the natural initial conditions in the form of KdV solitons (see [Grimshaw et al.](#page-30-5) [2013;](#page-30-5) [Stepanyants](#page-31-3) [2020;](#page-31-3) [Ostrovsky et al.](#page-31-1) [2024](#page-31-1) and references therein) and cnoidal waves, with an emphasis on modulational instability (see [Whitfield and Johnson](#page-31-4) [\(2017\)](#page-31-4) and references therein), as well as the related qualitative analysis of the long-time asymptotics of strongly-interacting internal modes described by solutions of coupled Ostrovsky equations [\(Alias et al.](#page-29-3) [2014\)](#page-29-3). One of the aims of our current study is to extend the modelling to situations when the initial conditions are close to a cnoidal wave (approximately a chain of KdV solitons), but they are not perfectly periodic, and rather have some defects within the computational domain (hence, they can be viewed as being quasi-periodic). The motivation for that stems from the observational data of the type shown in Figure [1,](#page-2-0) where we can see formation of a wavetrain of internal solitary waves close to an imperfect cnoidal wave. Indeed, given that the waves generally propagate in variable environment, quasi-periodic initial conditions seem to be a more natural choice than a single (pure or only slowly modulated) cnoidal wave. Recently, there appeared renewed interest in the possibility of generating rogue waves and breathers by various localised perturbations of cnoidal waves both in integrable and non-integrable settings (see Kuznetsov  $\&$  Mikhailov [1975;](#page-30-6) [Onorato et al.](#page-31-5) [2013;](#page-31-5) [Chabchoub et al.](#page-29-4) [2013;](#page-29-4) [Kedziora et al.](#page-30-7) [2014;](#page-30-7) [Maiden and Hoefer](#page-30-8) [2016;](#page-30-8) [Chabchoub et al.](#page-29-5) [2021;](#page-29-5) [He et al.](#page-30-9) [2022;](#page-30-9) [Bertola et al.](#page-29-6) [2023;](#page-29-6) [Grava et al.](#page-30-10) [2023;](#page-30-10) [Hoefer](#page-30-11) [et al.](#page-30-11) [2023;](#page-30-11) [Mao et al.](#page-30-12) [2023;](#page-30-12) [Chandramuli et al.](#page-29-7) [2024,](#page-29-7) and references therein), among other possible mechanisms (e.g. [Kharif et al.](#page-30-13) [2009;](#page-30-13) [Zakharov](#page-31-6) [2009;](#page-31-6) [Pelinovsky and Slunyaev](#page-31-7) [2016;](#page-31-7) [Bokaeeyan et al.](#page-29-8) [2019;](#page-29-8) [Choi et al.](#page-29-9) [2022;](#page-29-9) [Slunyaev and Shrira](#page-31-8) [2023;](#page-31-8) [Agafontsev et al.](#page-29-10) [2024;](#page-29-10) [Congy et al.](#page-29-11) [2024;](#page-29-11) [Flamarion et al.](#page-29-12) [2024;](#page-29-12) [Slunyaev](#page-31-9) [2024,](#page-31-9) and references therein). [O](#page-29-10)ur study extends the former line of research by adding the effect of rotation.

Unlike the KdV equation, the Ostrovsky equation has a constraint on the mean value of

<span id="page-2-0"></span>

Figure 1: The first 1.7 hours of the colour contour time series of temperature profiles off Northern Oregon from the surface to 35m depth. The figure is adapted from [Stanton and](#page-31-10)<br>
Ostrovsky (1998) **day period. The 10 'C span color contour scale is shown the right**  Ostrovsky [\(1998\)](#page-31-10).

its regular solutions. For example, for periodic solutions on the interval [−L, L], any regular solution should have zero mean:

$$
\int_{-L}^{L} A \, d\xi = 0. \tag{1.6}
$$

Additional constraints appear when solutions are considered in the class of functions vanishing at invinity (Benilov 1992). The existing derivations of the Ostrovsky equation restriction on the choice of initial conditions of the Cauchy problem for the parent system generalise the construction of weakly-nonlinear solutions leading to the Ostrovsky equation generalise the construction of weakly-nonlinear solutions leading to the Ostrovsky equation **A 15-minute average profile of density and the natural**  in such a way that the zero-mean contradiction is avoided. Indeed, this has been previously done within the scope of the derivation of Ostrovsky-type models in the simpler settings of the Boussinesq-Klein-Gordon and coupled Boussinesq equations [\(Khusnutdinova et al.](#page-30-14) [2014;](#page-30-14) [Khusnutdinova and Tranter](#page-30-15) [2019,](#page-30-15) 2022). In contrast to the previous work, in the fluids **cph at 5m depth. This shallow, strong stratification arises from**  mean values, presenting a significant new challenge, which is addressed in our present paper. **x**  $\frac{1}{2}$  **c**  $\frac{1}{2}$  **displacements**  $\frac{1}{2}$  **displacements**  $\frac{1}{2}$  **displacements**  $\frac{1}{2}$  **d the pycnocline. Following Ostrovsky and Stepanyants (1989), (1) is fully integrable, and has a solution in the form of a solution in the form of a solution in the form of a solitary**  $\alpha$  **solitary**  $\alpha$ from the Euler equations do not allow one to consider the arbitrary initial conditions for the field variables of the parent system, but only those which agree with this constraint. This became known as the "zero-mean contradiction". Hence, another aim of our study is to context the mean-field equations appear to be coupled to equations for deviations from the

Hence, the aim of our study is twofold, and the rest of the paper is organised as follows. In Section 2 we introduce Helfrich's rotation-modified two-layer Miyata–Choi–Camassa (MCC-f) model (Helfrich 2007) and obtain its simpler weakly-nonlinear reduction which is used to develop the subsequent (weakly-nonlinear) derivations of the reduced model (for the If also indicate the same system has been derived and studied). While this setting is simpler<br>[1989,](#page-30-18) where the same system has been derived and studied). While this setting is simpler **time was confined by the sharp pycnocline to a very shallow, 4m**  [t](#page-30-18)han the full Euler equations, our derivations reveal that it retains the key complexity: the mean-field equations are coupled with the equations for the deviations. Therefore, this model derivation of the uni-directional model by considering the simultaneous evolution of mean<br>fields and their deviations. This approach introduces the fest eheroeteristic veriable  $5 - x$ , as the and two slow-time variables  $\tau = \sqrt{\alpha t}$  and  $T = \alpha t$ , rather than just one, where  $\alpha$  is the small dispersion and rotation). We find a way to by-pass the zero-mean contradiction by developing flust asymptotic expansions of bour the mean-field variables and deviation **-15**  provides an appropriate framework for our developments. Next, in Section [3](#page-5-0) we refine the **-25**  simultaneous asymptotic expansions of both the mean-field variables and deviations. Thisoriginal MCC model see Miyata [1988;](#page-31-11) [Choi and Camassa](#page-29-14) [1996,](#page-29-14) [1999,](#page-29-15) but also [Maltseva](#page-30-18) fields and their deviations. This approach introduces the fast characteristic variable  $\xi = x - c_0 t$ amplitude parameter (we assume the maximum balance conditions for the weak nonlinearity,

allows us to construct a more general class of solutions allowing the initial conditions for all fluid variables to have arbitrary (and generally time-dependent) mean values, while the emerging Ostrovsky equations have zero mean by construction. In Section [4](#page-9-0) we use the constructed weakly-nonlinear solution combined with numerical modelling using the Ostrovsky equation in order to investigate the effect of rotation on the evolution of cnoidal waves of the KdV equation close to their solitonic limit and having local amplitude and/or periodicity defects. We begin the section by considering the effect of rotation on simple soliton and cnoidal wave solutions, as well as dark and bright breathers of the KdV equation and contraction and expansion periodicity defects in order to set up the phenomenological framework for the discussion of our main numerical results. The contraction / expansion defects are introduced by extracting a small symmetric piece around the trough an gluing the remaining parts together / by cutting the cnoidal wave at the trough and symmetrically inserting a piece of straight line, respectively, see the first two rows of Figure [17](#page-27-0) in Appendix A. In all cases we take a sufficiently large computational domain and impose the periodic boundary conditions to model the resulting quasi-periodic solutions. We show that, combined with the effect of rotation, initial conditions in the form of cnoidal waves with local defects can lead to bursts of large amplitude internal waves and shear currents. For the generic local defects introduced by adding a localised perturbation, this can be attributed to the formation of a pair of bright and dark breathers and contraction and expansion periodicity defects, with the subsequent effect of rotation. For the pure expansion and contraction defects the bursts do not take place without rotation. In fact, in numerical runs the smoothed counterparts of such initial conditions evolve almost like travelling wave solutions of the KdV equation, for a very long time. We show that this happens because these functions (and some other functions constructed from the known KdV solutions by similar procedures) satisfy all (infinitly many) conservation laws of the KdV equation (see Appendix A). Moreover, a cnoidal wave with an expansion defect has a continuous first derivative, satisfying the Weirstrass-Erdmann corner condition for broken (non-smooth) extremals (e.g. [Fox](#page-30-19) [1954\)](#page-30-19), and it is a weak solution of the KdV equation. The bursts observed in our modelling with pure periodicity defects are then attributed solely to the effect of rotation. Moreover, we show that the effects discussed in the paper are structurally stable with respect to the natural (compatible with the period of the background cnoidal wave) variations in the size of the computational domain. We finish with a discussion in Section [5,](#page-23-0) where we also show an example where a local perturbation of a cnoidal wave of the type considered in our paper has led to the generation of a rogue wave. A pseudospectral scheme used to solve the Ostrovsky equation is discussed in Appendix B.

# <span id="page-3-0"></span>**2. MCC-f model**

We consider the f-plane extension of the MCC model for an inviscid, incompressible twolayer fluid with the rigid lid introduced by [Helfrich](#page-30-17) [\(2007\)](#page-30-17):

$$
h_{it} + (h_i \overline{u}_i)_x = 0,\t\t(2.1)
$$

$$
\overline{u}_{it} + \overline{u}_{i}\overline{u}_{ix} - f\overline{v}_{i} = -g\eta_{x} + \frac{1}{\rho_{i}}P_{x} + D_{i}, \text{ where}
$$
\n(2.2)

$$
D_i = h_i^{-1} \left\{ \frac{h_i^3}{3} \left[ \overline{u}_{ixt} + \overline{u}_i \overline{u}_{ixx} - (\overline{u}_{ix})^2 \right] \right\}_x,
$$
 (2.3)

$$
(h_i \overline{u}_i)_t + (h_i \overline{u}_i \overline{v}_i)_x + fh_i \overline{u}_i = 0,
$$
\n(2.4)

$$
\overline{v}_{it} + \overline{u}_i \overline{v}_{ix} + f \overline{u}_i = 0. \tag{2.5}
$$

# **Focus on Fluids articles must not exceed this page length**

<span id="page-4-0"></span>

Figure 2: Schematic of a two-layer fluid with rotation in the rigid-lid approximation.

Here,  $h_i$ ,  $\rho_i$  are the layer depths and densities,  $\overline{u}_i$ ,  $\overline{v}_i$  denote the depth-averaged over each layer horizontal velocities in the x and y directions with  $i = 1$  and 2 referring to the upper and  $F_{\text{interface}}$ . The subscripts *t* and *x* denote partial derivatives. In the absence of motion  $h_1 = h_0$ lower layers, respectively;  $f$  is the Coriolis parameter,  $g$  is gravity,  $P$  is the pressure at the and  $h_1 + h_2 = H$  (total depth) (see Figure [2\)](#page-4-0).

In the Boussinesq approximation  $\left(\frac{\rho_2-\rho_1}{\rho_1} \ll 1\right)$ , the equations can be simplified by eliminating  $P_x$ . Using  $\sqrt{g'H}$ , *H*, *l* and  $l/\sqrt{g'H}$  to non-dimensionalise  $(u_i, v_i)$ ,  $h_i$ , *x* and *t*, respectively, and changing the variables to  $s = \overline{u}_2 - \overline{u}_1$ ,  $v = \overline{v}_2 - \overline{v}_1$ ,  $h_2 = 1 - h_1$ ,  $U = h_1 \overline{u}_1 + h_2 \overline{u}_2$ and  $V = \overline{v}_1 h_1 + \overline{v}_2 h_2$  with the barotropic transport in x direction  $U = F(t) \neq 0$  in general, **E**(*k*) is the complete elliptic integral of the second kind, and the second kind, and the *τ* we obtain

$$
\eta_t + (c_0^2 s + \sigma s \eta - s \eta^2 + F \eta)_x = 0,
$$
\n(2.6)

$$
s_t + (\frac{\sigma}{2}s^2 - s^2\eta + \eta + Fs)_x - \tilde{\gamma}v = \tilde{\beta}(D_2 - D_1),
$$
 (2.7)

$$
v_t + s v \eta_x + \sigma s v_x - 2s \eta v_x + F v_x + s V_x + \tilde{\gamma} s = 0,
$$
\n(2.8)

$$
V_t + (c_0^2 sv + \sigma sv\eta - sv\eta^2 + FV)_x + \tilde{\gamma}F = 0,
$$
\n(2.9)

 $\mu_R$ where  $\sigma = 2h_1 - 1$ ,  $\tilde{\gamma} = l/L_R$ ,  $L_R = \sqrt{g'H}/f$ ,  $g' = g\Delta\rho/\rho_1$ ,  $\tilde{\beta} = (H/l)^2$ .

Next, we consider the Ostrovsky equation regime and assume that  $\tilde{\beta} = O(\alpha)$  and  $\tilde{\gamma} = (1/2)$  $O(\alpha^{1/2})$ , where  $\alpha$  is the small amplitude parameter and scale  $\tilde{\beta} = \alpha \beta$ ,  $\tilde{\gamma} = \sqrt{\alpha \gamma}$ , where  $\beta, \gamma = O(1)$ . Then, considering the asymptotic expansions

$$
(\eta, s, v, V) = \alpha(\eta, s, v, V)^{(1)} + \alpha^2(\eta, s, v, V)^{(2)} + O(\alpha^3),
$$
\n(2.10)

<span id="page-4-1"></span>
$$
F = \alpha F^{(1)} + \alpha^2 F^{(2)} + O(\alpha^3),\tag{2.11}
$$

and dropping the terms of  $O(\alpha^3)$  (not used in our subsequent derivations), gives the simpler weakly-nonlinear equations

$$
\eta_t + c_0^2 s_x = -\alpha (\sigma s \eta + F \eta)_x,\tag{2.12}
$$

$$
s_t + \eta_x = \sqrt{\alpha} \gamma v - \alpha (\sigma s s_x + F s_x - \frac{\beta c_0^2}{3} s_{xxt}),
$$
\n(2.13)

<span id="page-4-2"></span>
$$
v_t = -\sqrt{\alpha}\gamma s - \alpha(\sigma s v_x + F v_x + s V_x),\tag{2.14}
$$

$$
V_t = -\sqrt{\alpha}\gamma F - \alpha (c_0^2 s v + F V)_x. \tag{2.15}
$$

For  $F = 0$ , the equations reduce to the model derived by [Helfrich](#page-30-17) [\(2007\)](#page-30-17); [Gerkema](#page-30-20) [\(1996\)](#page-30-20).

We consider the periodic solutions on the interval  $[-L, L]$  (a typical setting for numerical runs using pseudospectral methods). Alongside with the equations  $(2.12)$ – $(2.15)$  we will consider the equations for the evolving mean fields by averaging the system with respect to  $x$  over this interval and denoting the mean values by hats:

$$
\hat{\eta}_t = 0,\tag{2.16}
$$

$$
\hat{s}_t = \sqrt{\alpha} \gamma \hat{v},\tag{2.17}
$$

<span id="page-5-1"></span>
$$
\hat{v}_t = -\sqrt{\alpha}\gamma \hat{s} - \alpha \frac{1}{2L} \int_{-L}^{L} (\sigma s v_x + F v_x + s V_x) dx,
$$
\n(2.18)

<span id="page-5-2"></span>
$$
\hat{V}_t = -\sqrt{\alpha} \gamma F. \tag{2.19}
$$

Here, the mean fields are generally time-dependent. Hence, the equations for the evolving mean values and deviations from the mean values are generally coupled because of the integral term in the equation [\(2.18\)](#page-5-1). This significantly differs from our previous derivations of Ostrovsky-type equations free from zero-mean contradiction within the scope of Boussinesq-Klein-Gordon equation [\(Khusnutdinova et al.](#page-30-14) [2014;](#page-30-14) [Khusnutdinova and Tranter](#page-30-15) [2019\)](#page-30-15) and coupled Boussinesq equations [\(Khusnutdinova and Tranter](#page-30-16) [2022\)](#page-30-16), where the mean fields were described by independent equations.

### <span id="page-5-0"></span>**3. Weakly-nonlinear uni-directional solution free from zero-mean contradiction**

In this section, we construct a large class of solutions of the system  $(2.12)$ – $(2.19)$  describing uni-directionally propagating waves on top of evolving mean fields by presenting each variable in the form of the sum of its mean value (generally, time-dependent) and deviation from this mean value:

$$
\eta = \hat{\eta} + \tilde{\eta}, \ s = \hat{s} + \tilde{s}, \ v = \hat{v} + \tilde{v}, \ V = \hat{V} + \tilde{V}, \tag{3.1}
$$

where the unknowns  $\hat{\eta}, \hat{s}, \hat{v}, \hat{V}$  and the given function F are assumed to be functions of  $t, \tau =$  $\sqrt{\alpha}t$ ,  $T = \alpha t$ , while the deviations  $\tilde{\eta}$ ,  $\tilde{s}$ ,  $\tilde{v}$ ,  $\tilde{V}$  are assumed to depend on the fast characteristic variable  $\xi = x - c_0 t$ , where  $c_0$  is the linear long-wave speed, and two slow-time variables  $\tau$  and T. Both the averages and deviations from the averages are sought in the form of  $\tau$  and  $\tau$ . Both the averages and deviations from the asymptotic multiple-scale expansions in powers of  $\sqrt{\alpha}$ .

$$
(\hat{\eta}, \hat{s}, \hat{v}, \hat{V}) = (\hat{\eta}, \hat{s}, \hat{v}, \hat{V})^{(0)} + \sqrt{\alpha} (\hat{\eta}, \hat{s}, \hat{v}, \hat{V})^{(1)} + \alpha (\hat{\eta}, \hat{s}, \hat{v}, \hat{V})^{(2)} + O(\alpha^{3/2}), \quad (3.2)
$$

$$
(\tilde{\eta}, \tilde{s}, \tilde{v}, \tilde{V}) = (\tilde{\eta}, \tilde{s}, \tilde{v}, \tilde{V})^{(0)} + \sqrt{\alpha} (\tilde{\eta}, \tilde{s}, \tilde{v}, \tilde{V})^{(1)} + \alpha (\tilde{\eta}, \tilde{s}, \tilde{v}, \tilde{V})^{(2)} + O(\alpha^{3/2}).
$$
 (3.3)

The prescribed function  $F(t)$  defining the barotropic transport in the x direction is also assumed to be given in the form

$$
F = F^{(0)} + \sqrt{\alpha} F^{(1)} + \alpha F^{(2)} + O(\alpha^{3/2}).
$$
\n(3.4)

The average interfacial displacement  $\hat{\eta}$  is a constant, and if  $\hat{\eta}^{(0)} \neq 0$ , then without loss of generality we assume that  $\hat{\eta} = \hat{\eta}^{(0)}$ . If  $\hat{\eta}^{(0)} = 0$ , but  $\hat{\eta}^{(1)} \neq 0$  then without loss of generality  $\widetilde{\eta} = \sqrt{\alpha} \widetilde{\eta}^{(1)}$ , etc. Similarly, if  $F^{(0)} \neq 0$ , then we can assume  $F = F^{(0)}$ , etc.

At  $O(1)$  we obtain the equations

$$
-c_0 \tilde{\eta}^{(0)}_{\xi} + c_0^2 \tilde{s}_{\xi}^{(0)} = 0, \quad \hat{s}_t^{(0)} - c_0 \tilde{s}_{\xi}^{(0)} + \tilde{\eta}_{\xi}^{(0)} = 0,
$$
 (3.5)

$$
\hat{v}_t^{(0)} - c_0 \tilde{v}_\xi^{(0)} = 0, \quad \hat{V}_t^{(0)} - c_0 \tilde{V}_\xi^{(0)} = 0, \quad \hat{s}_t^{(0)} = 0, \quad \hat{v}_t^{(0)} = 0, \quad \hat{V}_t^{(0)} = 0, \quad (3.6)
$$

*Evolution of internal cnoidal waves with local defects in a two-layer fluid with rotation* 7 implying

<span id="page-6-0"></span>
$$
\hat{s}^{(0)} = A^{(0)}(\tau, T), \quad \hat{v}^{(0)} = B^{(0)}(\tau, T), \quad \hat{V}^{(0)} = C^{(0)}(\tau, T), \tag{3.7}
$$

$$
\tilde{s}^{(0)} = \frac{1}{c_0} \tilde{\eta}^{(0)}, \quad \tilde{v}^{(0)} = 0, \quad \tilde{V}^{(0)} = 0.
$$
\n(3.8)

Here, the functions  $(A, B, C)^{(0)}$  are arbitrary functions of their variables, and we have used that all deviations should have zero mean, by construction of the solution.

Next, collecting the terms of order  $O(\sqrt{\alpha})$ , using relations [\(3.7\)](#page-6-0), [\(3.8\)](#page-6-0) and simplifying the resulting system by virtue of its averaged members, we obtain the system

<span id="page-6-1"></span>
$$
-c_0\tilde{\eta}^{(1)}_{\xi} + c_0^2 \tilde{s}_{\xi}^{(1)} = -\tilde{\eta}^{(0)}_{\tau}, \quad -c_0 \tilde{s}_{\xi}^{(1)} + \tilde{\eta}^{(1)}_{\xi} = -\frac{1}{c_0} \tilde{\eta}^{(0)}_{\tau},
$$
(3.9)

$$
\tilde{v}_{\xi}^{(1)} = \frac{\gamma}{c_0^2} \tilde{\eta}^{(0)}, \quad \tilde{V}_{\xi}^{(1)} = 0,
$$
\n(3.10)

$$
\hat{s}_t^{(1)} = \gamma B^{(0)} - A_\tau^{(0)}, \quad \hat{v}_t^{(1)} = -\gamma A^{(0)} - B_\tau^{(0)}, \quad \hat{V}_t^{(1)} = -\gamma F^{(0)} - C_\tau^{(0)}.
$$
 (3.11)

Equations [\(3.9\)](#page-6-1) imply

$$
\tilde{\eta}_{\tau}^{(0)} = 0, \quad \tilde{s}^{(1)} = \frac{1}{c_0} \tilde{\eta}^{(1)}, \tag{3.12}
$$

again using that all deviations have zero mean.

To avoid secular growth in  $\hat{s}^{(1)}$  and  $\hat{v}^{(1)}$ , we require that

$$
A_{\tau}^{(0)} = \gamma B^{(0)}, \quad B_{\tau}^{(0)} = -\gamma A^{(0)}, \tag{3.13}
$$

which implies  $A_{\tau\tau}^{(0)} = -\gamma^2 A^{(0)}$ , yielding

$$
A^{(0)} = A(T)\cos\gamma[\tau + \phi(T)], \quad B^{(0)} = -A(T)\sin\gamma[\tau + \phi(T)], \tag{3.14}
$$

where  $A(T)$  and  $B(T)$  are arbitrary functions of T.

To avoid secular growth in  $\hat{V}^{(1)}$  one can consider two options:

(i)  $F^{(0)} = F^{(0)}(\tau, T)$ , then  $C_{\tau}^{(0)} = -\gamma F^{(0)}$ , implying

$$
\hat{V}^{(0)} = C^{(0)} = -\gamma \int_0^{\tau} F^{(0)}(\tilde{\tau}, T) d\tilde{\tau};
$$
\n(3.15)

(ii)  $F^{(0)} = F^{(0)}(t, \tau, T)$  such that  $\hat{V}^{(1)} = -\int_0^t [\gamma F^{(0)}(t, \tau, T) + C_\tau^{(0)}(\tau, T)] d\tilde{t}$  is bounded, e.g.  $F^{(0)} = -C_{\tau}^{(0)} + \sin \omega t$ , where  $\omega = \omega(\tau, T)$ .

In what follows, we consider the first case. Then, summarising, we have

$$
\hat{s}^{(0)} = A(T) \cos \gamma [\tau + \phi(T)], \quad \hat{v}^{(0)} = -A(T) \sin \gamma [\tau + \phi(T)], \quad (3.16)
$$

<span id="page-6-2"></span>
$$
\hat{V}^{(0)} = -\gamma \int_0^{\tau} F^{(0)}(\tilde{\tau}, T) d\tilde{\tau}, \quad \tilde{s}^{(0)} = \frac{1}{c_0} \tilde{\eta}^{(0)}(\xi, T), \quad \tilde{v}^{(0)} = 0, \quad \tilde{V}^{(0)} = 0; \tag{3.17}
$$

$$
\hat{s}^{(1)} = A^{(1)}(\tau, T), \quad \hat{v}^{(1)} = B^{(1)}(\tau, T), \quad \hat{V}^{(1)} = C^{(1)}(\tau, T), \quad \tilde{s}^{(1)} = \frac{1}{c_0} \tilde{\eta}^{(1)}, \tag{3.18}
$$

$$
\tilde{v}^{(1)} = \frac{\gamma}{c_0^2} \left( \int_{-L}^{\xi} \tilde{\eta}^{(0)}(\tilde{\xi}, T) d\tilde{\xi} - \left( \int_{-L}^{\xi} \tilde{\eta}^{(0)}(\tilde{\xi}, T) d\tilde{\xi} \right) \right), \quad \tilde{V}^{(1)} = 0. \tag{3.19}
$$

Here,  $\left\langle \int_{-L}^{\xi} \tilde{\eta}^{(0)}(\tilde{\xi},T) d\tilde{\xi} \right\rangle = \frac{1}{2L} \int_{-L}^{L} \left( \int_{-L}^{\xi} \tilde{\eta}^{(0)}(\tilde{\xi},T) d\tilde{\xi} \right) d\xi$  is the mean value.

Finally, collecting the terms at  $O(\alpha)$ , using [\(3.16\)](#page-6-2)–[\(3.19\)](#page-6-2) and simplifying the resulting

system by virtue of its averaged members, we obtain

<span id="page-7-0"></span>
$$
-c_0 \tilde{\eta}_{\xi}^{(2)} + c_0^2 \tilde{s}_{\xi}^{(2)} = -\frac{\sigma}{c_0} (\hat{\eta}^{(0)} + \tilde{\eta}^{(0)}) \tilde{\eta}_{\xi}^{(0)}
$$

$$
-\sigma \left( A(T) \cos \gamma [\tau + \phi(T)] + \frac{1}{c_0} \tilde{\eta}^{(0)} \right) \tilde{\eta}_{\xi}^{(0)} - F^{(0)} \tilde{\eta}_{\xi}^{(0)} - \tilde{\eta}_{\tau}^{(1)} - \tilde{\eta}_{T}^{(0)}, \qquad (3.20)
$$

$$
-c_0 \tilde{s}_{\xi}^{(2)} + \tilde{\eta}_{\xi}^{(2)} = \frac{\gamma}{c_0^2} \left( \int_{-L}^{\xi} \tilde{\eta}^{(0)}(\tilde{\xi}, T) d\tilde{\xi} - \left( \int_{-L}^{\xi} \tilde{\eta}^{(0)}(\tilde{\xi}, T) d\tilde{\xi} \right) \right) - \frac{\beta c_0^2}{3} \tilde{\eta}_{\xi \xi \xi}^{(0)} - \sigma \left( A(T) \cos \gamma [\tau + \phi(T)] + \frac{1}{c_0} \tilde{\eta}^{(0)} \right) \tilde{\eta}_{\xi}^{(0)} - \frac{1}{c_0} (F^{(0)} \tilde{\eta}_{\xi}^{(0)} - \tilde{\eta}_{\tau}^{(1)} - \tilde{\eta}_{T}^{(0)}), \quad (3.21)
$$

$$
\tilde{v}_{\xi}^{(2)} = \frac{\gamma}{c_0^2} \tilde{\eta}^{(1)} - \frac{1}{c_0} \left( A_T \sin \gamma [\tau + \phi(T)] + \gamma A \phi_T \cos \gamma [\tau + \phi(T)] \right),
$$
(3.22)

$$
\tilde{V}_{\xi}^{(2)} = -A(T)\sin\gamma[\tau + \phi(T)]\tilde{\eta}_{\xi}^{(0)} - \frac{\gamma}{c_0} \int_0^{\tau} F_T^{(0)}(\tilde{\tau}, T)d\tilde{\tau},
$$
\n(3.23)

$$
\hat{s}_{t}^{(2)} = \gamma B^{(1)} - A_{\tau}^{(1)} - A_{T} \cos \gamma [\tau + \phi(T)] + \gamma A \phi_{T} \sin \gamma [\tau + \phi(T)],
$$
\n(3.24)

$$
\hat{v}_t^{(2)} = -\gamma A^{(1)} - B_\tau^{(1)} + A_T \sin \gamma [\tau + \phi(T)] + \gamma A \phi_T \cos \gamma [\tau + \phi(T)],
$$
\n(3.25)

$$
\hat{V}_t^{(2)} = -\gamma F^{(1)} - C_\tau^{(1)} + \gamma \int_0^\tau F_T^{(0)}(\tilde{\tau}, T) d\tilde{\tau}.
$$
\n(3.26)

Equations  $(3.20)$  and  $(3.21)$  yield the equation

<span id="page-7-1"></span>
$$
2\tilde{\eta}_{T}^{(0)} + \left[\frac{\sigma\hat{\eta}^{(0)}}{c_{0}} + 2\sigma A \cos\gamma(\tau + \phi) + 2F^{(0)}(\tau, T)\right]\tilde{\eta}_{\xi}^{(0)} + \frac{3\sigma}{c_{0}}\tilde{\eta}^{(0)}\tilde{\eta}_{\xi}^{(0)} + \frac{\beta c_{0}^{3}}{3}\tilde{\eta}_{\xi\xi\xi}^{(0)} - \frac{\gamma^{2}}{c_{0}}\left(\int_{-L}^{\xi}\tilde{\eta}^{(0)}(\tilde{\xi}, T)d\tilde{\xi} - \sum_{-L}^{\xi}\tilde{\eta}^{(0)}(\tilde{\xi}, T)d\tilde{\xi} > \right) + 2\tilde{\eta}_{\tau}^{(1)} = 0. (3.27)
$$

Differentiating equation (3.[27](#page-7-1)) with respect to  $\tau$ , we obtain

<span id="page-7-3"></span>
$$
\tilde{\eta}_{\tau}^{(1)} = -[\sigma A \cos \gamma (\tau + \phi) - F^{(0)}] \tilde{\eta}_{\xi}^{(0)},
$$
\n(3.28)

which yields, using that the function should have zero mean,

<span id="page-7-2"></span>
$$
\tilde{\eta}^{(1)} = -\left[\frac{\sigma A}{\gamma}\sin\gamma(\tau + \phi) + \int_0^{\tau} F^{(0)}(\tilde{\tau}, T)d\tilde{\tau}\right] \tilde{\eta}_{\xi}^{(0)}.
$$
\n(3.29)

Then, using [\(3.29\)](#page-7-2), equation [\(3.28\)](#page-7-3) yields the Ostrovsky equation in the form

$$
2\tilde{\eta}_{T}^{(0)} + \frac{\sigma \hat{\eta}^{(0)}}{c_0} \tilde{\eta}_{\xi}^{(0)} + \frac{3\sigma}{c_0} \tilde{\eta}^{(0)} \tilde{\eta}_{\xi}^{(0)} + \frac{\beta c_0^3}{3} \tilde{\eta}_{\xi \xi \xi}^{(0)} - \frac{\gamma^2}{c_0} \left( \int_{-L}^{\xi} \tilde{\eta}^{(0)}(\tilde{\xi}, T) d\tilde{\xi} - \left( \int_{-L}^{\xi} \tilde{\eta}^{(0)}(\tilde{\xi}, T) d\tilde{\xi} \right) \right) = 0.
$$
 (3.30)

Differentiating with respect to  $\xi$  and changing the variable  $\xi$  to  $\zeta = \xi - \frac{\sigma \hat{\eta}^{(0)}}{2c_0}$  $\frac{\tau \hat{\eta}^{(0)}}{2c_0}T$  leads to the traditional form

<span id="page-7-4"></span>
$$
\left(\tilde{\eta}_{T}^{(0)} + \alpha_{1}\tilde{\eta}^{(0)}\tilde{\eta}_{\zeta}^{(0)} + \beta_{1}\tilde{\eta}_{\zeta\zeta\zeta}^{(0)}\right)_{\zeta} = \gamma_{1}\tilde{\eta}^{(0)},\tag{3.31}
$$

*Evolution of internal cnoidal waves with local defects in a two-layer fluid with rotation* 9 where

$$
\alpha_1 = \frac{3\sigma}{2c_0}, \quad \beta_1 = \frac{\beta c_0^3}{6}, \quad \gamma_1 = \frac{\gamma^2}{2c_0}.
$$

Next, substituting equation [\(3.29\)](#page-7-2) for  $\tilde{\eta}^{(1)}$  in equation [\(3.22\)](#page-7-0) for  $\tilde{v}^{(2)}_{\xi}$  and requiring that there is no secular growth in  $\tilde{v}^{(2)}$ , and that the function has zero mean, we conclude that

$$
A_T = 0, \quad \phi_T = 0, \quad \tilde{v}^{(2)} = -\left[\frac{\sigma A}{c_0^2} \sin \gamma (\tau + \phi) + \frac{\gamma}{c_0^2} \int_0^{\tau} F^{(0)}(\tilde{\tau}, T) d\tilde{\tau}\right] \tilde{\eta}^{(0)}.
$$
 (3.32)

Similarly, equation [\(3.24\)](#page-7-0) yields

$$
F_T^{(0)} = 0
$$
, and  $\tilde{V}^{(2)} = -A \sin \gamma (\tau + \phi) \tilde{\eta}^{(0)}$ . (3.33)

Finally, the equations for the mean values simplify to take the form

$$
\hat{s}_t^{(2)} = \gamma B^{(1)} - A_\tau^{(1)}, \quad \hat{v}_t^{(2)} = -\gamma A^{(1)} - B_\tau^{(1)}, \quad \hat{V}_t^{(2)} = -\gamma F^{(1)} - C_\tau^{(1)}.
$$
 (3.34)

Assuming that  $F^{(1)} = F^{(1)}(\tau, T)$ , we then have

$$
A_{\tau}^{(1)} = \gamma B^{(1)}, \quad B_{\tau}^{(1)} = -\gamma A^{(1)}, \quad C_{\tau}^{(1)} = -\gamma F^{(1)}, \tag{3.35}
$$

yielding similar conclusions to those for  $(A, B, C)^{(0)}$ . In what follows, we consider  $(F, A, B, C)^{(1)} = 0.$ 

Hence, considering the equations up to  $O(\alpha)$ , i.e. up to the accuracy of the governing equations [\(2.12\)](#page-4-1)–[\(2.19\)](#page-5-2), allows us to fully define all terms at  $O(1)$  and  $O(\sqrt{\alpha})$ . The procedure can be continued to any order, but instead of using the truncated weakly-nonlinear formulation, we would need to use the original strongly-nonlinear equations.

To summarise, up to the accuracy of the governing equations, we obtained the following large class of uni-directional waves described by the Ostrovsky equation and propagating over the non-zero, generally evolving, mean fields:

$$
\eta = \hat{\eta}^{(0)} + \tilde{\eta}^{(0)} - \sqrt{\alpha} \left[ \frac{\sigma A}{\gamma} \sin \gamma (\tau + \phi) + \int_0^{\tau} F^{(0)}(\tilde{\tau}) d\tilde{\tau} \right] \tilde{\eta}_{\zeta}^{(0)} + O(\alpha), \quad (3.36)
$$
  

$$
s = A \cos \gamma (\tau + \phi) + \frac{1}{c_0} \tilde{\eta}^{(0)}
$$

$$
-\sqrt{\alpha} \frac{1}{c_0} \left[ \frac{\sigma A}{\gamma} \sin \gamma (\tau + \phi) + \int_0^{\tau} F^{(0)}(\tilde{\tau}) d\tilde{\tau} \right] \tilde{\eta}_{\zeta}^{(0)} + O(\alpha), \tag{3.37}
$$

$$
v = -A\sin\gamma(\tau + \phi)
$$

$$
+\sqrt{\alpha}\frac{\gamma}{c_0^2}\left[\int_{-L}^{\zeta}\tilde{\eta}^{(0)}(\tilde{\zeta},T)d\tilde{\zeta}-\left\langle \int_{-L}^{\zeta}\tilde{\eta}^{(0)}(\tilde{\zeta},T)d\tilde{\zeta}\right\rangle\right]+O(\alpha),\tag{3.38}
$$

$$
V = -\gamma \int_0^{\tau} F^{(0)}(\tilde{\tau}) d\tilde{\tau} + O(\alpha), \qquad (3.39)
$$

where  $\hat{\eta}^{(0)}$ , A,  $\phi$  are arbitrary constants,  $F^{(0)}(\tilde{\tau})$  is a function such that  $\int_0^{\tau} F^{(0)}(\tilde{\tau}) d\tilde{\tau}$  is bounded (e.g.  $\sin \omega \tilde{\tau}$ ), and  $\tilde{\eta}^{(0)} = \tilde{\eta}^{(0)}(\zeta, T)$  satisfies the Ostrovsky equation [\(3.31\)](#page-7-4), where

$$
\zeta = \xi - \frac{\sigma \hat{\eta}^{(0)}}{2c_0} T = x - \left( c_0 + \frac{\alpha \sigma \hat{\eta}^{(0)}}{2c_0} \right) t, \quad T = \alpha t. \tag{3.40}
$$

We note that the function  $\tilde{n}^{(0)}$  has zero mean by construction, *n* has a constant mean value.

while the shear variables  $s$  and  $v$  generally have time-dependent mean values. The barotropic transport variables  $F$  and  $V$  are also generally time-dependent. In the rest of this paper we consider the case  $F^{(0)} = 0$  (i.e., the barotropic transport is absent).

#### <span id="page-9-0"></span>**4. The effect of rotation on the evolution of cnoidal waves with defects**

The aim of this section is to model the evolution of the waves generated by initial conditions close to the cnoidal waves of the KdV equation but having local amplitude and/or periodicity defects. We use the weakly-nonlinear solution constructed in Section [3](#page-5-0) and first model the effect of rotation on the exact classical solutions of the KdV equation: solitons and cnoidal waves [\(Boussinesq](#page-29-1) [1871;](#page-29-1) [Korteweg and de Vries](#page-30-3) [1895\)](#page-30-3), as well as bright and dark breathers [\(Kuznetsov & Mikhailov](#page-30-6) [1975;](#page-30-6) [Hoefer et al.](#page-30-11) [2023\)](#page-30-11). Then, we consider cnoidal waves with the local contraction and expansion periodicity defects introduced by symmetrically cutting away a part close to the trough between the two neighbouring peaks and gluing together the remaining parts of the solution, and by cutting at the trough and symmetrically inserting a piece of a straight line, respectively (see the first two rows in Figure [17](#page-27-0) of the Appendix A). This allows us to set up a framework for the discussion of the effects observed in our subsequent modelling of cnoidal waves with generic localised defects. As a by-product of our study of initial conditions with local periodicity defects we came across an observation that these functions are in fact weak solutions of the KdV equation. In Appendix [A,](#page-25-0) we prove that all conservation laws of the KdV equation (inifinitely many) are identically satisfied for them. Moreover, the expansion defect has a smooth first derivative.

In our numerical experiments, we use two sets of parameters. In the first set, which is used for the majority of our simulations (except the runs shown in Figures [13,](#page-21-0) [14](#page-22-0) (right) and [15](#page-22-1) (right)), the pycnocline is closer to the surface, and internal waves are the waves of depression. Hence, we show the bottom view in the majority of our figures in this section. The depths of the upper and lower layers are 37.5 m and 112.5 m, respectively, and the total depth of the system, denoted by  $H$ , is 150.0 m. The densities of the upper and lower layers are chosen to be  $\rho_1 = 1000.0$ ,  $\rho_2 = 1003.1$  kg m<sup>-3</sup>, respectively. The small parameters are defined as  $\alpha = a/H$ ,  $\tilde{\beta} = (H/l)^2$  and  $\tilde{\gamma} = (lf)/\sqrt{(g'H)}$ , where a is a wave amplitude, l is a wavelength, f is the Coriolis parameter,  $g' = g\Delta\rho/\rho_1$  is the reduced gravity. We let  $\alpha = 0.005$  and  $\tilde{\beta} = 0.030$ . We assume midlatitude oceanic values for the Coriolis parameter  $f = 5 \times 10^{-5}$  s<sup>-1</sup>, and reduced gravity  $g' = 0.030$  m s<sup>-2</sup>. Hence,  $\tilde{\gamma} \approx 0.020$ . The nondimensional unperturbed upper layer depth  $h_0 = 0.250$  gives values of the linear long wave speed  $c_0 = (h_0 - h_0^2)^{1/2} \approx 0.433$  and coefficient  $\sigma = 2h_0 - 1 = -0.500$ . The scaled  $O(1)$ parameters are  $\beta = \tilde{\beta}/\alpha$  and  $\gamma = \tilde{\gamma}/\sqrt{\alpha}$ . Then, the coefficients of the Ostrovsky equation [\(3.31\)](#page-7-4) are given by  $\alpha_1 \approx -1.732$ ,  $\beta_1 \approx 0.081$ ,  $\gamma_1 \approx 0.096$ . This regime is close to one of the regimes considered by [Helfrich](#page-30-17) [\(2007\)](#page-30-17), and internal waves are waves of depression. The second set of parameters is used to model the internal waves of elevation shown in Figures [13,](#page-21-0) [14](#page-22-0) (right) and [15](#page-22-1) (right), and here the pycnocline is closer to the bottom: the depths of the upper and lower layers are 120.0 and 30.0 m, respectively. The total depth of the system is again  $H = 150.0$  m. The other parameters are unchanged except the non-dimensional unperturbed upper layer depth  $h_0 = 0.800$ , giving values of the linear long wave speed  $c_0 = (h_0 - h_0^2)^{1/2} = 0.400$  and coefficient  $\sigma = 2h_0 - 1 = 0.600$ . Then, the coefficients of the Ostrovsky equation [\(3.31\)](#page-7-4) are found to be  $\alpha_1 = 2.250$ ,  $\beta_1 = 0.064$ ,  $\gamma_1 \approx 0.104$ . The Ostrovsky equation is solved using a pseudospectral method described in Appendix [B.](#page-28-0) Parameters specifying the inertial oscillations ("twitching") are chosen to be  $A = 1$  and  $\phi = 0$ , and  $A = 0$  in the KdV regime (no rotation).

*Evolution of internal cnoidal waves with local defects in a two-layer fluid with rotation*11

#### 4.1. *The effect of rotation on solitons and cnoidal waves*

We begin by modelling the evolution of initial conditions in the form of solitary and cnoidal wave solutions of the KdV equation associated with the Ostrovsky equation [\(3.31\)](#page-7-4):

<span id="page-10-0"></span>
$$
\tilde{\eta}_T^{(0)} + \alpha_1 \tilde{\eta}^{(0)} \tilde{\eta}_\zeta^{(0)} + \beta_1 \tilde{\eta}_{\zeta \zeta \zeta}^{(0)} = 0.
$$
\n(4.1)

Hence, at  $T = 0$  the initial condition for the Ostrovsky equation [\(3.31\)](#page-7-4) corresponding to the soliton solution is given by the mean-free part of the function

$$
\tilde{\eta}^{(0)} = \frac{3v_s}{\alpha_1} \text{sech}^2 \left[ \frac{1}{2} \sqrt{\frac{v}{\beta_1}} (\zeta - v_s T - \zeta_0) \right]_{T=0},\tag{4.2}
$$

where  $\zeta_0$  and  $v_s > 0$  are arbitrary constants, while the initial condition for the Ostrovsky equation  $(3.31)$  corresponding to the cnoidal wave of equation  $(4.1)$  takes the form of the mean-free part of the solution given in terms of the Jacobi elliptic functions by

$$
\tilde{\eta}^{(0)} = \frac{6\beta_1}{\alpha_1} \left\{ u_2 + (u_3 - u_2) \text{ cn}^2 \left[ (\zeta - v_c) \sqrt{\frac{u_3 - u_1}{2}}; m \right] \right\}_{T=0},\tag{4.3}
$$

where  $u_1 < u_2 < u_3$  are real,  $v_c = 2\beta_1(u_1 + u_2 + u_3)$ , and  $m = (u_3 - u_2)/(u_3 - u_1)$  is the elliptic modulus. In the limit  $m \to 1$ , the cnoidal wave approaches a soliton (generally, on a non-zero pedestal). The period of the cnoidal wave is given by

$$
\lambda = \frac{2K(m)}{\sqrt{(u_3 - u_1)/2}},\tag{4.4}
$$

where  $K(m)$  is the complete elliptic integral of the first kind (see, for example, [Kamchatnov](#page-30-21) [2000\)](#page-30-21).

In Figure [3,](#page-11-0) we compare the evolution of a single soliton in a two-layer fluid system with rotation in numerical experiments with periodic boundary conditions, either with or without the sponge layers near the boundaries (see, for example, [Alias et al.](#page-29-2) [2013](#page-29-2) for the discussion of the sponge layers). The sponge layers near the boundaries act as a filter absorbing the radiation. The computational domain is  $2L = 100$ , with the number of modes  $M = 998$ , the spatial step  $\Delta x \approx 10^{-1}$ , the total simulation time  $T_{max} = 200$ , and the temporal step  $\Delta T = 10^{-2}$ . Other constants are  $v_s \approx 0.487$  and  $\zeta_0 = 0$ .

Top row of Figure [3](#page-11-0) shows three-dimensional plots of the time evolution of the interfacial displacement for initial conditions in the form of a single soliton, without (left) and with (right) the sponge layers near the boundaries of the periodic domain. The soliton evolves into a wavepacket as it propagates, and for a long time the radiation penetrating through the boundaries in the absence of sponge layers does not have a large effect on the shape or speed of the main wavepacket, which is shown in more detail in the middle and bottom rows of Figure [3.](#page-11-0) The overall wave pattern remains stable and consistent throughout the simulation.

Similarly, in Figure [4](#page-12-0) we show the effect of rotation on the cnoidal wave initial condition. The computational domain is  $2L = 26.40$ , with the number of modes  $M = 262$ , the spatial step  $\Delta x \approx 10^{-1}$ , the total simulation time  $T_{max} = 100$ , and the temporal step  $\Delta T = 10^{-2}$ . The parameters characterising the initial condition are  $u_1 = -10^{-3}$ ,  $u_2 = 0$  and  $u_3 = 3$ . It is evident that rotation leads to formation of a rather regular quasi-periodic wave pattern shown in Figure [4,](#page-12-0) without the formation of bursts of large waves.

We also note that both for the soliton and cnoidal wave initial conditions the time evolution of the maximum and minimum of the free-surface elevation is quasi-periodic, with no significant bursts, as shown in Figure [5.](#page-12-1) All computational parameters are the same as in the

<span id="page-11-0"></span>

Figure 3: The effect of rotation on the KdV soliton initial condition in simulations with periodic boundary conditions. First row: view from above (left) and view from below (right) of the interfacial displacement. Second row: interfacial displacement in simulations without the sponge layers (left) and with the sponge layers (right). Third row: comparison of the lead wavepacket in simulations without the sponge layers (black) and with the sponge layers (red dashed).

*Evolution of internal cnoidal waves with local defects in a two-layer fluid with rotation*13

<span id="page-12-0"></span>

Figure 4: The effect of rotation on the KdV cnoidal wave initial condition: view from above (left) and view from below (right) of the interfacial displacement.

<span id="page-12-1"></span>

Figure 5: Evolution of the maximum, minimum and amplitude of the interfacial displacement for a soliton (left) and cnoidal wave (right) initial condition on a periodic domain under the effect of rotation.

previous figures. Hence, we conclude that rotation alone does not trigger formation of large waves in these simulations.

#### 4.2. *The effect of rotation on breathers on a cnoidal wave background*

The exact breather on a cnoidal wave solutions of the KdV equation were studied by [Kuznetsov & Mikhailov](#page-30-6) [\(1975\)](#page-30-6); [Hoefer et al.](#page-30-11) [\(2023\)](#page-30-11). There are two types of breathers: bright and dark (this terminology refers to the canonical form of the KdV equation, where solitons are waves of elevation). For a bright breather propagating as a dislocation of a cnoidal wave the exact solution of the KdV equation  $(4.1)$  takes the form

<span id="page-12-2"></span>
$$
\tilde{\eta}^{(0)} = \frac{12\beta_1}{\alpha_1} \Big\{ k^2 - 1 + \frac{E(k)}{K(k)} + \frac{\partial^2}{\partial \zeta^2} \Big[ \log \big( \tau(\zeta, \beta_1 T) \big) \Big] \Big\},\tag{4.5}
$$

where  $k \in (0, 1)$  is the elliptic modulus (the elliptic parameter  $m = k^2$ ),  $K(k)$  is the complete elliptic integral of the first kind,  $E(k)$  is the complete elliptic integral of the second kind, and the  $\tau$ -function is given by

$$
\tau(x,t) := \Theta(x - c_0 t + \alpha_b) \exp\{\kappa_b (x - c_b t + x_0)\} + \Theta(x - c_0 t - \alpha_b) \exp\{-\kappa_b (x - c_b t + x_0)\}
$$

with  $\kappa_b > 0$ ,  $c_b > c_0$  and  $\alpha_b \in (0, K(k))$ . Here,  $\Theta(x) = \theta_4\left(\frac{\pi x}{2K(k)}\right)$ , where  $\theta_4$  is the Jacobi theta function of type four, given by  $\theta_4(u) = 1 + 2 \sum_{n=1}^{\infty}$  $\overline{n=1}$  $(-1)^n q^{n^2} \cos(2nu)$ . The solution is parameterised by  $\lambda \in (-\infty, -k^2)$ . The parameters are defined as follows [\(Hoefer et al.](#page-30-11) [2023\)](#page-30-11): √

$$
\varphi_{\gamma} = \arcsin\left(\frac{\sqrt{-\lambda - k^2}}{\sqrt{1 - 2k^2 - \lambda}}\right),\tag{4.6}
$$

$$
\alpha_b = F(\varphi_\gamma, k), \quad \kappa_b = \frac{\sqrt{1 - \lambda - k^2} \sqrt{-\lambda - k^2}}{\sqrt{1 - 2k^2 - \lambda}} - Z(\varphi_\gamma, k), \tag{4.7}
$$

$$
c_0 = 4(2k^2 - 1), \quad c_b = c_0 + \frac{4\sqrt{1 - \lambda - 2k^2}\sqrt{1 - \lambda - k^2}\sqrt{-\lambda - k^2}}{k_b},\tag{4.8}
$$

where  $F(\varphi, k) := \int_0^{\varphi} \frac{d\theta}{\sqrt{1-\theta^2}}$  $\frac{d\theta}{1-k^2\sin^2\theta}$  is the elliptic integral of the first kind, and  $Z(\varphi, k) :=$ 

 $\int_0^{\varphi} \sqrt{1 - k^2 \sin^2 \theta} d\theta$  is the elliptic integral of the second kind.

For a dark breather propagating as a dislocation of a cnoidal wave the exact solution is again given by equation [\(4.5\)](#page-12-2), where the solution is now parameterised by  $\lambda \in (1 - 2k^2, 1 - k^2)$ , and the  $\tau$ -function takes the form

$$
\tau(x,t) := \Theta(x - c_0 t + \alpha_d) \exp\{-\kappa_d (x - c_d t + x_0)\} + \Theta(x - c_0 t - \alpha_d) \exp\{\kappa_d (x - c_d t + x_0)\}
$$

with  $\kappa_d > 0$ ,  $c_d < c_0$  and  $\alpha_d \in (0, K(k))$ . The parameters are given by

$$
\varphi_{\alpha} = \arcsin\left(\frac{\sqrt{1 - k^2 - \lambda}}{k}\right),\tag{4.9}
$$

$$
\alpha_d = F(\varphi_\alpha, k), \quad \kappa_d = Z(\varphi_\alpha, k), \tag{4.10}
$$

$$
c_0 = 4(2k^2 - 1), \quad c_d = c_0 - \frac{4\sqrt{(k^2 + \lambda)(\lambda - 1 + 2k^2)(1 - k^2 - \lambda)}}{\kappa_d}.
$$
 (4.11)

Numerical solutions initiated with the bright and dark breather on a cnoidal wave initial conditions in the absence of rotation are shown in the first row of Figure [6.](#page-14-0) For the bright breather simulations, shown in the left column, the computational domain length is  $2L =$ 72.86, with the number of modes  $M = 728$ , the spatial step  $\Delta x \approx 10^{-1}$ , the total simulation time  $T_{max} = 100$ , and the temporal step  $\Delta T = 10^{-2}$ . The parameters used in the initial condition are  $[k, \lambda] \approx [0.9998, -1.30]$ . For the dark breather simulations, shown in the right column, the computational domain length is  $2L = 80.64$ , with the number of modes  $\overline{M} = 804$ , the spatial step  $\Delta x \approx 10^{-1}$ , the total simulation time  $T_{max} = 100$ , and the temporal step  $\Delta T = 10^{-2}$ . The other parameters are  $[k, \lambda] \approx [0.9998, -0.50]$ . In the absence of rotation, the plots show stable propagation of the bright and dark breather solutions on top of the cnoidal wave, in full agreement with the available analytical solution  $(4.5)$ .

Next, the effect of rotation on the evolution of the bright breather on a cnoidal wave initial condition is shown in the subsequent rows of the same Figure [6,](#page-14-0) for the interfacial displacement (second row), shear in the direction of wave propagation (third row) and shear in the orthogonal direction (fourth row). We notice a striking difference with the results shown in the top row of the figure (no rotation): there emerges a rather strong left-propagating localised burst clearly visible both in the free surface elevation (second row) and the shear in the direction of wave propagation (third row). The counterpart of the wave is also present in the shear in the orthogonal direction (fourth row), but this signal is weak. It must be noted that the wave forms soon after the initiation of the simulation, and it continues to grow for a long time.

<span id="page-14-0"></span>

*Evolution of internal cnoidal waves with local defects in a two-layer fluid with rotation*15

Figure 6: Numerical solution for a bright (left) and dark (right) breather on a cnoidal wave initial condition (view from below). First row: interfacial displacement in the absence of rotation. Second row: interfacial displacement under the effect of rotation. Third / fourth row: shear in the direction of wave propagation / orthogonal direction, under the effect of rotation.

<span id="page-15-0"></span>

Figure 7: The effect of rotation on the evolution of the maximum, minimum and amplitude of the interfacial displacement for a bright (left) and dark (right) breather on a cnoidal wave initial condition. Black solid, red dashed and blue dot-dashed lines correspond to 5, 7 and 9 peaks in the domain, respectively.

<span id="page-15-1"></span>

Figure 8: Close-up view from below of the large burst in the interfacial displacement for a bright (left) and dark (right) breather on a cnoidal wave initial condition around  $T = 40$ (left) and  $T = 10$  (right), respectively.

In these runs, the effect on a dark breather on a cnoidal wave is qualitatively similar to that on the bright breather, though less pronounced. In both cases, the background cnoidal wave continues propagating to the right (in the moving reference frame), and there appears a significant burst both in the interfacial displacement and the shear in the direction of wave propagation, moving to the left. For the dark breather, the signal in the shear in the orthogonal direction is also present, but it is barely noticeable to the naked eye.

Figure [7](#page-15-0) shows the time evolution of the maximum, minimum and the amplitude of the interfacial displacement for both cases of a bright (left column) and dark (right column) breather on a cnoidal wave initial condition. We see that the observed effects of rotation are structurally stable with regard to the size of the computational domain. We experimented with 5, 7 and 9 major peaks in the domain. In the bright-breather case, the computational domains are  $2L = 37.42$  (5 peaks),  $2L = 55.02$  (7 peaks),  $2L = 72.86$  (9 peaks). For the dark-breather case, the computational domains are  $2L = 45.44$  (5 peaks),  $2L = 63.04$  (7 peaks),  $2L = 80.64$  (9 peaks). The remaining numerical parameters are the same as before. It is again evident that the wave amplitude grows. The burst forms soon after the initiation of the numerical runs. The close-up views of the large waves visible in the free surface elevation are

#### *Evolution of internal cnoidal waves with local defects in a two-layer fluid with rotation*17

shown in Figure [8](#page-15-1) for the time around  $T = 40$  (bright breather case, left) with approximately 32% increase in the amplitude compared to the initial condition, and around  $T = 10$  (dark breather case, right) with approximately 18% increase in the amplitude compared to the initial condition. Hence, we conclude that under the effect of rotation the moving dislocation on top of the otherwise regular cnoidal wave can lead to the emergence of strong bursts of interfacial waves and shear currents in the direction of propagation of the cnoidal wave.

#### 4.3. *The effect of rotation on cnoidal waves with periodicity defects*

Recent research related to the wave packets described by the Schrödinger equation has shown that localised phase defects can lead to the emergence of rogue waves [\(He et al.](#page-30-9) [2022\)](#page-30-9). Here, we investigate whether periodicity defects introduced into the long cnoidal waves in the KdV-Ostrtovsky regime can also lead to the emergence of large localised bursts of energy, under the effect of rotation. Also, can it happen already in the absence of rotation, i.e. in the KdV regime?

Motivated by Figure [1,](#page-2-0) we consider cnoidal waves close to their solitonic limit and introduce two types of periodicity defects (see Figure [17](#page-27-0) in Appendix A): contraction and expansion defects, depending on whether the distance between the two neighbouring peaks is shorter or longer than the period of the cnoidal wave. The first defect is introduced by symmetrically cutting away a small part close to the trough between the two neighbouring peaks, and gluing together the remaining parts of the solution. Naturally, the resulting function has discontinuous derivative at one point within the computational domain, but the jump in the derivative is small because we have cut close to extremum (smoothed in numerical simulations). The second defect is introduced by cutting the graph at the trough and symmetrically inserting a piece of a straight line. The resulting function has continuous first derivative. To our surprise, these functions evolved almost like travelling waves of the KdV equation. Both types of waves were long-lived, and cnoidal wave with an expansion defect was stable, with no visible changes at the end of the long run. The numerical results initiated with such initial conditions in the absence of rotation are shown in the first row of Figure [9](#page-17-0) for the contraction defect (left column) and the expansion defect (right column). Intrigued by this observation, we managed to prove that for the constructed functions (and their natural generalisations) all (infinitely many) conservation laws of the KdV equation are satisfied exactly. This approach was inspired by the recent work by [Gavrilyuk et al.](#page-30-22) [\(2020\)](#page-30-22); [Gavrilyuk and Shyue](#page-30-23) [\(2022\)](#page-30-23); [Gavrilyuk et al.](#page-30-24) [\(2024\)](#page-30-24), where some solutions with singularities satisfying the Weierstrass–Erdmann corner conditions (e.g. [Fox](#page-30-19) [1954\)](#page-30-19) and requiring the continuity of the derivative at the junction, were constructed in the context of non-integrable Benjamin–Bona–Mahoney and conduit equations. To the best of our knowledge, the discontinuous travelling wave solutions of the KdV equation in the form of cnoidal waves with periodicity defects constructed in our paper have not been discussed before. A cnoidal wave with an expansion defect satisfies the corner condition exactly and is a weak solution of the KdV equation, it's smoothed counterpart was extremely stable in our numerical runs, but a smoothed counterpart of a cnoidal wave with a contraction defect also turned out to be long-lived, and could be viewed as an approximate weak solution. The proof and further discussion of solutions of the KdV equation with defects (both stable and unstable) can be found in Appendix [A.](#page-25-0) Importantly, we conclude that, for the duration of our long simulations, such natural periodicity defects do not lead to the focusing of energy in the absence of rotation.

Next, we use the mean-free part of these (approximate and exact) weak solutions of the KdV equation as the initial conditions for the Ostrovsky equation  $(3.31)$ . The effect of rotation on the cnoidal wave with a contraction and expansion defects is shown in the subsequent rows of the same Figure [9,](#page-17-0) in the left and right columns, respectively, for the interfacial

<span id="page-17-0"></span>

Figure 9: Numerical solution for a cnoidal wave with a contraction (left) and expansion (right) defect initial condition (view from below). First row: interfacial displacement in the absence of rotation. Second row: interfacial displacement under the effect of rotation. *Evolution of internal cnoidal waves with local defects in a two-layer fluid with rotation*19

<span id="page-18-0"></span>

Figure 10: The effect of rotation on the evolution of the maximum, minimum and amplitude of the interfacial displacement for a cnoidal wave with a contraction (left) and expansion (right) defect initial condition. Black solid, red dashed and blue dot-dashed lines correspond to 5, 7 and 9 peaks in the domain, respectively.

<span id="page-18-1"></span>

Figure 11: Close-up view from below of the large burst in the interfacial displacement for a cnoidal wave with a contraction (left) and expansion (right) defect around  $T = 27$  (left) and  $T = 35$  (right), respectively.

displacement (first row), shear in the direction of wave ropagation (third row) and shear in the orthogonal direction (fourth row). Here, we see the formation of a strong burst of the interfacial waves and shear in the direction of wave propagation. In the moving reference frame the burst propagates to the left. Qualitatively, this is similar to the behaviour observed in the previous section, where numerical runs were initiated using the breather on a cnoidal wave initial conditions, but the important difference is that this effect is solely due to rotation and no bursts of any kind are present in the absence of rotation.

Figure [10](#page-18-0) shows the time evolution of the maximum, minimum and amplitude of the interfacial displacement for both cases of a contraction (left) and expansion (right) periodicity defects. We show that the observed effects of rotation are structurally stable with regard to the size of the computational domain. We experimented with 5, 7 and 9 major peaks in the domain. In the contraction defect case, the computational domains are  $2L = 37.42$  (5 peaks),  $2L = 55.02$  (7 peaks),  $2L = 72.86$  (9 peaks). In the expansion defect case, the computational domains are  $2L = 45.44$  (5 peaks),  $2L = 63.04$  (7 peaks),  $2L = 80.64$  (9 peaks). The remaining numerical parameters are the same as before. The burst forms soon after the initiation of the numerical runs, and the wave continues to grow for a long time after that.

The close-up view of the large wave visible in the free surface elevation is shown in Figure [11](#page-18-1) for the time around  $T = 25$  (contraction defect, left), with approximately 53% increase in the amplitude compared to the initial condition and around  $T = 35$  (expansion defect, right), with an approximately 34% increase in the amplitude compared to the initial condition. Hence, we conclude that under the effect of rotation both contraction and expansion defects present in the otherwise regular cnoidal wave can lead to the emergence of strong bursts of interfacial waves and shear currents in the direction of propagation of the cnoidal wave.

#### <span id="page-19-0"></span>4.4. *The effect of rotation on cnoidal waves with generic localised defects*

Finally in this section, motivated by the recent numerical and experimental generation of breathers in a fluid conduit during the interaction of a cnoidal wave with a soliton by [Maiden](#page-30-8) [and Hoefer](#page-30-8) [\(2016\)](#page-30-8); [Mao et al.](#page-30-12) [\(2023\)](#page-30-12) and generalising this scenario, we initiate numerical runs for our problem with the initial condition which can be described as a cnoidal wave with a generic localised perturbation. Namely, the initial condition is given by the mass-free part of the function

$$
\tilde{\eta}^{(0)} = \frac{6\beta_1}{\alpha_1} \left\{ u_2 + (u_3 - u_2) \operatorname{cn}^2 \left[ (\zeta - v_c) \sqrt{\frac{u_3 - u_1}{2}}; m \right] \right\}_{T=0} + A_1 \operatorname{sech}^2 \left[ A_2(\zeta + \zeta_0) \right],\tag{4.12}
$$

and  $u_1 < u_2 < u_3$  are real,  $v_c = 2\beta_1(u_1 + u_2 + u_3)$ ,  $m = (u_3 - u_2)/(u_3 - u_1)$ , where  $A_1, A_2$ and  $\zeta_0$  are arbitrary constants.

We experiment with both sets of physical parameters discussed at the beginning of Section [4.](#page-9-0) For the first set, numerical solutions initiated with the initial condition with a generic localised defect are shown in Figure [12.](#page-20-0) The computational domain is  $2L = 79.20$ , with the number of modes  $M = 790$ , the spatial step  $\Delta x \approx 10^{-1}$ , the total simulation time  $T_{max} = 100$ , and the temporal step  $\Delta T = 10^{-2}$ . The parameters used in the initial condition are  $u_1 = -10^{-3}$ ,  $u_2 = 0$ ,  $u_3 = 3$ ,  $A_1 = -0.80$ ,  $A_2 = 1.00$ , and  $\zeta_0 = -1.30$ .

The initial condition introduces a localised perturbation to the otherwise regular cnoidal wave. In our runs, in the absence of rotation, the introduction of such a localised defect leads to the formation of a pair of bright and dark breathers, as well as the clearly noticeable expansion defect, which is shown in the first row of the Figure [12,](#page-20-0) showing both the view from above (left) and the view from below (right). Qualitatively, this is similar to the waves generated in the interaction of a cnoidal wave with a solitary wave in a conduit in [Mao et al.](#page-30-12) [\(2023\)](#page-30-12). In the moving reference frame, the bright breather propagates to the right, while the dark breather propagates to the left, and the expansion defect moves with the speed of the cnoidal wave. The effect of rotation on the evolution of the same initial condition is shown in the subsequent rows of the same figure, for the top (left) and bottom (right) views of the interfacial displacement (second row), shear in the direction of wave propagation (third row) and shear in the orthogonal direction (fourth row). There are strong bursts both in the interfacial displacement and shear in the direction of wave propagation, which can be associated with the previously considered types of "defects" in the otherwise regular cnoidal wave. The signal in the shear in the orthogonal direction is again weak. Hence, we conclude that the mechanism of formation of the bursts of strong interfacial displacements and shear in the direction of wave propagation in these simulations can be interpreted as formation of KdV-type breathers and the expansion defect on a cnoidal wave background, with the subsequent effect of rotation.

In order to test our theoretical framework further, we also modelled the effect of rotation on internal waves of elevation, using our second set of parameters discussed at the beginning of Section [4.](#page-9-0) In Figure [13,](#page-21-0) the computational domain is  $2L = 79.20$ , with the number

*Evolution of internal cnoidal waves with local defects in a two-layer fluid with rotation*23

<span id="page-22-0"></span>

Figure 14: The effect of rotation on the evolution of the maximum, minimum and amplitude of the interfacial displacement for a cnoidal wave with a generic localised defect initial condition: waves of depression (left) and waves of elevation (right). Black solid, red dashed and blue dot-dashed lines correspond to 5, 7 and 9 peaks in the domain, respectively.

<span id="page-22-1"></span>

Figure 15: Close-up view from below (left) and above (right) of the large bursts in the interfacial displacement for a cnoidal wave with a generic localised defect initial condition around  $\overline{T}$  = 19 for the waves of depression (left) and waves of elevation (right).

of modes  $M = 790$ , the spatial step  $\Delta x \approx 10^{-1}$ , the total simulation time  $T_{max} = 100$ , and the temporal step  $\Delta T = 10^{-2}$ . The parameters used in the initial condition are  $u_1 =$  $-10^{-3}$ ,  $u_2 = 0$ ,  $u_3 = 3$ ,  $A_1 = 0.80$ ,  $A_2 = 1.00$ , and  $\zeta_0 = -1.30$ . Here, the pycnocline is closer to the bottom, the upper layer depth takes 80% of the total depth, whereas in previous cases it was 25%. The results are similar to our previous simulations for internal waves of depression, but here we see the formation of a pair of bright and dark breathers, as before, but also the noticeable formation of both expansion and contraction defects. The comparison of the evolution of maxima, minima and amplitude of the waves shown in Figures [12](#page-20-0) and [13](#page-21-0) is given in Figure [14,](#page-22-0) illustrating the growth of the amplitude of the waves and further supporting our interpretation of the observed (in all cases) formation of bursts of strong interfacial displacements and shear in the direction of wave propagation. For both sets, the computational domains are  $2L = 44.00$  (5 peaks),  $2L = 61.60$  (7 peaks), and  $2L = 79.20$ (9 peaks). The remaining numerical parameters are the same as before. The results are structurally stable. The large waves formed at the early stage of our computations are shown in Figure [15.](#page-22-1) At around  $T = 19$ , the first and second sets have approximately 37% and 44% increase, respectively, in the amplitudes relative to the initial conditions.

# <span id="page-23-0"></span>**5. Discussion**

In this paper, we addressed several issues related to the modelling of internal waves in the Ostrovsky regime, i.e. in the KdV regime with the account of rotation. We chose Helfrich's f-plane extension (MCC-f) of the two-layer MCC model as our parent system (it would be better to call the system MMCC model, recognising the contribution of [Maltseva](#page-30-18) [1989\)](#page-30-18). The MCC-f model has similar properties to the full Euler equations with rotation with respect to construction of the weakly-nonlinear solution, but the technical details related to the derivation are more manageable. In our derivation, we represented all field variables as the sums of time-dependent mean values and both spatially- and time-dependent deviations from these evolving means. We considered periodic solutions, and mean-field equations were obtained by averaging the equations over the period of the problem. In cotrast to our previous research within the scope of the Boussinesq-type equations, the resulting equations for the mean fields turned out to be coupled to the equations for the deviations, which presented a significant new challenge. We managed to construct a large class of solutions for unidirectional waves by introducing two slow-time variables, and simultaneously constructing asymptotic expansions in powers of the square root of the amplitude parameter (as opposed to the traditional derivation of the Ostrovsky equation with just one slow time and in powers of the amplitude parameter). Since the resulting reduced model, the Ostrovsky equation, has been derived for the zero-mean deviations by construction, the so-called "zero-mean contradiction" meaning the existence of the zero-mean constraints on all field variables of the parent system has been by-passed.

Next, we used the constructed weakly-nonlinear solution combined with extensive numerical modelling using the Ostrovsky equation in order to study the effect of rotation on the evolution of internal waves with initial conditions in the form of the KdV cnoidal waves, but with various local defects. We built the phenomenological framework by considering pure bright and dark breather on a cnoidal wave initial conditions and cnoidal waves with contraction and expansion periodicity defects. The latter defects were introduced 'by hand', by modifying the cnoidal wave solution near the trough in between the two peaks, and we showed that such functions satisfy all (infintely many) conservation laws of the KdV equation. Moreover, the cnoidal waves with an expansion defect also have continuous first derivative, satisfying the so-called 'corner condition' necessary for it to be a non-smooth extremal of the relevant variational problem (see Appendix A). It must be noted that in our numerical runs both the contraction and expansion defects were long-lived, and a cnoidal wave with an expansion defect behaved very close to an exact travelling wave of the KdV equation. The important difference between the defects represented by dislocation- (bright and dark breather) and periodicity- (contraction and expansion) perturbations of the cnoidal wave is that the second type does not lead to formation of bursts in the absence of rotation. Qualitatively, both types of defects lead to formation of bursts of large interfacial displacements and shear in the direction of wave propagation, under the effect of rotation.

Finally, we considered initial conditions in the form of cnoidal waves with generic localised defects. Our modelling has shown that, in the absence of rotation, such initial conditions typically produce a pair of a fast-moving bright and slow-moving dark breathers and expansion and contraction periodicity defects, moving with the speed of the cnoidal wave. Under the effect of rotation, the splitting of a generic localised defect into these 'basic' defects is followed by formation of several bursts of interfacial displacements and shear in the direction of wave propagation, which can be associated with the effect of rotation *Evolution of internal cnoidal waves with local defects in a two-layer fluid with rotation*25

<span id="page-24-0"></span>

Figure 16: Rogue wave generation: 3D and 2D views of the interfacial displacement from above (top row) and initial condition at  $T = 0$  vs interfacial displacement at  $T = 8.8$ (bottom row).

on breathers and the periodicity defects. In all simulations the large bursts propagated to the left in our moving reference frame, i.e. slower than the linear long-wave speed. In this study we did not aim to systematically investigate the probability of generation of rogue waves due to this scenario (in the sense of the classical definition of rogue waves as the waves with the amplitude being more than twice the significant wave height), but it is worth mentioning that it did not take much effort to generate the rogue wave shown in Figure [16](#page-24-0) using the same physical parameters as in Figure [\(13\)](#page-21-0) and initial condition [\(4.12\)](#page-19-0) with  $u_1 = -10^{-3}$ ,  $u_2 = 0$ ,  $u_3 = 3$ ,  $A_1 = 0.60$ ,  $A_2 = 0.60$ , and  $\zeta_0 = -2.60$ . The computational domain is 2L = 272.81 with the number of modes  $M = 2726$ , the spatial step  $\Delta x \approx 10^{-1}$ , the total simulation time  $T_{max} = 100$ , with the temporal step  $\Delta T = 10^{-2}$ . This could be an interesting direction of further research.

We hope that our study sheds light both on the typical structure of nearly cnoidal waves (with defects) observed in oceanic observations (see, for example, Figure 1 in the Introduction), and on the role of rotation in the formation of bursts of large interfacial displacements and shear in the direction of wave propagation. Further developments could concern bi-directional propagation and effects related to barotropic transport, which were discussed in the construction of the weakly-nonlinear solution, but were left out of scope of the subsequent modelling. Another issue which was left out of scope of the present study was the effect of the depth-dependent shear currents (see [Hooper et al.](#page-30-25) [\(2021\)](#page-30-25); [Tseluiko et](#page-31-12) [al.](#page-31-12) [\(2023\)](#page-31-12) for the recent developments related to the presence of a long-wave instability, in the absence of rotation). As a by-product of our study we constructed some curious weak solutions of the KdV equation, whose smoothed counterparts naturally emerged in the evolution of initial conditions in the form of cnoidal waves with local defects. It would be interesting to investigate whether similar solutions can be found in other integrable models, and what is their meaning and role in the relevant physical contexts.

# <span id="page-25-0"></span>**Appendix A.**

The KdV equation

$$
u_t - 6uu_x + u_{xxx} = 0
$$

can be represented in the form of a conservation law

<span id="page-25-1"></span>
$$
\frac{\partial u}{\partial t} + \frac{\partial}{\partial x} \left( -3u^2 + u_{xx} \right) = 0.
$$
 (A1)

Equation  $(A 1)$  implies conservation of 'mass',

$$
\frac{d}{dt} \int_{-L}^{L} u \, dx = 0,\tag{A.2}
$$

provided the function  $u(x, t)$  either vanishes together with its spatial derivatives as  $L \to \infty$ , or it is spatially periodic on the interval  $[-L, L]$ . The latter case is considered in our paper.

Using simple algebra, one can also obtain conservation laws for 'momentum'

$$
\frac{\partial}{\partial t} \frac{u^2}{2} + \frac{\partial}{\partial x} \left( u u_{xx} - \frac{1}{2} u_x^2 - 2 u^3 \right) = 0
$$
 (A 3)

and 'energy'

$$
\frac{\partial}{\partial t}\left(u^3 + \frac{1}{2}u_x^2\right) + \frac{\partial}{\partial x}\left(-\frac{9}{2}u^4 + 3u^2u_{xx} - 6uu_x^2 + u_xu_{xxx} - \frac{1}{2}u_{xx}^2\right) = 0. \tag{A4}
$$

It is well known that the KdV equation has infinitely many polynomial conservation laws, which can be proven using a generating function [\(Miura et al.](#page-31-13) [1968\)](#page-31-13). Indeed, the Gardner transformation

<span id="page-25-2"></span>
$$
u = w + \epsilon w_x + \epsilon^2 w^2, \tag{A5}
$$

where  $\epsilon$  is the grading parameter, yields

$$
u_t - 6uu_x + u_{xxx} = (1 + 2\epsilon^2 w + \epsilon \partial_x)[w_t + (w_{xx} - 3w^2 - 2\epsilon^2 w^3)_x] = 0.
$$
 (A 6)

Therefore, if  $w(x, t)$  satisfies the conservation law

<span id="page-25-4"></span>
$$
w_t + (w_{xx} - 3w^2 - 2\epsilon^2 w^3)_x = 0,
$$
 (A 7)

then  $u(x, t)$  satisfies the KdV equation. Next, one represents w in the form of an asymptotic expansion in powers of  $\epsilon$ :

<span id="page-25-3"></span>
$$
w = \sum_{n=0}^{\infty} \epsilon^n w_n.
$$
 (A 8)

Collecting the coefficients of equal powers of  $\epsilon$  in [\(A 5\)](#page-25-2) gives us

<span id="page-26-0"></span>
$$
w_0 = u
$$
,  $w_1 = -w_{0x} = -u_x$ ,  $w_2 = -w_{1x} - w_0^2 = u_{xx} - u^2$ , (A 9)

$$
w_n = -w_{n-1,x} - \sum_{k=0}^{n-2} w_k w_{n-2-k} \quad \text{for} \quad n \ge 2.
$$
 (A 10)

Now, substituting expansion  $(A 8)$  into  $(A 7)$  one obtains an infinite series of the KdV conservation laws as the coefficients at even powers of  $\epsilon$ . The coefficients of odd powers are exact differentials (referred to as 'trivial conservation laws', see [Miura et al.](#page-31-13) [1968,](#page-31-13) for the details).

The integrals

$$
I_n = \int_{-L}^{L} w_{2n} dx, \quad n = 0, 1, 2, \dots
$$

are called 'Kruskal integrals'. In particular, the first three integrals take the form

$$
I_1 = \int_{-L}^{L} u dx, \quad I_2 = \int_{-L}^{L} \frac{1}{2} u^2 dx, \quad I_3 = \int_{-L}^{L} \left( u^3 + \frac{1}{2} u_x^2 \right) dx.
$$

Next, to prove that cnoidal waves with our contraction and expansion defects satisfy all conservation laws of the KdV equation, we also need a recurrence formula for the fluxes. Substituting expansion  $(A 8)$  into  $(A 7)$  we obtain

$$
w_{xx} - 3w^2 + 2\epsilon^2 w^3 = \sum_{n=0}^{\infty} \epsilon^n f_n,
$$
 (A 11)

where

<span id="page-26-1"></span>
$$
f_0 = w_{0,xx} - 2w_0^2, \quad f_1 = w_{1,xx} - 6w_0w_1, \quad f_2 = w_{2,xx} - 3w_1^2 - 6w_1w_2 + 2w_0^3, \text{(A 12)}
$$

$$
f_n = w_{n,xx} - 3 \sum_{k=0}^{n} w_k w_{n-k} + 2 \sum_{k+l+m=n-2} w_k w_l w_m \quad \text{for} \quad n \ge 2,
$$
 (A 13)

with the last summation being over all triples of integers  $(k, l, m)$  such that  $k + l + m = n - 2$ .

Let us now consider a cnoidal wave with a contraction defect, as shown in the first row of Figure [17.](#page-27-0) This wave is constructed by extracting a symmetric interval around a trough between two neighbouring peaks and gluing the remaining parts together. Let us denote the period of the cnoidal wave by  $\ell$ . If we consider m peaks in the domain, then without the defect  $L = m\ell/2$ . With the defect, given that the length of the extracted symmetric interval is d, then  $L = (m\ell - d)/2$ . The resulting function has a corner at one point in the periodic domain  $[-L, L]$ , and the graph is symmetric about the vertical axis passing through that point. Let us denote this point by  $x_0$ . We can then associate the origin of the moving reference frame with  $x_0$ , i.e. assume  $x_0 = 0$ , and the function  $w_0 = u$  will be even in that frame. From the recurrence relation [\(A 10\)](#page-26-0), we observe that functions  $w_{2n}$  are even and  $w_{2n+1}$  are odd. Recalling that non-trivial conservation laws correspond to even values  $2n$ , we deduce from the recurrence relation [\(A 13\)](#page-26-1) that the corresponding fluxes  $f_{2n}$  can only contain terms representing even functions. Therefore,

$$
\frac{d}{dt}I_n = -\int_{-L}^{0} f_{2n}x dx - \int_{0}^{L} f_{2n}x dx
$$
\n(A14)

$$
= -\left[f_{2n}\right]_{-L}^{0} - \left[f_{2n}\right]_{0}^{L} = 0
$$
\n(A 15)

by periodicity and since the flux  $f_{2n}$  is an even function.

<span id="page-27-0"></span>

Figure 17: Schematic of construction of long-lived approximate and exact weak solutions of the KdV equation in the form of a cnoidal wave with a contraction and expansion periodicity defects (first and second rows, respectively), and a short-lived soliton with similar amplitude defects (third and fourth rows, respectively).

Similarly, we can consider a cnoidal wave with an expansion defect, as shown in the second row of Figure [17.](#page-27-0) This wave is constructed by cutting at a trough of the cnoidal wave between two peaks and symmetrically adding a segment of straight line at the corresponding level. (This can be generalised similarly to the contraction defect by first extracting a small part close to the trough, symmetrically inserting a segment of straight line and gluing the remaining parts to it. The resulting functions will also satisfy all conservation laws of the KdV equation.) Let the x-coordinates of the left and right endpoints of the line segment be denoted by  $x_1$  and  $x_2$ , respectively. We can choose our reference frame to have  $x_1 = -x_2 = -x_d$ . Consequently,

$$
\frac{d}{dt}I_n = -\int_{-L}^{-x_d} f_{2n_x} dx - \int_{-x_d}^{x_d} f_{2n_x} dx - \int_{x_d}^{L} f_{2n_x} dx
$$
\n(A16)

$$
= -\left[f_{2n}\right]_{-L}^{-x_d} - \left[f_{2n}\right]_{-x_d}^{x_d} - \left[f_{2n}\right]_{x_d}^{L} = 0 \tag{A.17}
$$

by periodicity, the constant value of  $f_{2n}$  on the interval  $[-x_d, x_d]$ , and since the flux  $f_{2n}$  is an even function.

Another way to proving the above relies on using that all non-trivial fluxes  $f_{2n}$  are polynomial functions of even weight with respect to the scaling symmetries of the KdV

equation. This also implies that the fluxes  $f_{2n}$  are even functions, and the rest follows from that.

Next, the KdV equation [\(4.1\)](#page-10-0) can be written in Lagrangian form

<span id="page-28-1"></span>
$$
\delta \int \mathcal{L} dx dt = 0, \quad \text{where} \quad \mathcal{L} = \frac{1}{2} \phi_t \phi_x - \phi_x^3 - \frac{1}{2} \phi_{xx}^2, \quad u = \phi_x. \tag{A.18}
$$

The weak solutions considered here are non-smooth travelling waves. Hence, the Lagrangian density [\(A 18\)](#page-28-1) becomes a function of u and  $u_x$ :  $\mathcal{L} = \mathcal{L}(u, u_x)$ . The Weirstrass-Erdmann corner conditions for broken extremals require the continuity of

$$
\frac{\partial \mathcal{L}}{\partial u_x} \quad \text{and} \quad \mathcal{L} - u_x \frac{\partial \mathcal{L}}{\partial u_x} \tag{A.19}
$$

at each junction (e.g. [Fox](#page-30-19) [1954\)](#page-30-19), which leads to the requirement of continuity of  $u_x$ , since u is continuous (see also [Gavrilyuk and Shyue](#page-30-23) [2022](#page-30-23) for a relevant discussion in the context of the Benjamin-Bona-Mahoney equation). This condition is satisfied exactly for a cnoidal wave with an expansion defect, and approximately for a cnoidal wave with a contraction defect, provided we cut close to extremum. The smoothed counterparts of cnoidal waves with both expansion and contraction defects were long-lived in our numerical simulations, with the former function behaving very close to a travelling wave solution. Therefore, it makes sense to view the corresponding functions are the exact and approximate weak travelling wave solutions of the KdV equation, respectively.

Having observed that the constructed weak solutions are long-lived (with the expansion defects possibly even stable), it is also temping to try to construct similar solutions by cutting around the peak rather than trough. In contrast to the previous cases, this can be done for a single peak as well, starting from the exact soliton solution, as shown in the third and fourth rows of Figure [17.](#page-27-0) However, in numerical runs, the smoothed counterparts of these solutions turned out to be unstable and short-lived, fissioning and giving rise to the usual solitons, in full agreement with the Inverse Scattering Transform (IST) predictions [\(Gardner et al.](#page-30-4) [1967,](#page-30-4) see also [Drazin and Johnson](#page-29-16) [1989\)](#page-29-16) for the respective smoothed initial conditions.

#### <span id="page-28-0"></span>**Appendix B.**

The Ostrovsky equation

$$
(u_T + \alpha_1 u u_{\zeta} + \beta_1 u_{\zeta \zeta \zeta})_{\zeta} = \gamma_1 u
$$
 (B 1)

is numerically solved by pseudospectral methods (see [Fornberg](#page-30-26) [1996;](#page-30-26) [Trefethen](#page-31-14) [2000\)](#page-31-14), which usually offer the highest accuracy and computational efficiency for smooth data on periodic domains. By implementing the Fast Fourier Transform (FFT) algorithm for spatial derivatives and the fourth-order Runge–Kutta scheme for time stepping, the method yields accurate approximation of the solution to the differential equation.

The spatial domain is discretised by M equidistant points with spacing  $\Delta x = 2\pi / M$ . Then, the discrete Fourier transform of the equation with respect to  $\zeta$  gives

$$
\hat{u}_T - i(k^3 \beta_1 - \frac{\gamma_1}{k})\hat{u} = -\frac{ik\alpha_1}{2}(\hat{u}^2),
$$

where  $k$  is the scaled wavenumber. We use the 4th-order Runge–Kutta scheme for temporal integration. By the integrating factor method of Kassam and Trefethen (e.g. [Trefethen](#page-31-14) [2000\)](#page-31-14), we multiply the equation by  $K = \exp[-i(k^3\beta_1 - \frac{\gamma_1}{k})T]$  to obtain

$$
\hat{U}_T = -\frac{ik\alpha_1}{2} K \mathcal{F}\{(\mathcal{F}^{-1} \Big[\frac{\hat{U}}{K}\Big])^2\},\
$$

where  $\hat{U} = \exp[-i(k^3\beta_1 - \frac{\gamma_1}{k})T]\hat{u} = K\hat{u}$  and  $\mathcal F$  is the Fourier transform. Discretising the time domain as  $T_n = n\Delta T$ , and introducing the function

$$
E = \exp[\frac{i}{2}(k^3\beta_1 - \frac{\gamma_1}{k})\Delta T],
$$

the optimised Runge–Kutta time stepping has the form

$$
\hat{u}^{(n+1)}=E^2\hat{u}^{(n)}+\frac{1}{6}[E^2k_1+2E(k_2+k_3)+k_4],
$$

where

$$
k_1 = -\frac{ik\alpha_1}{2}\Delta T \mathcal{F}\{(\mathcal{F}^{-1}[\hat{u}^{(n)}])^2\},
$$
  
\n
$$
k_2 = -\frac{ik\alpha_1}{2}\Delta T \mathcal{F}\{(\mathcal{F}^{-1}[E(\hat{u}^{(n)} + k_1/2)])^2\},
$$
  
\n
$$
k_3 = -\frac{ik\alpha_1}{2}\Delta T \mathcal{F}\{(\mathcal{F}^{-1}[E\hat{u}^{(n)} + k_2/2])^2\},
$$
  
\n
$$
k_4 = -\frac{ik\alpha_1}{2}\Delta T \mathcal{F}\{(\mathcal{F}^{-1}[E^2\hat{u}^{(n)} + Ek_3])^2\}.
$$
