

# APPROXIMATION OF GRADED BIALGEBRAS

GIOVANNA CARNOVALE, FRANCESCO ESPOSITO, LLEONARD RUBIO Y DEGRASSI

ABSTRACT. Motivated by an equivalence of categories established by Kapranov and Schechtman, we introduce, for each non-negative integer  $d$ , the category of connected bialgebras modulo  $d + 1$ . We show that these categories fit into an inverse system of categories whose inverse limit category is equivalent to the category of connected bialgebras. In addition, we extend the notion of approximation of connected bialgebras to those that are not necessarily generated in degree 1 and show that, for connected bialgebras in the category of Yetter-Drinfeld modules over a Hopf algebra, approximation is compatible with cocycle twisting.

## 1. INTRODUCTION

Connected bialgebras over a base field  $\mathbb{k}$  are  $\mathbb{N}$ -graded bialgebras, such that the degree 0 component is  $\mathbb{k}$ . Notable examples are: the tensor algebra, the cotensor (big shuffle) algebra and the symmetric algebra. This notion can be generalized if we replace the category of vector spaces by any additive  $\mathbb{k}$ -linear braided monoidal category  $\mathcal{V}$ : in this case key examples include the exterior algebra, cohomology algebras of simply-connected Lie groups, the positive part of quantized enveloping algebras, and, more generally, Nichols (shuffle) algebras. Since our main example of such a braided category is the category  $\mathcal{V} = {}^H_H\mathcal{YD}$  of Yetter-Drinfeld modules over a  $\mathbb{k}$ -Hopf algebra  $H$ , we concentrate on  $\mathbb{k}$ -linear categories  $\mathcal{V}$  whose objects are  $\mathbb{k}$ -vector spaces with possibly additional structure. In other words, we require that the category  $\mathcal{V}$  has a well-behaved functor to the category of  $\mathbb{k}$ -vector spaces. Most of the results we obtain could be formulated in a more general setting, to the cost of readability.

It has been recently shown by Kapranov and Schechtman in [13] that the category  $\mathcal{CB}(\mathcal{V})$  of connected bialgebras in  $\mathcal{V}$  has a geometric counterpart: it is equivalent to the category  $\mathcal{FP}(\text{Sym}(\mathbb{C}); \mathcal{V})$  of factorized perverse sheaves on the space  $\text{Sym}(\mathbb{C})$  of monic polynomials and with values in  $\mathcal{V}$ . One of our motivations is the translation of basic algebraic properties of connected bialgebras into geometric statements by means of this equivalence.

As one can see from the examples mentioned above, connected bialgebras may have very different nature: for instance, the symmetric and exterior algebra are quadratic, that is, they have a presentation with generators in degree 1 and homogeneous relations in degree 2; the positive part of the quantized enveloping algebra can be generated by degree 1 elements with relations up to a degree  $d > 2$  that depends on the Cartan matrix. Even for the well-studied class of Nichols algebras, there is no general method to determine a minimal set of homogeneous relations or to give a bound to the degree of such relations. It is then natural to investigate whether, for a connected bialgebra  $A$ , there is a  $d$  such that  $A$  has a (graded) presentation whose relations are bounded in degree  $d$ , and to estimate such a  $d$ . If the number of generators is finite, existence of such a bound is equivalent to  $A$  being finitely presented.

When a graded algebra  $A$  is generated in degree one, then one has a classical notion of  $d$ -atic cover, by considering the covering algebra whose relations are generated up to degree  $d$ . However, connected bialgebras such as the cotensor algebra or the cohomology ring of  $SU(n)$ , see Example 2.4 and Example 2.5, are not generated in degree one, and a more general approach is required to deal with them.

The first main goal of this paper is to generalize this construction to all connected bialgebras. In order to do so, we introduce the category of connected bialgebras modulo  $d + 1$  in  $\mathcal{V}$ , along with the  $d$ -th truncation and the  $d$ -th extension functors, and define the  $d$ -th approximation functor as a composition of the truncation and the extension functors. Our construction specializes to the classical procedure for bialgebras generated in degree one, (Theorem 3.11). Along the way, we prove that the  $d$ -th extension functor is left adjoint to the  $d$ -th truncation functor, see Proposition 3.7.

In addition, we show in Proposition 4.1 that when  $d$  runs in  $\mathbb{N}$ , the family of connected bialgebras modulo  $d + 1$  in  $\mathcal{V}$  fits into a system of categories whose inverse limit category, in the spirit of [22, §5.1], is equivalent to  $\mathcal{CB}(\mathcal{V})$ .

The second main goal of this work is to show that the  $d$ -th approximation functors are well-behaved with respect to equivalence of categories, (Theorem 5.1). In particular, if  $\mathcal{V} = {}^H_H\mathcal{YD}$  for a Hopf algebra  $H$  and  $\sigma$  is a left cocycle on  $H$ , then we exploit results in [2, 15] to show that the  $d$ -th approximation functors are well behaved with the equivalence induced by twisting  $H$  by  $\sigma$ , see Theorem 5.2. As a consequence, if two connected bialgebras  $A, A'$  are twist equivalent, then the same holds for their respective  $d$ -th approximations, and  $A$  coincides with its  $d$ -th approximation if and only if  $A'$  coincides with its  $d$ -th approximation.

This in particular holds for Nichols algebras, Corollary 5.3. In the Appendix A, we provide an alternative proof of Corollary 5.3 that does not require categorical machinery.

In the spirit of [13], in the forthcoming papers [4, 5] we will develop the geometric counterpart of the truncation and extension functors and establish an equivalence between the category of connected bialgebras modulo  $d + 1$  in  $\mathcal{V}$  and the category of factorized perverse sheaves on suitable open subspaces of  $\text{Sym}(\mathbb{C})$ . This allows the translation of algebraic statements about finite presentation and approximations of bialgebras into statements about perverse sheaves on  $\text{Sym}(\mathbb{C})$  that is our main motivation behind the introduction of the approximation functors.

## 2. BACKGROUND

**2.1. Bialgebras in braided categories.** With the purpose of fixing notation, we recall the definitions of monoidal category and braiding. The reader is referred to [8] for a complete treatment.

A monoidal category structure on a category  $\mathcal{C}$  is the datum of a bifunctor  $\otimes: \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$ , called tensor product, a natural isomorphism  $a: (- \otimes -) \otimes \rightarrow - \otimes (- \otimes -)$ , called the associativity constraint, an object  $\mathbf{1}_{\mathcal{C}}$  of  $\mathcal{C}$  called the unit object, and an isomorphism  $v: \mathbf{1}_{\mathcal{C}} \otimes \mathbf{1}_{\mathcal{C}} \rightarrow \mathbf{1}_{\mathcal{C}}$ , called unit constraint, subject to the pentagon and unit compatibility axioms [8, (2.2), (2.3)]. Notable examples are the category of  $\mathbb{k}$ -vector spaces, the category of representations of a Hopf algebra, the category of representations of a Lie algebra. A monoidal category is said to be strict if for all objects  $A, B, C$  in  $\mathcal{C}$  there are equalities  $(A \otimes B) \otimes C = A \otimes (B \otimes C)$  and  $A \otimes \mathbf{1}_{\mathcal{C}} = A = \mathbf{1}_{\mathcal{C}} \otimes A$  and the associativity and unit constraints are the identity maps.

Let  $\mathcal{C}, \mathcal{C}'$  be two monoidal categories with tensor products  $\otimes$  and  $\tilde{\otimes}$ , respectively. A monoidal functor from  $\mathcal{C}$  to  $\mathcal{C}'$  is a pair  $(\mathcal{F}, \omega)$ , where  $\mathcal{F}: \mathcal{C} \rightarrow \mathcal{C}'$  is a functor, and for all objects  $A, B \in \mathcal{C}$  we have that  $\omega_{A,B}: \mathcal{F}(A) \tilde{\otimes} \mathcal{F}(B) \rightarrow \mathcal{F}(A \otimes B)$  is a natural isomorphism such that  $\mathcal{F}(\mathbf{1}_{\mathcal{C}})$  is isomorphic to  $\mathbf{1}_{\mathcal{C}'}$  and such that  $(\mathcal{F}, \omega)$  satisfies the monoidal structure axiom [8, Equation 2.23]. A monoidal functor  $(\mathcal{F}, \omega)$  is strict if  $\omega_{A,B}$  and the isomorphism from  $(\mathbf{1}_{\mathcal{C}})$  to  $\mathbf{1}_{\mathcal{C}'}$  are identity maps for all objects  $A, B \in \mathcal{C}$ . A monoidal functor  $(\mathcal{F}, \omega)$  is a monoidal equivalence if  $\mathcal{F}$  is an equivalence of the underlying categories.

Given a monoidal category structure  $(\otimes, \mathbf{1}_{\mathcal{C}}, a, v)$  on  $\mathcal{C}$ , the opposite monoidal category structure on  $\mathcal{C}$  is given by the bifunctor  $\otimes^{op}$  such that  $A \otimes^{op} B := B \otimes A$  for any pair of objects  $A, B$  in  $\mathcal{C}$ , the associator  $a_{A,B,C}^{op} = a_{C,B,A}^{-1}$ , for any triple of objects  $A, B, C$  in  $\mathcal{C}$  together with  $\mathbf{1}_{\mathcal{C}}$ , and  $v$ . By Mac Lane's theorem, every monoidal category is monoidally equivalent to a strict one [8, Theorem 2.8.5], hence we will treat all monoidal categories as strict ones.

A braiding on a (strict) monoidal structure  $(\mathcal{C}, \otimes, \mathbf{1}_{\mathcal{C}})$  is an isomorphism of functors  $c: \otimes \rightarrow \otimes^{op}$  satisfying the following equations on triples of objects  $A, B$  and  $C$ :

$$c_{A,B \otimes C} = (\text{id}_B \otimes c_{A,C}) \circ (c_{A,B} \otimes \text{id}_C), \quad (2.1)$$

$$c_{A \otimes B, C} = (c_{A,C} \otimes \text{id}_B) \circ (\text{id}_A \otimes c_{B,C}) \quad (2.2)$$

Equation (2.1) imply the Yang-Baxter equation on  $\mathcal{C} \times \mathcal{C} \times \mathcal{C}$ :

$$(\text{id}_C \otimes c_{A,B}) \circ (c_{A,C} \otimes \text{id}_B) \circ (\text{id}_A \otimes c_{B,C}) = (c_{B,C} \otimes \text{id}_A) \circ (\text{id}_B \otimes c_{A,C}) \circ (c_{A,B} \otimes \text{id}_C). \quad (2.3)$$

A monoidal category with a braiding is a braided category. Let  $\mathcal{C}, \mathcal{C}'$  be two braided categories having tensor products  $\otimes, \tilde{\otimes}$  and braidings  $c, c'$ , respectively. A monoidal functor  $(\mathcal{F}, \omega)$  from  $\mathcal{C}$  to  $\mathcal{C}'$  is braided if  $\mathcal{F}(c_{A,B}) \circ \omega_{A,B} = \omega_{B,A} \circ c'_{\mathcal{F}(A), \mathcal{F}(B)}$  for all objects  $A, B$  in  $\mathcal{C}$ .

A braided monoidal equivalence of braided monoidal categories is a braided monoidal functor  $(\mathcal{F}, \omega)$  such that  $\mathcal{F}$  is an equivalence of the underlying categories.

The example of braided monoidal category we are mainly interested in is the category  ${}^H_H\mathcal{YD}$  of Yetter-Drinfeld modules over a Hopf algebra  $H$ . In order to give a concrete example we recall that, in the particular case in which  $H = \mathbb{k}G$  is the group algebra of a finite group, an object in  ${}^G_G\mathcal{YD}$  is a vector space  $V$  together with an action of  $G$  and a  $G$ -grading  $V = \bigoplus_{g \in G} V_g$  satisfying  $g \cdot V_h = V_{ghg^{-1}}$  for  $g, h \in G$ . The tensor product of objects in  ${}^G_G\mathcal{YD}$  is naturally equipped with a Yetter-Drinfeld module structure and the braiding on  $V \otimes W$  is given by  $c_{V,W}(v \otimes w) = h \cdot w \otimes v$  for every  $v \in V_h, h \in G$  and  $w \in W$ . We refer to [10, §3.4] for the definition of Yetter-Drinfeld modules and braiding in  ${}^H_H\mathcal{YD}$  for general  $H$ .

With this main example in mind, from now on  $\mathcal{V}$  will always denote an abelian,  $\mathbb{k}$ -linear braided category with a strict monoidal functor to the category of  $\mathbb{k}$ -vector spaces. Thus, we will regard its objects as vector spaces without further notice.

As in the category of vector spaces, one defines the notions of an algebra and a coalgebra in  $\mathcal{V}$ . An algebra in  $\mathcal{V}$  is an object  $A$  in  $\mathcal{V}$  together with an associative morphism  $m_A: A \otimes A \rightarrow A$  and a morphism  $\eta_A: \mathbf{1}_{\mathcal{V}} \rightarrow A$  satisfying the relation of a unit morphism on  $A$ , [10, (3.1.3), (3.1.4)]. Dually, a coalgebra in  $\mathcal{V}$  is an object  $C$  in  $\mathcal{V}$ , together with a coassociative morphism  $\Delta_C: C \rightarrow C \otimes C$  and a morphism  $\epsilon_C: C \rightarrow \mathbf{1}_{\mathcal{V}}$  satisfying a counit diagram, [1, §3.1]. Algebra, respectively, coalgebra morphisms are morphisms in  $\mathcal{V}$  that are compatible with the operation and the unit, respectively the counit.

Given two algebras (respectively coalgebras)  $A, B$  in  $\mathcal{V}$ , then  $A \otimes B$  is an algebra (respectively a coalgebra) in  $\mathcal{V}$  where the multiplication map (resp. comultiplication map) is defined as:  $m_{A \otimes B} = (m_A \otimes m_B) \circ (\text{id} \otimes c_{B,A} \otimes \text{id})$ ,  $\Delta_{A \otimes B} = (\text{id} \otimes c_{A,B} \otimes \text{id}) \circ (\Delta_A \otimes \Delta_B)$ . This allows to introduce the notion of a bialgebra in  $\mathcal{V}$ : assume that  $(A, m_A, \eta_A)$  is an algebra and  $(A, \Delta_A, \epsilon_A)$  a coalgebra in  $\mathcal{V}$ . Then  $(A, m_A, \eta_A, \Delta_A, \epsilon_A)$  is a bialgebra in  $\mathcal{V}$  if  $\Delta_A$  and  $\epsilon_A$  are algebra morphisms in  $\mathcal{V}$ .

We denote by  $m_A^{(n)} : A^{\otimes(n+1)} \rightarrow A$  the  $n$ -fold iteration of the multiplication, that is,  $m_A^{(1)} := m_A$  and for  $n > 1$  we define  $m_A^{(n)} := m_A^{(n-1)} \circ (m_A \otimes \text{id}^{(n-1)})$ . If  $f : A \rightarrow B$  is an algebra morphism, then  $m_B^{(n)} \circ f^{\otimes(n+1)} = f \circ m_A^{(n)}$  for every  $n \geq 1$ .

Let  $\mathbb{N}$  be the set of non-negative integers. Let  $\mathcal{V}_{gr}$  be the category of  $\mathbb{N}$ -graded objects in  $\mathcal{V}$ , that is, objects are of the form  $A = \bigoplus_{j \geq 0} A_j$  where each  $A_j$  is an object in  $\mathcal{V}$  and morphisms are homogeneous. It is not hard to verify that  $\mathcal{V}_{gr}$  is again braided monoidal, [21, Definition 2.1]. In more detail, for two objects  $A = \bigoplus_{j \geq 0} A_j$  and  $B = \bigoplus_{j \geq 0} B_j$  in  $\mathcal{V}_{gr}$ , we define  $A \otimes B$  where  $(A \otimes B)_n = \bigoplus_{i=0}^n A_i \otimes B_{n-i}$ ; the unit in  $\mathcal{V}_{gr}$  is given by the unit  $\mathbf{1}_{\mathcal{V}}$  in  $\mathcal{V}$  considered as an element concentrated in degree 0. The braiding in  $\mathcal{V}_{gr}$  is given by the sequence  $\varphi_{A,B} = (\bigoplus_{i+j=k} c_{A_i, B_j})_{k \geq 0}$ , where  $c_{A_i, B_j}$  is the braiding in  $\mathcal{V}$ .

We denote by  $\mathcal{CB}(\mathcal{V})$  the category of connected bialgebras, called primitive bialgebras in [13]. An object  $A = \bigoplus_{n \geq 0} A_n$  in  $\mathcal{CB}(\mathcal{V})$  is a bialgebra in  $\mathcal{V}_{gr}$ , that is, it is  $\mathbb{N}$ -graded as an algebra and a coalgebra, satisfying the additional connectedness condition  $A_0 = \mathbf{1}_{\mathcal{V}}$ .

**Example 2.1.** Let  $V$  be an object in  $\mathcal{V}$ . Setting  $T^m(V) := V^{\otimes m}$  for each  $m \geq 0$ , the object  $T(V) = \bigoplus_{m \geq 0} T^m(V)$  of  $\mathcal{V}_{gr}$  can be equipped with two natural connected bialgebra structures: the tensor algebra  $T_!(V)$ , with the usual tensor multiplication and comultiplication determined requiring that all elements in  $V$  are primitive; and the cotensor algebra  $T_*(V)$ , with the multiplication given by the braided shuffle product [10, Section 6.5] and comultiplication given by concatenation. When  $\mathcal{V}$  is the category of vector spaces with usual flip, the shuffle algebra structure was introduced in [20]. One defines the Nichols algebra  $\mathcal{B}(V)$  as the image of the unique graded algebra morphism  $\Omega : T_!(V) \mapsto T_*(V)$  which extends the identity on  $V$ . This morphism is also a coalgebra morphism hence  $\mathcal{B}(V)$  is an object in  $\mathcal{CB}(\mathcal{V})$ .

**Remark 2.2.** Let  $\mathcal{V}, \mathcal{V}'$  be two braided monoidal categories and let  $(\mathcal{T}, \omega)$  be a braided monoidal functor from  $\mathcal{V}$  to  $\mathcal{V}'$ . Since  $\mathcal{T}$  preserves bialgebras [10, Remark 3.2.13], then  $(\mathcal{T}, \omega)$  induces a functor from the category of bialgebras in  $\mathcal{V}$  to the category of bialgebras in  $\mathcal{V}'$ . In addition,  $(\mathcal{T}, \omega)$  induces a monoidal functor,  $(\overline{\mathcal{T}}, \overline{\omega})$  from  $\mathcal{V}_{gr}$  to  $\mathcal{V}'_{gr}$ . More precisely, let  $A = \bigoplus_{i \geq 0} A_i$  and  $B = \bigoplus_{j \geq 0} B_j$  be objects in  $\mathcal{V}_{gr}$ . We define  $\overline{\mathcal{T}}(A) := \bigoplus_{i \geq 0} \mathcal{T}(A_i)$  and for every morphism  $f = (f_i)_{i \geq 0} : A \rightarrow B$ , we define  $\overline{\mathcal{T}}(f) := (\mathcal{T}(f_i))_{i \geq 0}$ . Similarly,  $\overline{\omega}_{A,B} : \overline{\mathcal{T}}(A) \otimes \overline{\mathcal{T}}(B) \rightarrow \overline{\mathcal{T}}(A \otimes B)$  is a natural isomorphism defined by  $\overline{\omega}_{A,B} := \bigoplus_{i,j \geq 0} \omega_{A_i, B_j}$ . Moreover,  $(\overline{\mathcal{T}}, \overline{\omega})$  is a braided functor since  $(\mathcal{T}, \omega)$  is a braided functor. Therefore  $(\overline{\mathcal{T}}, \overline{\omega})$  induces a functor, which by abuse of notation is again denoted by  $\mathcal{T}$ , from  $\mathcal{CB}(\mathcal{V})$  to  $\mathcal{CB}(\mathcal{V}')$ . For  $A \in \mathcal{CB}(\mathcal{V})$  with multiplication  $m_A$  and comultiplication  $\Delta_A$ , the multiplication and comultiplication on  $\mathcal{T}(A)$  are defined, respectively, by  $\mathcal{T}(m_A) \circ \overline{\omega}_{A,A}$  and  $\overline{\omega}_{A,A}^{-1} \circ \mathcal{T}(\Delta_A)$ .

**Remark 2.3.** If  $\mathcal{V}$  is not symmetric, that is, if  $c \circ c \neq \text{id}_{\otimes}$ , then the tensor product of two bialgebras in  $\mathcal{V}$  is not necessarily a bialgebra. For example, let  $G$  be a group and let  $V_1, V_2$  be objects in the braided category  ${}_{\mathbb{k}G}^{\mathbb{k}G} \mathcal{YD}$  of Yetter-Drinfeld modules over  $\mathbb{k}G$ . Then

$\mathcal{B}(V_1) \otimes \mathcal{B}(V_2)$  is not always a bialgebra in  ${}_{\mathbb{k}G}^{\mathbb{k}G}\mathcal{YD}$ , see [10, Proposition 1.10.12, Corollary 1.6.10]. Hence,  $\mathcal{CB}(\mathcal{V})$  is not equipped with a monoidal structure if we consider the tensor product of algebras and coalgebras. It is also not  $\mathbb{k}$ -linear, nor additive.

Let  $\mathcal{CB}^1(\mathcal{V})$  be the full subcategory of  $\mathcal{CB}(\mathcal{V})$  whose objects are generated as algebras by their degree 1 component. An object  $B = \bigoplus_{j \geq 0} B_j$  in  $\mathcal{CB}^1(\mathcal{V})$  is then the quotient of  $T_!(B_1)$  by some graded ideal and coideal  $J$  contained in  $(\bigoplus_{m \geq 2} T_!^m(V))$ . For any  $d \in \mathbb{N}$ , the subspace  $\bigoplus_{m=2}^d (J \cap T_!^m(B_1))$  is a (possibly trivial) graded coideal of  $T_!(V)$ . Hence, the generated ideal  $(\bigoplus_{m=2}^d (J \cap T_!^m(B_1)))$  is a graded ideal and coideal. The bialgebra quotient

$$\widehat{B}_d := T_!(B_1) / \left( \bigoplus_{m=2}^d (J \cap T_!^m(B_1)) \right) \quad (2.4)$$

is again an object in  $\mathcal{CB}^1(\mathcal{V})$ . A morphism  $f: T_!(B_1)/J \rightarrow T_!(B'_1)/J'$  in  $\mathcal{CB}^1(\mathcal{V})$  is completely determined by its degree 1 component  $f_1: B_1 \rightarrow B'_1$ , which is necessarily a coalgebra morphism. Composing  $f_1$  with the natural inclusion  $B'_1 \subset T_!(B'_1)$  followed by the projection to  $\widehat{B}'_d$  gives a coalgebra morphism in  $\mathcal{V}_{gr}$ . The latter can be extended to a unique bialgebra morphism  $T_!(B_1) \rightarrow \widehat{B}'_d$  which factors through  $\widehat{B}_d$ . We denote the induced morphism by  $\widehat{f}_d$ . In this way we have defined an endofunctor  $\mathcal{CB}^1(\mathcal{V}) \rightarrow \mathcal{CB}^1(\mathcal{V})$  called the  $d$ -atic covering functor. For  $d = 2$ , the algebra  $\widehat{B}_d$  is the usual quadratic cover  $T_!(B_1)/(J \cap T_!^2(B_1))$ .

However, not all connected bialgebras are generated in degree one.

**Example 2.4.** Let  $V$  be a vector space. Then, the big shuffle algebra  $T_*(V)$  as in [20] is not generated in degree 1 as an algebra: indeed, for linearly independent  $v, w \in V$ , the element  $v \otimes w$  is not symmetric, hence it is not generated by elements in  $T^1(V) = V$ .

If  $A$  is the cohomology of a compact connected Lie group  $G$ , then  $A$  is a Hopf algebra in the category of  $\mathbb{N}$ -graded vector spaces with braiding given by  $c(v \otimes w) = (-1)^{pq} w \otimes v$ , where  $v$  and  $w$  have degree  $p, q$ , respectively, see [17] for the statement in terms of homology. In addition,  $A$  is isomorphic (as an algebra) to an exterior algebra on odd-dimensional generators [11]. These bialgebras give further examples of connected bialgebras that are not generated in degree one.

**Example 2.5.** [16, Example 5.F] [18, §6 Corollary 6.5] Assume that the characteristic of  $\mathbb{k}$  is 0. Then we have the following algebra isomorphisms:

- $H^*(SU(n); \mathbb{k}) \simeq \Lambda[x_3, x_5, \dots, x_{2n-1}]$ ;
- $H^*(SO(2m+1); \mathbb{k}) \simeq \Lambda[x_3, x_7, \dots, x_{4m-1}]$ ,

where the subscripts on the generators refer to their grading in the cohomology ring, that is,  $x_i \in H^i(G; \mathbb{k})$ .

**2.2. Duality.** Let  $V$  be an object of a braided monoidal category  $\mathcal{V}$ . A left dual of  $V$  is a triple  $(V^*, \text{ev}_V, \text{coev}_V)$ , where  $V^*$  is an object of  $\mathcal{C}$ ,  $\text{ev}_V: V^* \otimes V \rightarrow \mathbf{1}_{\mathcal{C}}$  and  $\text{coev}_V: \mathbf{1}_{\mathcal{C}} \rightarrow V \otimes V^*$  are morphisms such that  $(\text{ev}_V \otimes \text{id}) \circ (\text{id} \otimes \text{coev}_V) = \text{id}_{V^*}$ ,  $(\text{id} \otimes \text{ev}_V) \circ (\text{coev}_V \otimes \text{id}) = \text{id}_V$ .

A braided category  $\mathcal{V}$  is called rigid if each object has a left dual. The prototypical examples of rigid braided monoidal categories are the category of finite-dimensional vector spaces and the category of finite-dimensional Yetter-Drinfeld modules over a Hopf algebra

[10, Remark 4.2.4]. If  $\mathcal{V}$  is rigid, then for any morphism  $f: V \rightarrow W$  one defines the left dual  $f^*: W^* \rightarrow V^*$  as  $f^* = (\text{ev}_W \otimes \text{id}_{V^*})(\text{id}_{W^*} \otimes f \otimes \text{id}_{V^*})(\text{id}_{W^*} \otimes \text{coev}_V)$ , see [10, Remark 3.5.2]. The contravariant functor  $(-)^*: \mathcal{V} \rightarrow \mathcal{V}$ , which sends an object  $V$  to  $V^*$  and maps a morphism  $f$  to  $f^*$  is called the left duality functor.

There is a natural isomorphism from the identity functor to  $(-)^{**}$ , see [10, Theorem 3.5.8]. In addition,  $\mathcal{V}_{gr}$  is also rigid, by taking the graded dual, i.e., for an object  $A = \bigoplus_{j \geq 0} A_j$  in  $\mathcal{V}_{gr}$ , the dual  $A^*$  is  $\bigoplus_{j \geq 0} A_j^*$  and for a morphism  $f: A \rightarrow B$ , the morphism  $f^*: B^* \rightarrow A^*$  is defined as  $(f_j^*)_{j \geq 0}$ .

More generally, a duality in a category  $\mathcal{A}$  is a contravariant functor  $\mathbb{D}: \mathcal{A} \rightarrow \mathcal{A}$  with a quasi-inverse. For example, the left duality functor in  $\mathcal{V}_{gr}$  as above induces a duality on  $\mathcal{CB}(\mathcal{V})$ , as the dual of a bialgebra in a braided monoidal category is again a bialgebra, see [10, Remark 3.5.9].

Let  $\mathcal{A}$  and  $\mathcal{B}$  be categories with dualities  $\mathbb{D}, \mathbb{D}'$ , respectively and let  $G: \mathcal{A} \rightarrow \mathcal{B}$  be a functor. Then the dual functor  $\overline{\mathbb{D}}$  of  $G$  is a functor from  $\mathcal{A}$  to  $\mathcal{B}$  defined on objects as  $\overline{\mathbb{D}}G(A) := \mathbb{D}'(G(\mathbb{D}A))$  and on morphisms  $f: A \rightarrow B$  as  $\overline{\mathbb{D}}G(f) := \mathbb{D}'(G(\mathbb{D}f))$ .

### 3. APPROXIMATION FUNCTOR

The goal of this section is to define the  $d$ -th approximation functor  $F_d$  on the category of connected bialgebras, as a composition of two adjoint functors: the truncation functor  $\Theta_d$  and the extension functor  $\Psi_d$ . We first need to introduce a truncated version of  $\mathcal{CB}(\mathcal{V})$ .

**3.1. Connected bialgebras modulo  $d+1$ .** Let  $d \in \mathbb{N}$ . For an object  $V = \bigoplus_{j \geq 0} V_j$  in  $\mathcal{V}_{gr}$  its  $d$ -th truncation is the object  $V_{\leq d} := \bigoplus_{j \leq d} V_j$  in  $\mathcal{V}_{gr}$ . Similarly, for a morphism  $f = (f_j)_{j \in \mathbb{N}}: A \rightarrow A'$  in  $\mathcal{V}_{gr}$ , its truncation  $f_{\leq d}$  is the morphism  $(f_j)_{0 \leq j \leq d}: A_{\leq d} \rightarrow A'_{\leq d}$ .

**Definition 3.1.** *A connected bialgebra mod  $d+1$  is an algebra and coalgebra  $A = \bigoplus_{l=0}^d A_l$  in  $\mathcal{V}_{gr}$ , such that  $A_0 = \mathbf{1}_{\mathcal{V}}$ , and such that the multiplication  $m_A$  and the comultiplication  $\Delta_A$  satisfy the following compatibility relation:*

$$\begin{array}{ccc}
(A \otimes A)_{\leq d} & \xrightarrow{(m_A)_{\leq d}} & A_{\leq d} \\
(\Delta_A \otimes \Delta_A)_{\leq d} \downarrow & & \downarrow (\Delta_A)_{\leq d} \\
(A \otimes A \otimes A \otimes A)_{\leq d} & & (A \otimes A)_{\leq d} \\
& \searrow (\text{id} \otimes c_{A,A} \otimes \text{id})_{\leq d} & \nearrow (m_A \otimes m_A)_{\leq d} \\
& (A \otimes A \otimes A \otimes A)_{\leq d} & 
\end{array} \tag{3.5}$$

The category  $\mathcal{CB}^{\leq d}(\mathcal{V})$  of connected bialgebras mod  $d+1$  is the category whose objects are connected bialgebras mod  $d+1$  and whose morphisms are graded coalgebra maps preserving the multiplication.

In other words, objects in  $\mathcal{CB}^{\leq d}(\mathcal{V})$  satisfy the bialgebra compatibility condition up to degree  $d$ .

**Example 3.1.** Let  $A = \bigoplus_{i=0}^d A_i \in \mathcal{CB}(\mathcal{V})$ , with comultiplication  $\Delta_A$  and multiplication  $m_A$ .

- (1) If  $d = 0$ , then  $\mathcal{CB}^{\leq 0}(\mathcal{V})$  is the category consisting of only the unit object  $\mathbf{1}_{\mathcal{V}}$  and the identity morphism.
- (2) If  $d \geq 1$ , then for any  $a \in A_1, b \in A_d$  we have  $\Delta(a) = a \otimes 1 + 1 \otimes a$  and  $m_A(a \otimes b) = 0$ .
- (3) If  $d = 1$ , then  $m_A$  is trivial on  $A_1 \otimes A_1$ , and on  $A_0 \otimes A_1$  and  $A_1 \otimes A_0$  is scalar multiplication. Hence the assignment  $A \mapsto A_1$  determines an equivalence of categories  $\mathcal{CB}^{\leq 1}(\mathcal{V}) \simeq \mathcal{V}$ .
- (4) If  $d = 2$ , then  $\mathcal{CB}^{\leq 2}(\mathcal{V})$  is equivalent to the category whose objects are quadruples  $(V_1, V_2, \mu, \delta)$ , where  $V_1, V_2$  are objects in  $\mathcal{V}$ , and  $\mu: V_1 \otimes V_1 \rightarrow V_2$  and  $\delta: V_2 \rightarrow V_1 \otimes V_1$  are morphisms satisfying  $\delta\mu(a \otimes b) = a \otimes b + c_{V_1, V_1}(b \otimes a)$  for all  $a, b \in A_1$ . A morphism from  $(V_1, V_2, \mu, \delta)$  to  $(W_1, W_2, \mu', \delta')$  is given by a pair  $(f_1, f_2)$  of maps  $f_1: V_1 \rightarrow W_1, f_2: V_2 \rightarrow W_2$  such that  $f_2(\mu(a \otimes b)) = \mu'(f_1(a) \otimes f_1(b))$  and such that  $\delta'(f_2(c)) = (f_1 \otimes f_1)(\delta(c))$  for any  $a, b \in V_1$  and  $c \in V_2$ .

**Remark 3.2.** Let  $\mathcal{V}, \mathcal{V}'$  be two braided monoidal categories and let  $(\mathcal{T}, \omega)$  be a braided monoidal functor from  $\mathcal{V}$  to  $\mathcal{V}'$ . Let  $(\overline{\mathcal{T}}, \overline{\omega})$  be the induced braided monoidal functor from  $\mathcal{V}_{gr}$  to  $\mathcal{V}'_{gr}$ . As for connected bialgebras,  $(\overline{\mathcal{T}}, \overline{\omega})$  induces a functor, denoted by  $\mathcal{T}^d$ , from  $\mathcal{CB}^{\leq d}(\mathcal{V})$  to  $\mathcal{CB}^{\leq d}(\mathcal{V}')$ . For an algebra  $A$  in  $\mathcal{CB}^{\leq d}(\mathcal{V})$  with multiplication  $m_A$  and comultiplication  $\Delta_A$ , the multiplication and comultiplication on  $\mathcal{T}^d(A)$  are defined, respectively, by  $\mathcal{T}^d(m_A) \circ \overline{\omega}_{A,A}$  and  $\overline{\omega}_{A,A}^{-1} \circ \mathcal{T}^d(\Delta_A)$ . In addition,  $\overline{\mathcal{T}}(A)$  satisfies the bialgebra compatibility condition up to degree  $d$  because  $A$  does and  $\overline{\mathcal{T}}$  is a graded braided monoidal functor.

**Remark 3.3.** As for ordinary bialgebras, the notion of bialgebra modulo  $d + 1$  is self-dual. Indeed, if  $\mathcal{V}$  is rigid and  $A = \bigoplus_{l=0}^d A_l$  is an object in  $\mathcal{CB}^{\leq d}(\mathcal{V})$ , then  $A^* = \bigoplus_{l=0}^d A_l^*$  is a graded algebra and a graded coalgebra satisfying  $A_0^* = \mathbf{1}_{\mathcal{V}}$ . In addition, [10, Theorem 3.5.8] ensures the existence of natural isomorphisms

$$\varphi_{V,W}: V^* \otimes W^* \rightarrow (V \otimes W)^*,$$

for any  $V$  and  $W$  in  $\mathcal{V}$ , so for each  $l \geq 0$  there is an isomorphism

$$\varphi_l = \bigoplus_{i+j=l} \varphi_{i,j}: \bigoplus_{i+j=l} A_i^* \otimes A_j^* \rightarrow \left( \bigoplus_{i+j=l} A_i \otimes A_j \right)^*.$$

Combining  $\varphi_l: (A^* \otimes A^*)_l \rightarrow (A \otimes A)_l^*$  for  $0 \leq l \leq d$  gives an isomorphism

$$\varphi_{\leq d} = \bigoplus_{0 \leq l \leq d} \varphi_l: (A^* \otimes A^*)_{\leq d} \rightarrow (A \otimes A)_{\leq d}^*.$$

Making use of  $\varphi_{\leq d}$  the diagram (3.5) dualizes as:

$$\begin{array}{ccc}
(A^* \otimes A^*)_{\leq d} & \xleftarrow{(\Delta_{A^*})_{\leq d}} & (A^*)_{\leq d} \\
\uparrow (m_{A^* \otimes A^*})_{\leq d} & & (m_{A^*})_{\leq d} \uparrow \\
(A^* \otimes A^* \otimes A^* \otimes A^*)_{\leq d} & \xleftarrow{(\text{id} \otimes c_{A^*, A^*} \otimes \text{id})_{\leq d} \quad (\Delta_{A^*} \otimes \Delta_{A^*})_{\leq d}} & (A^* \otimes A^*)_{\leq d} \\
& & \downarrow \\
& & (A^* \otimes A^* \otimes A^* \otimes A^*)_{\leq d}
\end{array}$$

because  $c_{W,V} \circ \varphi_{V,W} = \varphi_{W,V} \circ c_{V^*,W^*}$  for all pairs of objects  $V, W$  in  $\mathcal{V}$ , [10, Theorem 3.5.8]. Hence,  $A^*$  is an object in  $\mathcal{CB}^{\leq d}(\mathcal{V})$  and in virtue of loc. cit., the left duality functor in  $\mathcal{V}_{gr}$  induces a duality on  $\mathcal{CB}^{\leq d}(\mathcal{V})$  for any  $d \geq 0$  that we denote by  $\mathbb{D}_d$ .

**3.2. The truncation functor.** Let  $d \in \mathbb{N}$ , let  $A = \bigoplus_{j \geq 0} A_j$  be an object in  $\mathcal{CB}(\mathcal{V})$  with coproduct  $\Delta_A$ , counit  $\epsilon_A$  and multiplication  $m_A$ , and let  $A_{\leq d} \in \mathcal{V}_{gr}$ . The restriction of  $\epsilon_A$  and  $\Delta_A$  to  $A_{\leq d}$  equips it with a graded coalgebra structure. Since  $A_{\leq d}$  identifies with  $A / \bigoplus_{j > d} A_j$  as objects in  $\mathcal{V}_{gr}$  and  $A_{> d} := \bigoplus_{j > d} A_j$  is a graded ideal, the restriction of  $m_A$  to  $A_{\leq d} \otimes A_{\leq d}$  equips  $A_{\leq d}$  with a graded algebra structure. We denote by  $\Theta_d(A)$  the algebra and coalgebra obtained this way, and by  $m_{\Theta_d(A)}$ ,  $\Delta_{\Theta_d(A)}$  and  $\epsilon_{\Theta_d(A)}$  its multiplication, comultiplication and counit. Let  $i, j \in \mathbb{N}$  such that  $i + j \leq d$ . With the appropriate identifications, we have equality for the restrictions:  $m_A|_{A_i \otimes A_j} = m_{\Theta_d(A)}|_{A_i \otimes A_j}$ ,  $\epsilon_A|_{A_i} = \epsilon_{\Theta_d(A)}|_{A_i}$ ,  $\Delta_A|_{A_i} = \Delta_{\Theta_d(A)}|_{A_i}$ , and  $c_{A,A}|_{A_i \otimes A_j} = c_{\Theta_d(A), \Theta_d(A)}|_{A_i \otimes A_j}$ . Therefore, (3.5) is verified for  $\Theta_d(A)$ . In addition, the truncation  $(\ )_{\leq d}$  of any morphism  $f: A \rightarrow A'$  in  $\mathcal{CB}(\mathcal{V})$  gives a morphism  $\Theta_d(f)$  in  $\mathcal{CB}(\mathcal{V})$ , so  $\Theta_d$  is a covariant functor  $\mathcal{CB}(\mathcal{V}) \rightarrow \mathcal{CB}^{\leq d}(\mathcal{V})$  which we call the  $d$ -th truncation functor.

**Remark 3.2.** If  $\mathcal{V}$  is rigid, then the truncation functor  $\Theta_d$  and the dual functors  $\mathbb{D}: \mathcal{CB}(\mathcal{V}) \rightarrow \mathcal{CB}(\mathcal{V})$ ,  $\mathbb{D}_d: \mathcal{CB}^{\leq d}(\mathcal{V}) \rightarrow \mathcal{CB}^{\leq d}(\mathcal{V})$  are compatible, i.e.,  $\Theta_d \circ \mathbb{D} = \mathbb{D}_d \circ \Theta_d$ , that is,  $\Theta_d$  is self-dual. Indeed, for  $A = \bigoplus_{i \geq 0} A_i$  in  $\mathcal{CB}(\mathcal{V})$ , then  $\Theta_d \circ \mathbb{D}(A) = \Theta_d(\bigoplus_{i \geq 0} A_i^*) = \bigoplus_{i=0}^d A_i^* = \mathbb{D}_d(\bigoplus_{i=0}^d A_i) = \mathbb{D}_d \circ \Theta_d(A)$  at the level of objects in  $\mathcal{V}_{gr}$ , and similarly for morphisms, since evaluation and coevaluation maps are obtained graded component by graded component. Moreover,  $\Delta_{\mathbb{D}_d \Theta_d(A)} = m_{\Theta_d(A)}^* = m_{\Theta_d(\mathbb{D}_d A)}^* = \Delta_{\Theta_d(\mathbb{D}_d(A))}$ , and similarly for  $m_{\mathbb{D}_d \Theta_d(A)}$ , giving the equality at the level of objects in  $\mathcal{CB}(\mathcal{V})$ . A similar argument applies to morphisms.

**3.3. The extension functor.** In order to define the extension functors, we need to generalize Radford's construction of the free bialgebra over a coalgebra from [19, Section 5.3] to the braided setting. Possibly passing to a completion, we assume that  $\mathcal{V}$  is closed under countable direct sums.

Let  $(C, \Delta_C, \epsilon_C)$  be a coalgebra in  $\mathcal{V}$  and let  $T(C) = \bigoplus_{j \geq 0} C^{\otimes j}$  be equipped with the tensor algebra structure, so  $T(C) \otimes T(C)$  is an algebra in  $\mathcal{V}$  as in Section 2.1. Let  $\iota: C \rightarrow T(C)$  be the canonical inclusion. By the universal property of  $T(C)$ , there are unique algebra morphisms  $\epsilon_{T(C)}: T(C) \rightarrow \mathbb{k}$  and  $\Delta_{T(C)}: T(C) \rightarrow T(C) \otimes T(C)$  in  $\mathcal{V}$  extending  $\epsilon_C \circ \iota$  and  $(\iota \otimes \iota) \circ \Delta_C$ . This way  $T(C)$  becomes a bialgebra in  $\mathcal{V}$  enjoying the following universal property.

**Proposition 3.3.** *Let  $C$  be a coalgebra in  $\mathcal{V}$ . For any bialgebra  $A$  in  $\mathcal{V}$  and any coalgebra morphism  $f: C \rightarrow A$  there is a unique bialgebra morphism  $\tilde{f}: T(C) \rightarrow A$  satisfying  $\tilde{f} \circ \iota = f$ .*

*Proof.* This is proved exactly as [19, Theorem 5.3.1 (b)]. □

By construction  $\iota$  is a one-to-one coalgebra morphism, so from now on we will identify  $C$  and its image in  $T(C)$  neglecting  $\iota$ . With this identification  $C \otimes C$  becomes a subcoalgebra of  $T(C) \otimes T(C)$  because the restriction of the braiding  $c_{T(C), T(C)}$  to  $C \otimes C$  coincides with  $c_{C, C}$ . We observe that if  $C = \bigoplus_{j \geq 0} C_j$  is a coalgebra in  $\mathcal{V}_{gr}$ , then  $T(C)$  is a bialgebra in  $\mathcal{V}_{gr}$  where  $T(C)_l = \bigoplus_{j \geq 0} (C^{\otimes j})_l$ .

Let now  $d \in \mathbb{N}$  and let  $A = \bigoplus_{l=0}^d A_l$  be an object in  $\mathcal{CB}^{\leq d}(\mathcal{V})$ . Note that the tensor algebra  $T(A)$  over  $A$  regarded as a coalgebra is not connected, as in degree 0 we have  $\mathbf{1}_{\mathcal{V}} \oplus (\bigoplus_{j \geq 1} A_0^{\otimes j})$ . However, the elements  $\mathbf{1}_{\mathbb{k}} \in \mathbf{1}_{\mathcal{V}} = A^{\otimes 0}$  and  $\mathbf{1}_A^{\otimes j} \in A_0^{\otimes j}$  for  $j \geq 1$  are all grouplike.

Denoting the multiplication in  $A$  and  $T(A)$ , by  $m_A$  and  $m_{T(A)}$ , respectively, we consider the algebra ideal  $J_A = ((m_{T(A)} - m_A)(A \otimes A)_{\leq d}, \mathbb{k}(\mathbf{1}_{\mathbb{k}} - \mathbf{1}_A))$  in  $T(A)$ .

**Proposition 3.4.** *With notation as above,  $J_A$  is a coideal of  $T(A)$ .*

*Proof.* First of all,  $\Delta_{T(A)}(\mathbf{1}_{\mathbb{k}} - \mathbf{1}_A) \in T(A)_0 \otimes J_A + J_A \otimes T(A)_0$  and  $\epsilon_{T(A)}(\mathbf{1}_{\mathbb{k}} - \mathbf{1}_A) = 0$  because the difference of two grouplikes  $g$  and  $h$  in a coalgebra is always  $(g, h)$ -primitive. Hence,  $\mathbb{k}(\mathbf{1}_{\mathbb{k}} - \mathbf{1}_A)$  is a coideal. Observe now that  $(A \otimes A)_{\leq d}$  is a subcoalgebra of  $A \otimes A$ , whence of  $T(A) \otimes T(A)$ . By (3.5) the morphism  $(m_A)_{\leq d}$  gives a coalgebra morphism  $(A \otimes A)_{\leq d} \rightarrow A_{\leq d} \subset A \subset T(A)$ . The restriction of  $m_{T(A)}$  to  $(A \otimes A)_{\leq d}$  is also a coalgebra morphism because  $T(A)$  is a bialgebra. Since by [19, Exercise 2.1.29] the image of the difference of two coalgebra morphisms is a coideal,  $(m_A - m_{T(A)})(A \otimes A)_{\leq d}$  is a coideal in  $T(A)$ . Hence,  $J_A = ((m_A - m_{T(A)})(A \otimes A)_{\leq d}, \mathbb{k}(\mathbf{1}_{\mathbb{k}} - \mathbf{1}_A))$  is a coideal in  $T(A)$ .  $\square$

It follows from Proposition 3.4 that  $\Psi_{dl}(A) := T(A)/J_A$  is a graded bialgebra, with grading inherited from  $A$ , and that  $(T(A)/J_A)_0 \simeq \mathbb{k}$ . Hence  $\Psi_{dl}(A)$  is an object in  $\mathcal{CB}(\mathcal{V})$ .

Composing a morphism  $f: A \rightarrow A'$  in  $\mathcal{CB}^{\leq d}(\mathcal{V})$  with the natural inclusion  $A' \subset T(A')$  gives coalgebra morphism in  $\mathcal{V}_{gr}$ , which extends to a bialgebra morphism  $T(f)$  by Proposition 3.3 applied to  $A$  and  $T(A')$ . By construction  $T(f)$  is graded.

**Lemma 3.5.** *Let  $A, A'$  be in  $\mathcal{CB}^{\leq d}(\mathcal{V})$  and let  $f: A \rightarrow A'$  be a morphism in  $\mathcal{CB}^{\leq d}(\mathcal{V})$ . The bialgebra morphism  $T(f): T(A) \rightarrow T(A')$  maps the ideal  $J_A$  into  $J_{A'}$ .*

*Proof.* By construction,  $T(f)(\mathbf{1}_{\mathbb{k}} - \mathbf{1}_A) = \mathbf{1}_{\mathbb{k}} - f(\mathbf{1}_A) = \mathbf{1}_{\mathbb{k}} - \mathbf{1}_{A'} \in J_{A'}$ . In addition,

$$\begin{aligned} T(f)(m_A - m_{T(A)})(A \otimes A)_{\leq d} &= (f \circ m_A - T(f) \circ m_{T(A)})(A \otimes A)_{\leq d} \\ &= (m_{A'}(f \otimes f) - m_{T(A')}(T(f) \otimes T(f)))(A \otimes A)_{\leq d} \\ &= (m_{A'} - m_{T(A')})(f \otimes f)(A \otimes A)_{\leq d} \\ &\subset (m_{A'} - m_{T(A')})(A' \otimes A')_{\leq d} \subset J_{A'}, \end{aligned}$$

where we have used that  $f$  coincides with  $T(f)$  on  $m_A(A \otimes A)_{\leq d}$ , that  $f$  and  $T(f)$  are algebra morphisms, that  $(A \otimes A)_{\leq d} \subseteq A_{\leq d} \otimes A_{\leq d}$ , and that  $f \otimes f$  is graded.  $\square$

For any morphism  $f: A \rightarrow A'$  in  $\mathcal{CB}^{\leq d}(\mathcal{V})$  we then set  $\Psi_{dl}(f): \Psi_{dl}(A) \rightarrow \Psi_{dl}(A')$  to be the bialgebra morphism induced by  $T(f)$ . It is not hard to verify that

$$\Psi_{dl}: \mathcal{CB}^{\leq d}(\mathcal{V}) \rightarrow \mathcal{CB}(\mathcal{V})$$

is a covariant functor, we call it the  $d$ -th extension functor.

**3.4. An adjunction.** Let  $d \in \mathbb{N}$ , let  $A \in \mathcal{CB}^{\leq d}(\mathcal{V})$  and let  $\eta_A: A \rightarrow \Psi_{d!}(A)$  be the composition of the inclusion  $A \subset T(A)$  with the canonical projection  $T(A) \rightarrow \Psi_{d!}(A)$ .

For  $f \in \text{Hom}_{\mathcal{CB}(\mathcal{V})}(\Psi_{d!}(A), B)$ , the composition  $f \circ \eta_A: A \rightarrow B$  is a graded coalgebra morphism with image in  $B_{\leq d}$ . Now,

$$\begin{aligned} f \circ \eta_A \circ m_A|_{(A \otimes A)_l} &= 0 = m_{\Theta_d(B)}((f \circ \eta_A) \otimes (f \circ \eta_A))|_{(A \otimes A)_l} && \text{if } l > d, \text{ and} \\ f \circ \eta_A \circ m_A|_{(A \otimes A)_{\leq d}} &= f \circ m_{\Psi_{d!}(A)} \circ (\eta_A \otimes \eta_A)|_{(A \otimes A)_{\leq d}} \\ &= m_B \circ ((f \circ \eta_A) \otimes (f \circ \eta_A))|_{(A \otimes A)_{\leq d}} \\ &= m_{\Theta_d(B)} \circ ((f \circ \eta_A) \otimes (f \circ \eta_A))|_{(A \otimes A)_{\leq d}}. \end{aligned}$$

Hence,  $(f \circ \eta_A)_{\leq d}$  lies in  $\text{Hom}_{\mathcal{CB}^{\leq d}}(A, \Theta_d(B))$ . We set

$$\begin{aligned} \Xi_{AB}: \text{Hom}_{\mathcal{CB}(\mathcal{V})}(\Psi_{d!}(A), B) &\longrightarrow \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V})}(A, \Theta_d(B)) \\ f &\mapsto (f \circ \eta_A)_{\leq d}. \end{aligned} \quad (3.6)$$

Let now  $g \in \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V})}(A, \Theta_d(B))$ . The composition of  $g$  with the coalgebra inclusion  $\tau_B: \Theta_d(B) \subset B$  extends to a bialgebra morphism  $\widetilde{\tau_B \circ g}: T(A) \rightarrow B$  by Proposition 3.3.

**Lemma 3.6.** *With the above notation, the bialgebra morphism  $\widetilde{\tau_B \circ g}: T(A) \rightarrow B$  factors through  $\Psi_{d!}(A)$ .*

*Proof.* First of all  $\tau_B g(1_A) = 1_B$  because  $g$  is a morphism in  $\mathcal{CB}^{\leq d}(\mathcal{V})$ , and  $\widetilde{\tau_B \circ g}(1_{\mathbb{k}}) = 1_B$  because  $\widetilde{\tau_B \circ g}$  is a bialgebra morphism, hence  $\widetilde{\tau_B \circ g}(1_A - 1_{\mathbb{k}}) = 0$ . Moreover,

$$\begin{aligned} \widetilde{\tau_B \circ g}(m_A - m_{T(A)})(A \otimes A)_{\leq d} &= (\tau_B \circ g \circ m_A - \widetilde{\tau_B \circ g} \circ m_{T(A)})(A \otimes A)_{\leq d} \\ &= m_B \circ (((\tau_B \circ g) \otimes (\tau_B \circ g)) - (\widetilde{\tau_B \circ g} \otimes \widetilde{\tau_B \circ g}))(A \otimes A)_{\leq d} = 0 \end{aligned}$$

where we have used that  $\widetilde{\tau_B \circ g}$  is an algebra morphism extending  $\tau_B \circ g$  on  $A$ .  $\square$

Let  $\bar{g}: \Psi_{d!}(A) \rightarrow B$  be the morphism induced by  $\widetilde{\tau_B \circ g}: T(A) \rightarrow B$ . We set

$$\begin{aligned} \Gamma_{AB}: \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V})}(A, \Theta_d(B)) &\longrightarrow \text{Hom}_{\mathcal{CB}(\mathcal{V})}(\Psi_{d!}(A), B) \\ g &\mapsto \bar{g}. \end{aligned} \quad (3.7)$$

**Proposition 3.7.** *Let  $d \geq 0$ . The maps  $\Xi_{AB}$  for  $A \in \mathcal{CB}^{\leq d}(\mathcal{V})$  and  $B \in \mathcal{CB}(\mathcal{V})$  combine to give a natural isomorphism*

$$\Xi: \text{Hom}_{\mathcal{CB}(\mathcal{V})}(\Psi_{d!}(\cdot), \cdot) \longrightarrow \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V})}(\cdot, \Theta_d(\cdot)) \quad (3.8)$$

whose inverse is  $\Gamma = (\Gamma_{AB})$ . Hence,  $\Psi_{d!}$  is left adjoint to  $\Theta_d$ .

*Proof.* Naturality in  $A$  and  $B$  follows from commutativity of the diagrams

$$\begin{array}{ccc} A' \xrightarrow{\eta_{A'}} T(A') & \longrightarrow & \Psi_{d!}(A') \\ \varphi \downarrow & & \downarrow \Psi_{d!}(\varphi) \\ A \xrightarrow{\eta_A} T(A) & \longrightarrow & \Psi_{d!}(A) \end{array} \quad \begin{array}{ccc} B & \xrightarrow{\psi} & B' \\ \downarrow & & \downarrow \\ \Theta_d(B) & \xrightarrow{\Theta_d(\psi)} & \Theta_d(B') \end{array}$$

for any  $\psi \in \text{Hom}_{\mathcal{CB}(\mathcal{V})}(B, B')$  and any  $\varphi \in \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V})}(A', A)$ , where the vertical arrows in the diagram on the right are the natural projections. Let  $f \in \text{Hom}_{\mathcal{CB}(\mathcal{V})}(\Psi_{d!}(A), B)$  and

$g \in \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V})}(A, \Theta_d(B))$ . Then,  $\Gamma_{AB}\Xi_{AB}(f) = f$  and  $\Xi_{AB}\Gamma_{AB}(g) = g$  by commutativity of the diagrams below.

$$\begin{array}{ccc}
A & \xrightarrow{\Xi(f)} & B_{\leq d} \xrightarrow{\tau_B} B \\
\downarrow & \nearrow & \uparrow f \\
T(A) & \xrightarrow{\tau_B \circ \Xi(f)} & \Psi_{d!}(A)
\end{array}
\qquad
\begin{array}{ccc}
A & \xrightarrow{g} & B_{\leq d} \xrightarrow{\tau_B} B \\
\downarrow & \nearrow & \uparrow \Gamma(g) \\
T(A) & \xrightarrow{\tau_B \circ g} & \Psi_{d!}(A)
\end{array}$$

□

Assume that  $\mathcal{V}$  is rigid so  $\mathcal{CB}(\mathcal{V})$  and  $\mathcal{CB}^{\leq d}(\mathcal{V})$  have a duality, cf. Remark 3.3 and Subsection 2.2. We denote by  $\Psi_{d*} := \overline{\mathbb{D}}(\Psi_{d!})$  the functor from  $\mathcal{CB}^{\leq d}(\mathcal{V})$  to  $\mathcal{CB}(\mathcal{V})$  dual to  $\Psi_{d!}$ . On objects it is defined as  $\Psi_{d*}(A) := (\Psi_{d!}(A^*))^*$  and on morphisms as  $\Psi_{d*}(f) := (\Psi_{d!}(f^*))^*$ .

**Corollary 3.8.** *Let  $\mathcal{V}$  be a rigid braided monoidal category. Then, for any  $d \in \mathbb{N}$ , the functor  $\Psi_{d*}$  is right adjoint to  $\Theta_d$ .*

*Proof.* By the contravariance of  $(-)^*$  and Proposition 3.7 we have:

$$\begin{aligned}
\text{Hom}_{\mathcal{CB}(\mathcal{V})}(B, \Psi_{d*}(A)) &= \text{Hom}_{\mathcal{CB}(\mathcal{V})}(B, \Psi_{d!}(A^*)^*) = \text{Hom}_{\mathcal{CB}(\mathcal{V})}(\Psi_{d!}(A^*), B^*) \\
&= \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V})}(A^*, \Theta_d(B^*)) = \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V})}(\Theta_d(B^*)^*, A).
\end{aligned}$$

The statement follows from Remark 3.2. □

**3.5. The approximation functor.** Let  $d \in \mathbb{N}$ . In order to introduce the  $d$ -th approximation functor, we first analyze the components of the unit in the adjunction  $\Psi_{d!} \dashv \Theta_d$ . For  $A$  in  $\mathcal{CB}^{\leq d}(\mathcal{V})$  this is  $\Xi_{A, \Psi_{d!}}(A)(\text{id}_{\Psi_{d!}(A)}) = (\eta_A)_{\leq d}$ .

**Proposition 3.9.** *Let  $d \geq 0$ . For any object  $A$  in  $\mathcal{CB}^{\leq d}(\mathcal{V})$ , the morphism  $(\eta_A)_{\leq d}: A \rightarrow \Theta_d(\Psi_{d!}(A))$  is an isomorphism. Therefore  $\Theta_d$  is essentially surjective.*

*Proof.* We prove injectivity of the composition of the inclusion  $A \rightarrow T(A)$  with the canonical projection  $T(A) \rightarrow \Psi_{d!}(A)$ . The standard grading on  $T(A)$ , where  $T^l(A) = A^{\otimes l}$ , induces a filtration on  $T(A)$  and  $\Psi_{d!}(A)$ . For  $m \geq 0$ , let  $\Psi_{d!}^{\leq m}(A)$  be the  $m$ -th term in the filtration and let  $\text{gr}(\Psi_{d!}(A))$  be the associated graded algebra, with  $m$ -th component  $\text{gr}(\Psi_{d!}(A))_m = \Psi_{d!}^{\leq m}(A)/\Psi_{d!}^{\leq m-1}(A)$ . There is a natural graded algebra morphism  $\phi = \bigoplus_{m \geq 0} \phi_m$  where  $\phi_m: T^m(A) \rightarrow \text{gr}(\Psi_{d!}(A))_m$  is the composition of the projection onto  $\Psi_{d!}^{\leq m}(A)$  with the projection onto  $\text{gr}(\Psi_{d!}(A))_m$ . We have  $\text{gr}(\Psi_{d!}(A))_0 = \mathbb{k}$  and  $\text{gr}(\Psi_{d!}(A))_1 = \text{Ker}(\epsilon_A) = \bigoplus_{j > 0} A_j$ . Then  $\phi_0$  is the identity on  $\mathbb{k}$  and  $\phi_1$  is the projection  $T^1(A) = A \rightarrow \bigoplus_{j > 0} A_j$ , i.e., it maps  $a \in A$  to  $a - \epsilon_A(a)$ . Arguing as in [12, §17.3, Corollary A], we see that the restriction of  $\eta_A$  to  $\text{Ker}(\epsilon_A)$  is injective and that  $\text{Ker}(\epsilon_A)$  is a complement to  $\mathbb{k}$  in  $\Psi_{d!}(A)$ . Hence,  $\eta_A$  is injective.

Since  $(\eta_A)_{\leq d}: A \rightarrow \Theta_d(\Psi_{d!}(A))$  is an algebra morphism, to prove surjectivity it is enough to show that  $\Theta_d(\Psi_{d!}(A))$  is generated as an algebra by  $\eta_A(A)$ . This is the case because  $\Theta_d(\Psi_{d!}(A))$  is an algebra quotient of  $\Psi_{d!}(A)$ . □

Since  $(\eta_A)_{\leq d}$  is the identity in degree 1, and since  $k1_A$  is identified with  $\mathbf{1}_{\mathcal{V}} = k1_{\mathbb{k}}$  we can and will identify  $A$  with  $\Theta_d(\Psi_{d!}(A))$  and  $(\eta_A)_{\leq d}$  with the identity map.

We consider the endofunctor

$$F_d := \Psi_{d!} \circ \Theta_d: \mathcal{CB}(\mathcal{V}) \rightarrow \mathcal{CB}(\mathcal{V}),$$

which we call the  $d$ -th approximation functor, and the natural transformation

$$\pi^d: F_d \rightarrow \text{id}_{\mathcal{CB}(\mathcal{V})}$$

which is the counit of the adjunction  $\Psi_{d!} \dashv \Theta_d$ . Its component  $\pi_B^d$  at  $B$  in  $\mathcal{CB}(\mathcal{V})$  is  $\Gamma_{\Theta_d(B), \Psi_{d!}(\Theta_d(B))}(\text{id}_{\Theta_d(B)})$ .

**Lemma 3.10.** *We have the following properties:*

- (1) For any object  $B$  in  $\mathcal{CB}(\mathcal{V})$ , we have  $\Theta_d(F_d(B)) = \Theta_d(B)$ .
- (2) For any  $B$  in  $\mathcal{CB}(\mathcal{V})$ , the map  $\pi_B^d$  is the unique morphism from  $F_d B$  to  $B$  such that  $\Theta_d(\pi_B^d): \Theta_d(F_d(B)) = \Theta_d(B) \rightarrow \Theta_d(B)$  is the identity map.
- (3) For any  $B, C$  in  $\mathcal{CB}(\mathcal{V})$  and any morphism  $p: C \rightarrow B$  such that  $\Theta_d(p): \Theta_d C \rightarrow \Theta_d B$  is an isomorphism, there is a unique morphism  $\tilde{p}_B: F_d(B) \rightarrow C$  such that  $p \circ \tilde{p}_B = \pi_B^d$ .

*Proof.* (1) follows from Proposition 3.9 applied to  $A = \Theta_d(B)$ . By Proposition 3.9 we see that  $\pi_B^d = \Gamma_{\Theta_d(B), \Psi_{d!}(\Theta_d(B))}(\text{id}_{\Theta_d(B)})$  is the unique morphism  $\Psi_{d!}(\Theta_d(B)) \rightarrow B$  in  $\mathcal{CB}(\mathcal{V})$  extending the identity on  $B_{\leq d}$ , i.e., such that  $\Theta_d(\pi_B^d) = \text{id}_{\Theta_d(B)}$ , giving (2). We prove (3). Let  $\tilde{p}_B := \Gamma_{\Theta_d(B), C}(\Theta_d(p)^{-1})$ . By definition of  $\Gamma$  it is the unique morphism in  $\mathcal{CB}(\mathcal{V})$  extending  $\Theta_d(p)^{-1}$  to  $F_d(B)$ , so  $p \circ \tilde{p}_B$  satisfies (2), whence  $p \circ \tilde{p}_B = \pi_B^d$ . By construction  $\tilde{p}_B$  is unique with this property.  $\square$

The functor  $F_d$  generalizes the construction of the  $d$ -th approximation from bialgebras generated in degree 1 to all connected bialgebras:

**Theorem 3.11.** *Let  $d \geq 2$ . Then the restriction of the functor  $F_d$  to  $\mathcal{CB}^1(\mathcal{V})$  is naturally isomorphic to the  $d$ -atic covering functor (2.4).*

*Proof.* Let  $B = T_!(B_1)/J \in \mathcal{CB}^1(\mathcal{V})$  and let  $\widehat{B}_d = T_!(B_1)/(\bigoplus_{j \leq d} T_!^j(B_1) \cap J)$  be its  $d$ -th cover. Let  $\xi_B$  be the composition of the inclusions  $B_1 \subset B_{\leq d}$  and  $\widehat{B}_{\leq d} \subset T(\Theta_d(B))$  and let  $\zeta_B$  be the composition of  $\xi_B$  with the natural projection  $\pi_B: T(\Theta_d(B)) \rightarrow \Psi_{d!}(\Theta_d(B)) = F_d(B)$ . By the universal property of  $T_!(B_1)$ , there are unique morphisms  $\widehat{\xi}_B$  and  $\widehat{\zeta}_B$  in  $\mathcal{CB}(\mathcal{V})$  for which the diagram below is commutative.

$$\begin{array}{ccccc} B_1 & \xrightarrow{\xi_B} & T_!(\Theta_d(B)) & \xrightarrow{\pi_B} & F_d(B) \\ & \searrow & \widehat{\xi}_B \uparrow & \nearrow \widehat{\zeta}_B & \\ & & T_!(B_1) & & \end{array}$$

We show that  $\widehat{\zeta}_B$  factors through  $\widehat{B}_d$ . By definition of  $J_{\Theta_d(B)}$  and Proposition 3.9, and with the appropriate identifications, for  $j \leq d$  and  $b_1, \dots, b_j \in B_1$  there holds

$$\pi_B(b_1 \otimes \dots \otimes b_j) = \pi_B(m_{\Theta_d(B)}^{(j-1)}(b_1 \otimes \dots \otimes b_j)) = m_{\Theta_d(B)}^{(j-1)}(b_1 \otimes \dots \otimes b_j) = m_B^{(j-1)}(b_1 \otimes \dots \otimes b_j),$$

hence for any  $j \leq d$  and any  $b \in T_!^j(B_1) \cap J$  there holds  $\pi_B \widehat{\xi}_B(b) = \pi_B(m_B^{(j-1)}b) = 0$ , whence  $\pi_B \widehat{\xi}_B(\bigoplus_{j \leq d} T_!^j(B_1) \cap J) = 0$ . Therefore there is a unique morphism  $\overline{\zeta}_B: \widehat{B}_d \rightarrow F_d(B)$  in

$\mathcal{CB}(\mathcal{V})$  for which the diagram below is commutative

$$\begin{array}{ccccc}
B_1 & \xrightarrow{\xi_B} & T_!(\Theta_d(B)) & \xrightarrow{\pi_B} & F_d(B) \\
& \searrow & \uparrow \widehat{\xi}_B & \nearrow \widehat{\zeta}_B & \uparrow \overline{\zeta}_B \\
& & T_!(B_1) & \longrightarrow & \widehat{B}_d
\end{array}$$

In this way we have constructed a natural morphism of functors  $\overline{\zeta}: (\widehat{\phantom{B}})_d \rightarrow F_d$ .

Now, as an algebra  $\Theta_d(B)$  is a quotient of  $B$ , hence it is generated by  $B_1$ . Therefore  $F_d(B)$  is generated by  $\widehat{\zeta}_B(B_1)$ , and so  $\widehat{\zeta}_B$  is surjective, whence  $\overline{\zeta}_B$  is surjective. We prove injectivity. Observe that

$$\begin{aligned}
\Theta_d(\widehat{B}_d) &= (T_!(B_1)/(\bigoplus_{j \leq d} T_!^j(B_1) \cap J))/(\bigoplus_{l > d} \widehat{B}_d)_l = T_!(B_1)/(\bigoplus_{j > d} T_!^j(B_1) \oplus (\bigoplus_{j \leq d} T_!^j(B_1) \cap J)), \\
\Theta_d(B) &= (T_!(B_1)/J)/\bigoplus_{l > d} B_l = T_!(B_1)/(\bigoplus_{j > d} T_!^j(B_1) + J),
\end{aligned}$$

respectively. Since  $(\bigoplus_{j \leq d} T_!^j(B_1) \cap J) + T_!^{\geq d}(B_1) = J + T_!^{\geq d}(B_1)$ , the two algebras coincide. Let  $p_B: \widehat{B}_d \rightarrow B$  be the natural projection. Then, the map  $\Theta_d(p_B)$  is the identity, because it is induced from the identity on  $B_1$ . Let  $\tilde{p}_B: F_d B \rightarrow \widehat{B}_d$  be the morphism in  $\mathcal{CB}(\mathcal{V})$  whose existence is guaranteed by Lemma 3.10 (3). Then  $\tilde{p}_B \circ \overline{\zeta}_B \in \text{Hom}_{\mathcal{CB}(\mathcal{V})}(F_d B, \widehat{B}_d)$  and it corresponds to the identity in  $\text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V})}(\Theta_d(B), \Theta_d(B))$  through (3.7). By Proposition 3.7, we have  $\tilde{p}_B \circ \overline{\zeta}_B = \text{id}_{F_d B}$ . So,  $\overline{\zeta}_B$  is injective and  $\overline{\zeta}$  is a natural isomorphism of functors.  $\square$

- Example 3.4.** (1) If  $V$  is an object in  $\mathcal{V}$  concentrated in degree 1 then the  $d$ -th approximation of  $T_!(V)$  is  $T_!(V)$  for any  $d \geq 1$ .
- (2) In the category of vector spaces with usual flip operator, if  $V$  has basis  $\{v_1, \dots, v_n\}$ , then  $F_2(T_*(V))$  is generated as an algebra by the variables  $x_i, x_{ij}$  for  $i, j \in \{1, \dots, n\}$  with relations  $x_{ij}x_{kl} = x_{ij}x_l = x_lx_{ij} = x_ix_j - x_{ij} - x_{ji} = 0$  for  $i, j, k, l \in \{1, \dots, n\}$ . The coproduct is determined by  $\Delta(x_i) = 1 \otimes x_i + x_i \otimes 1$  and  $\Delta(x_{ij}) = 1 \otimes x_{ij} + x_i \otimes x_j + x_{ij} \otimes 1$ .
- (3) The 0-th approximation of any  $A \in \mathcal{CB}(\mathcal{V})$  is  $\mathbf{1}_{\mathcal{V}}$ .
- (4) The first approximation of  $A \in \mathcal{CB}(\mathcal{V})$  is  $F_1(A) = T_!(A_1)$ .

Note that  $A$  is finitely presented if and only if  $A = F_d(A)$  for some  $d$  with  $\dim A_{\leq d} < \infty$ . Indeed, the condition  $A = F_d(A)$  implies that the relations are generated up to degree  $d$ , while the condition  $\dim A_{\leq d} < \infty$  implies that one can choose finitely many generators.

## 4. SOME EQUIVALENCES OF CATEGORIES

**4.1. Inverse limits of categories.** We call a projective system of categories indexed by  $\mathbb{N}$  a pair  $((\mathcal{C}_d)_{d \in \mathbb{N}}, (\pi_{de})_{d \leq e})$  where  $(\mathcal{C}_d)_{d \in \mathbb{N}}$  is a collection of categories indexed by  $\mathbb{N}$ , and  $\pi_{de}: \mathcal{C}_e \rightarrow \mathcal{C}_d$  for  $d \leq e$  are functors satisfying  $\pi_{de} \circ \pi_{ef} = \pi_{df}$  if  $d \leq e \leq f$  and  $\pi_{dd} = \text{id}$  for all  $d \in \mathbb{N}$ .

In the spirit of [22, §5.1], we define the inverse limit category  $\varprojlim_{d \in \mathbb{N}} \mathcal{C}_d$ , as the category whose objects are pairs  $((E_d)_{d \in \mathbb{N}}, (\phi_{de})_{d \leq e})$ , where each  $E_d$  is an object in  $\mathcal{C}_d$ , and each  $\phi_{de}$  is an isomorphism  $\phi_{de}: \pi_{de}(E_e) \rightarrow E_d$  in  $\mathcal{C}_d$ , satisfying the compatibility condition  $\phi_{de} \circ \pi_{de}(\phi_{ef}) =$

$\phi_{df}$  for  $d \leq e \leq f$ . In particular,  $\phi_{ee} \circ \phi_{ee} = \phi_{ee}$ . Hence, in the categories we will be interested in, the maps  $\phi_{ee}$  will be the identity. Morphisms from  $((E_d)_{d \in \mathbb{N}}, (\phi_{de})_{d \leq e})$  to  $((E'_d)_{d \in \mathbb{N}}, (\phi'_{de})_{d \leq e})$  are defined as families of morphisms  $\psi_d: E_d \rightarrow E'_d$  in  $\mathcal{C}_d$  for each  $d \in \mathbb{N}$  such that the diagram below commutes for each  $d \leq e$ :

$$\begin{array}{ccc} \pi_{de}(E_e) & \xrightarrow{\phi_{de}} & E_d \\ \pi_{de}(\psi_e) \downarrow & & \downarrow \psi_d \\ \pi_{de}(E'_e) & \xrightarrow{\phi'_{de}} & E'_d \end{array} \quad (4.9)$$

where the vertical arrow on the left is obtained by applying the functor  $\pi_{de}$  to the morphism  $\psi_e: E_e \rightarrow E'_e$ . This construction is a special case of the quasi-limit, [9, p. 217].

The truncation  $\bigoplus_{j \leq d} A_j \mapsto \bigoplus_{j \leq c} A_j$  induces a family of functors  $(\ )_{\leq c, d}: \mathcal{CB}^{\leq d}(\mathcal{V}) \rightarrow \mathcal{CB}^{\leq c}(\mathcal{V})$  for  $c \leq d$ , and  $((\mathcal{CB}^{\leq d}(\mathcal{V}))_{d \in \mathbb{N}}, (\ )_{\leq c, d})_{c \leq d}$  is a projective system of categories. Observe that  $(\ )_{\leq c, d} \Theta_d = \Theta_c$  for any  $c \leq d$ .

**Proposition 4.1.** *The inverse limit category  $\varprojlim_{d \in \mathbb{N}} \mathcal{CB}^{\leq d}(\mathcal{V})$  is equivalent to  $\mathcal{CB}(\mathcal{V})$ .*

*Proof.* We define a functor  $\Theta: \mathcal{CB}(\mathcal{V}) \rightarrow \varprojlim_{d \in \mathbb{N}} \mathcal{CB}^{\leq d}(\mathcal{V})$  as follows. For an object  $A$  in  $\mathcal{CB}(\mathcal{V})$  we set  $\Theta(A) := ((\Theta_d(A))_{d \geq 0}, \text{id}_{c \leq d})$  where  $\text{id}_{c \leq d}$  denotes the identity morphism in  $\mathcal{CB}^{\leq c}(\mathcal{V})$ . For a morphism  $f: A \rightarrow B$  in  $\mathcal{CB}(\mathcal{V})$ , we set  $\Theta(f) := (\Theta_d(f))_{d \in \mathbb{N}}: \Theta(A) \rightarrow \Theta(B)$ . By construction the functor  $\Theta$  is fully faithful.

We show that  $\Theta$  is essentially surjective. Let  $((E^d)_{d \geq 0}, (\phi_{cd})_{c \leq d})$  be an object in  $\varprojlim_{d \in \mathbb{N}} \mathcal{CB}_{\leq d}(\mathcal{V})$ , with  $E^d = \bigoplus_{i=0}^d E_i$ . We define the object  $\tilde{E}$  of  $\mathcal{V}_{gr}$  as follows:  $\tilde{E} = \bigoplus_{d \geq 0} E_d$ . Then  $\tilde{E}_0 = E_0^0 = \mathbf{1}_{\mathcal{V}}$ . The morphisms

$$m_{i,j} := m_{E^{i+j}} \circ (\phi_{i,i+j}^{-1} \otimes \phi_{j,i+j}^{-1}): \tilde{E}_i \otimes \tilde{E}_j = E_i^i \otimes E_j^j \rightarrow E_{i+j}^{i+j} = \tilde{E}_{i+j}$$

combine to a graded, associative multiplication morphism on  $\tilde{E}$ . Similarly, the maps

$$\tilde{\Delta}_d := \bigoplus_{i+j=d} (\phi_{i,d} \otimes \phi_{j,d}) \Delta_d: \tilde{E}_d = E_d^d \rightarrow \bigoplus_{i+j=d} E_i^i \otimes E_j^j = \bigoplus_{i+j=d} \tilde{E}_i \otimes \tilde{E}_j$$

combine to a graded, coassociative comultiplication morphism on  $\tilde{E}$ . The counit is given by taking the counit on each  $E_d^d$ . A tedious computation shows that  $\tilde{E}$  is an object in  $\mathcal{CB}(\mathcal{V})$  and that the sequence of bialgebra morphisms  $f^d: \tilde{E}_{\leq d} \rightarrow E^d$  given by  $f^d := \bigoplus_{i \leq d} f_i^d = \bigoplus_{l \leq d} \phi_{ld}^{-1}|_{E_l^d}$  combine to give an isomorphism  $\Theta(\tilde{E}) \rightarrow ((E^d)_{d \geq 0}, (\phi_{cd})_{c \leq d})$ .  $\square$

**4.2. An alternative category of truncated bialgebras.** We describe here an alternative approach to the truncated versions of  $\mathcal{CB}(\mathcal{V})$ . Let  $d$  be a non-negative integer. The  $d$ -th truncated category  $\mathcal{V}_{\leq d}$  of  $\mathcal{V}_{gr}$  is the category with the same objects as  $\mathcal{V}_{gr}$  and morphisms  $f = (f_j)_{0 \leq j \leq d}$ , i.e., only in degrees less than or equal to  $d$ .

In other words, we disregard graded components corresponding to terms greater than  $d$ . In the language of [6, 2.2], the category  $\mathcal{V}_{\leq d}$  is the braided monoidal category obtained from  $\mathcal{V}_{gr}$  by taking the quotient with respect to the tensor ideal consisting of graded morphisms that are 0 up to degree  $d$ . The unit in  $\mathcal{V}_{\leq d}$  is the same as in  $\mathcal{V}_{gr}$ . The braiding in  $\mathcal{V}_{\leq d}$  is

given by  $\varphi_{A,B} = (\bigoplus_{i+j=k} c_{A_i,B_j})_{0 \leq k \leq d}$ , where  $c_{A_i,B_j}$  is the braiding in  $\mathcal{V}$ . Note that  $\mathcal{V}_{\leq 0} = \mathcal{V}$  with the usual unit and braiding.

If  $\mathcal{V}$  is rigid, then each category  $\mathcal{V}_{\leq d}$  is rigid, by taking graded duals. By the discussion in Section 2.2, the category  $\mathcal{CB}(\mathcal{V}_{\leq d})$  of connected bialgebras in  $\mathcal{V}_{\leq d}$  has then a duality.

**Proposition 4.2.** *Let  $d \in \mathbb{N}$ . The identity functor on  $\mathcal{V}_{gr}$  induces an equivalence of categories  $\mathcal{R}_d: \mathcal{CB}^{\leq d}(\mathcal{V}) \rightarrow \mathcal{CB}(\mathcal{V}_{\leq d})$ . If  $\mathcal{V}$  is rigid,  $\mathcal{R}_d$  is compatible with duality.*

*Proof.* An object  $A$  in  $\mathcal{CB}^{\leq d}(\mathcal{V})$  is an object in  $\mathcal{V}_{gr}$ , hence an object in  $\mathcal{V}_{\leq d}$ , and  $A_0 = \mathbf{1}_{\mathcal{V}} = \mathbf{1}_{\mathcal{V}_{\leq d}}$ . The multiplication  $m_A$ , the comultiplication  $\Delta_A$  and the counit  $\epsilon_A$  of  $A$  are morphisms in  $\mathcal{V}_{\leq d}$  with which  $A$  becomes a graded algebra and coalgebra in  $\mathcal{V}_{\leq d}$ . Finally, (3.5) implies that  $A$  is a connected bialgebra in  $\mathcal{V}_{\leq d}$ . Morphisms in  $\mathcal{CB}^{\leq d}(\mathcal{V})$  are graded algebra and coalgebra morphisms in  $\mathcal{V}_{\leq d}$ , hence the identity functor induces a fully faithful functor  $\mathcal{CB}^{\leq d}(\mathcal{V}) \rightarrow \mathcal{CB}(\mathcal{V}_{\leq d})$ . Note that any algebra  $A$  in  $\mathcal{V}_{\leq d}$  is isomorphic to its truncation  $A_{\leq d}$ , hence the functor is essentially surjective. The statement about duality follows because duality in  $\mathcal{V}_{gr}$  and  $\mathcal{V}_{\leq d}$  coincides on objects and morphisms up to degree  $d$ .  $\square$

For  $c \leq d$ , let  $\pi_{cd}: \mathcal{V}_{\leq d} \rightarrow \mathcal{V}_{\leq c}$  be the functors given by the identity on objects and on morphisms by disregarding the components greater than  $c$ . Then  $((\mathcal{V}_{\leq d})_{d \in \mathbb{N}}, (\pi_{cd})_{c \leq d})$  is a projective system of categories whose limit  $\varprojlim_{d \in \mathbb{N}} \mathcal{V}_{\leq d}$  is equivalent to  $\mathcal{V}_{gr}$ . By construction, for the restriction of  $\pi_{cd}$  to  $\mathcal{CB}(\mathcal{V}_{\leq d})$  there holds  $\mathcal{R}_c(\cdot)_{\leq c,d} = \pi_{cd} \mathcal{R}_d$ . Then, by Proposition 4.1 the inverse limit of the projective system  $((\mathcal{CB}^{\leq d}(\mathcal{V}))_{d \geq 1}, (\pi^{cd})_{c \leq d})$  is  $\mathcal{CB}(\mathcal{V})$ .

## 5. COMPATIBILITY WITH EQUIVALENCES

In this section, we show that the  $d$ -th approximation functors behave well with respect to equivalence of braided categories and we apply it to the equivalence between categories of Yetter-Drinfeld modules of Hopf algebras related by a cocycle-twist, [2, 15].

**Theorem 5.1.** *Let  $(\mathcal{T}, \omega)$  be an equivalence of braided categories from  $\mathcal{V}$  to  $\mathcal{V}'$  with quasi-inverse  $(\mathcal{S}, \alpha)$ . Let  $\Upsilon$  be a natural isomorphism from  $\mathcal{S} \circ \mathcal{T}$  to the identity functor  $\text{id}_{\mathcal{V}}$ . For  $d \in \mathbb{N}$ , let  $\mathcal{T}: \mathcal{CB}(\mathcal{V}) \rightarrow \mathcal{CB}(\mathcal{V}')$ , and  $\mathcal{T}^d: \mathcal{CB}^{\leq d}(\mathcal{V}) \rightarrow \mathcal{CB}^{\leq d}(\mathcal{V}')$ ,  $\mathcal{S}: \mathcal{CB}(\mathcal{V}') \rightarrow \mathcal{CB}(\mathcal{V})$  and  $\mathcal{S}^d: \mathcal{CB}^{\leq d}(\mathcal{V}') \rightarrow \mathcal{CB}^{\leq d}(\mathcal{V})$  be the induced functors. Let  $\Theta_d: \mathcal{CB}(\mathcal{V}) \rightarrow \mathcal{CB}^{\leq d}(\mathcal{V})$ ,  $\Theta'_d: \mathcal{CB}(\mathcal{V}') \rightarrow \mathcal{CB}^{\leq d}(\mathcal{V}')$ ,  $\Psi_{d!}: \mathcal{CB}^{\leq d}(\mathcal{V}) \rightarrow \mathcal{CB}(\mathcal{V})$ ,  $\Psi'_{d!}: \mathcal{CB}^{\leq d}(\mathcal{V}') \rightarrow \mathcal{CB}(\mathcal{V}')$ ,  $F_d: \mathcal{CB}(\mathcal{V}) \rightarrow \mathcal{CB}(\mathcal{V})$  and  $F'_d: \mathcal{CB}(\mathcal{V}') \rightarrow \mathcal{CB}(\mathcal{V}')$  denote the  $d$ -th truncation,  $d$ -th extension and  $d$ -th approximation functors in  $\mathcal{V}$  and  $\mathcal{V}'$ , respectively. Then*

- (1)  $\bigoplus_{i=0}^d \Upsilon$  is a natural isomorphism from  $\mathcal{S}^d \circ \Theta'_d \circ \mathcal{T}$  to  $\Theta_d$ ;
- (2)  $\Psi_{d!}$  is naturally isomorphic to  $\mathcal{S} \circ \Psi'_{d!} \circ \mathcal{T}^d$ ;
- (3)  $F_d$  is naturally isomorphic to  $\mathcal{S} \circ F'_d \circ \mathcal{T}$ .
- (4) For  $A$  in  $\mathcal{CB}(\mathcal{V})$ , we have  $A \simeq F_d(A)$  if and only if  $\mathcal{T}(A) \simeq F'_d \mathcal{T}(A)$ .
- (5) If  $\mathcal{T} \circ \mathcal{S} = \text{id}_{\mathcal{V}'}$  and  $\mathcal{S} \circ \mathcal{T} = \text{id}_{\mathcal{V}}$ , that is, if  $\mathcal{V}$  and  $\mathcal{V}'$  are isomorphic, then we have uniquely determined identifications

$$\Theta_d = \mathcal{S}^d \circ \Theta'_d \circ \mathcal{T}, \quad \Psi_{d!} = \mathcal{S} \circ \Psi'_{d!} \circ \mathcal{T}^d, \quad F_d = \mathcal{S} \circ F'_d \circ \mathcal{T}. \quad (5.10)$$

*Proof.* (1) Let  $A = \bigoplus_{i \geq 0} A_i$  be an object in  $\mathcal{CB}(\mathcal{V})$ . Then  $\mathcal{T}(A) = \bigoplus_{i \geq 0} \mathcal{T}(A_i)$ . Hence  $\Theta'_d(\mathcal{T}(A)) = \bigoplus_{i=0}^d \mathcal{T}(A_i)$  as coalgebras. Therefore  $\mathcal{S}^d(\Theta'_d(\mathcal{T}(A))) = \bigoplus_{i=0}^d \mathcal{S}(\mathcal{T}(A_i)) \simeq \bigoplus_{i=0}^d A_i$ , where the last isomorphism is  $\bigoplus_{i=0}^d \Upsilon_{A_i}$ . Now,  $\mathcal{T}(\bigoplus_{j>d} A_j) = \bigoplus_{j>d} \mathcal{T}(A)_j$ , so

$\Theta'_d(\mathcal{T}(A)) = \mathcal{T}(A) / \bigoplus_{j>d} \mathcal{T}(A_j)$  as algebras. Hence  $\bigoplus_{i=0}^d \Upsilon_{A_i}$  induces an algebra isomorphism  $\mathcal{S}^d(\Theta'_d(\mathcal{T}(A))) = \mathcal{S}(\mathcal{T}(A)) / (\bigoplus_{j>d} \mathcal{S}(\mathcal{T}(A))) \simeq \Theta_d(A)$ . Since  $\Upsilon$  is a natural isomorphism, then  $\bigoplus_{i=0}^d \Upsilon$  is a natural isomorphism from  $\mathcal{S}^d \circ \Theta'_d \circ \mathcal{T}$  to  $\Theta_d$ .

(2) For  $A \in \mathcal{CB}^{\leq d}(\mathcal{V})$  and  $B \in \mathcal{CB}(\mathcal{V})$  we have the sequence of natural isomorphisms

$$\begin{aligned} \text{Hom}_{\mathcal{CB}(\mathcal{V})}(\mathcal{S} \circ \Psi'_{d!} \circ \mathcal{T}^d A, B) &\simeq \text{Hom}_{\mathcal{CB}(\mathcal{V})}(\mathcal{S} \circ \Psi'_{d!} \circ \mathcal{T}^d A, \mathcal{S} \circ \mathcal{T}B) \\ &\simeq \text{Hom}_{\mathcal{CB}(\mathcal{V}')}(\Psi'_{d!} \mathcal{T}^d A, \mathcal{T}B) \simeq \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V}')}(\mathcal{T}^d A, \Theta'_d \mathcal{T}B) \\ &\simeq \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V}')}(\mathcal{T}^d A, \mathcal{T}^d \circ \mathcal{S}^d \circ \Theta'_d \mathcal{T}B) \simeq \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V}')}(\mathcal{T}^d A, \mathcal{T}^d \Theta_d B) \\ &\simeq \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V}')}(\mathcal{T}^d A, \Theta_d B) \end{aligned} \quad (5.11)$$

where in the second isomorphism we use that  $\mathcal{S}$  is fully faithful, in the third the adjunction  $\Psi'_{d!} \dashv \Theta'_d$ , in the fourth that  $\mathcal{T}^d$  is the quasi inverse of  $\mathcal{S}^d$ , in the fifth we compose with  $\mathcal{T}^d(\bigoplus_{i=0}^d \Upsilon_{B_i})$  and in the last we use that  $\mathcal{T}^d$  is fully faithful. Hence  $\mathcal{S} \circ \Psi'_{d!} \circ \mathcal{T}^d$  is left adjoint to  $\Theta_d$ , and so it is naturally isomorphic to  $\Psi_{d!}$  by [14, Corollary 1].

(3) Follows from (1) and (2) and (4) follows from (3). Finally, observe that if  $\mathcal{T}$  and  $\mathcal{S}$  are mutual inverses, we may choose  $\Upsilon$  to be the identity, so  $\Theta_d = \mathcal{S}^d \circ \Theta'_d \circ \mathcal{T}$ . In this case, for  $A \in \mathcal{CB}^{\leq d}(\mathcal{V})$ , the natural isomorphism  $\Psi'_{d!} \mathcal{T}^d(A) \rightarrow \mathcal{T} \Psi_{d!}(A)$  is the unique morphism corresponding to  $\text{id}_A$  through the chain of identifications

$$\begin{aligned} \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V})}(A, A) &\equiv \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V}')}(\mathcal{T}^d(A), \mathcal{T}^d \Theta_d \Psi_{d!}(A)) \\ &\equiv \text{Hom}_{\mathcal{CB}^{\leq d}(\mathcal{V}')}(\mathcal{T}^d(A), \Theta'_d \mathcal{T} \Psi_{d!}(A)) \simeq \text{Hom}_{\mathcal{CB}(\mathcal{V}')}(\Psi'_{d!} \mathcal{T}^d(A), \mathcal{T} \Psi_{d!}(A)), \end{aligned}$$

where the last isomorphism is given by (3.7). In other words, it is the unique morphism extending the identity, up to identifications.

The last equality immediately follows.  $\square$

**5.1. Cocycle twisting.** Let  $H$  be a Hopf algebra with multiplication  $m_H$ , comultiplication  $\Delta$  and counit  $\epsilon$ . We adopt a Sweedler's like notation for coproducts and coactions, omitting the summation symbol. We recall that a convolution invertible linear map  $\sigma : H \otimes H \rightarrow \mathbb{k}$  is called a normalized 2-cocycle for  $H$  if

$$\sigma(x_1 \otimes y_1) \sigma(m_H(x_2 \otimes y_2) \otimes z) = \sigma(y_1 \otimes z_1) \sigma(x \otimes m_H(y_2 \otimes z_2)), \quad \forall x, y, z \in H, \quad \sigma(1 \otimes 1) = 1. \quad (5.12)$$

If  $H = \mathbb{k}G$  is the group algebra of a finite group  $G$ , then a 2-cocycle is the linear extension of a usual 2-cocycle on  $G$ :

$$\sigma(x, y) \sigma(xy, z) = \sigma(y, z) \sigma(x, yz), \quad \sigma(x, 1_G) = \sigma(1_G, x) = 1, \quad \forall x, y, z \in G. \quad (5.13)$$

The set of normalized 2-cocycles on  $H$  with values in  $\mathbb{k}$  is denoted by  $Z^2(H, \mathbb{k})$ .

We recall from [7, Theorem 1.6] that the twist of  $H$  by a 2-cocycle  $\sigma$  is the Hopf algebra  $H_\sigma$  with same underlying vector space and coproduct as  $H$ , and multiplication given by

$$m_{H_\sigma}(x \otimes y) := \sigma(x_1 \otimes y_1) m_H(x_2 \otimes y_2) \sigma^{-1}(x_3 \otimes y_3), \quad x, y \in H,$$

where  $\sigma^{-1}$  denotes the convolution inverse of  $\sigma$ .

According to [15, Theorem 2.7] there is a braided monoidal equivalence  $(\mathcal{T}_\sigma, \omega)$  between the categories of Yetter-Drinfeld modules  ${}^H_H \mathcal{YD}$  to  ${}^{H_\sigma}_{H_\sigma} \mathcal{YD}$ . For an object  $V$  in  ${}^H_H \mathcal{YD}$  with  $H$ -action  $\triangleright$  and coaction  $\lambda : V \rightarrow H \otimes V$  mapping  $v \in V$  to  $v_{-1} \otimes v_0$ , the object  $\mathcal{T}_\sigma(V)$  has underlying vector space  $V$ , coaction  $\lambda$ , and  $H_\sigma$ -action given by  $h \triangleright_\sigma v := \sigma(h_1 \otimes v_{-1})(h_2 \triangleright$

$v_0)_0\sigma^{-1}((h_2 \triangleright v_0)_{-1} \otimes h_3)$ , for  $h \in H$  and  $v \in V$ . At the level of morphisms  $\mathcal{T}_\sigma$  is the identity. The components of the natural transformation  $\omega$  are given by

$$\begin{aligned} \omega_{V,W}: V_\sigma \otimes W_\sigma &\rightarrow (V \otimes W)_\sigma \\ (v \otimes w) &\mapsto \sigma(v_{-1} \otimes w_{-1})v_0 \otimes w_0, \end{aligned}$$

for all  $v, w \in {}^H_H\mathcal{YD}$ .

Then,  $(\mathcal{T}_\sigma, J)$  induces a functor  $\mathcal{T}_\sigma: \mathcal{CB}({}^H_H\mathcal{YD}) \rightarrow \mathcal{CB}({}^{H_\sigma}_{H_\sigma}\mathcal{YD})$ . According to Remark 2.2, for  $A \in \mathcal{CB}({}^H_H\mathcal{YD})$  with multiplication  $m_A$ , the multiplication in  $\mathcal{T}_\sigma(A)$  is given by  $a \otimes a' \mapsto \sigma(a_{-1} \otimes a'_{-1})m_A(a_0 \otimes a'_0)$ , i.e., it is the algebra twisted by  $\sigma$ .

**Theorem 5.2.** *Let  $d \in \mathbb{N}$ . Let  $H$  be a Hopf algebra,  $\sigma \in Z^2(H, \mathbb{k})$ , and  $F_d, F'_d$  be the  $d$ -th approximation functors on  $\mathcal{CB}({}^H_H\mathcal{YD})$  and  $\mathcal{CB}({}^{H_\sigma}_{H_\sigma}\mathcal{YD})$ , respectively. Then*

- (1)  $F'_d \circ \mathcal{T}_\sigma = \mathcal{T}_\sigma \circ F_d$ .
- (2) For  $A \in \mathcal{CB}({}^H_H\mathcal{YD})$  there holds  $A \simeq F_d(A)$  if and only if  $F'_d(\mathcal{T}_\sigma(A)) \simeq \mathcal{T}_\sigma(A)$ .

*Proof.* If  $\sigma$  lies in  $Z^2(H, \mathbb{k})$ , then  $\sigma^{-1}$  lies in  $Z^2(H_\sigma, \mathbb{k})$ , [10, Remark 2.8.3] and  $(H_\sigma)_{\sigma^{-1}} = H$ . Hence  $\mathcal{T}_\sigma$  and  $\mathcal{T}_{\sigma^{-1}}$  are mutual inverses, see also [2, §3.4]. We conclude applying Theorem 5.1 (4) and (5).  $\square$

**5.2. A concrete example: Nichols algebras and cocycle twist on racks.** We discuss here the very concrete case of Nichols algebras corresponding to twist equivalent rack cocycles. We introduce the necessary terminology.

**Definition 5.1.** A rack is a pair  $(X, \triangleright)$  where  $X$  is a non-empty set and  $\triangleright$  is a binary operation on  $X$  satisfying the following conditions:

- (1) The map  $x \triangleright -: X \rightarrow X$  is bijective for any  $x \in X$ ;
- (2)  $x \triangleright (y \triangleright z) = (x \triangleright y) \triangleright (x \triangleright z)$  for any  $x, y, z \in X$ .

The prototypical example of a rack is a union of conjugacy classes in a finite group together with the conjugation operation.

**Definition 5.2.** A 2-cocycle of degree  $n$  on a rack  $(X, \triangleright)$  is a map  $q: X \times X \rightarrow \text{GL}_n(\mathbb{k})$  satisfying

$$q(x, y \triangleright z)q(y, z) = q(x \triangleright y, x \triangleright z)q(x, z) \quad (5.14)$$

for  $x, y, z \in X$ .

For a rack  $(X, \triangleright)$  and a 2-cocycle  $q$  of degree  $n$  on  $(X, \triangleright)$ , let  $\mathbb{k}X$  denote the formal linear span of elements in  $X$ . Then

$$c_q: (\mathbb{k}X \otimes \mathbb{k}^n) \otimes (\mathbb{k}X \otimes \mathbb{k}^n) \rightarrow (\mathbb{k}X \otimes \mathbb{k}^n) \otimes (\mathbb{k}X \otimes \mathbb{k}^n) \quad (5.15)$$

$$(x \otimes v) \otimes (y \otimes w) \mapsto (x \triangleright y \otimes q(x, y)(w)) \otimes (x \otimes v) \quad (5.16)$$

is a solution of the braid equation (2.3) for  $A = B = C = \mathbb{k}X$ . We can view  $\mathbb{k}X$  as an object in the additive  $\mathbb{k}$ -linear braided monoidal category  $\mathcal{V}$  generated by  $\mathbb{k}X$  and  $c_q$ . Conversely, every solution of (2.3) stemming from a finite-dimensional Yetter-Drinfeld module over a finite group can be constructed from a rack and a cocycle, [3, Thm 1.14].

We recall the construction of the Nichols algebra from Example 2.1 in this setup, which is valid for any vector space  $V$  equipped with a solution  $c = c_{V,V}$  of (2.3). For  $n \geq 2$ , we denote

the symmetric group on  $n$  letters by  $\mathbb{S}_n$  and chose  $s_i := (i \ i + 1) \in \mathbb{S}_n$  for  $i = 1, \dots, n - 1$  as a set of Coxeter generators. Let  $B_n$  be the braid group with presentation:

$$\langle \sigma_1, \dots, \sigma_{n-1} \mid \sigma_i \sigma_{i+1} \sigma_i = \sigma_{i+1} \sigma_i \sigma_{i+1}, \sigma_i \sigma_j = \sigma_j \sigma_i, \text{ if } |i - j| > 1 \rangle.$$

The Matsumoto section is the map  $M_n: \mathbb{S}_n \rightarrow B_n$  determined uniquely by the condition  $M_n(s_{i_1} \cdots s_{i_l}) = \sigma_{i_1} \cdots \sigma_{i_l}$  for any reduced expression  $s_{i_1} \cdots s_{i_l}$ .

For  $n \geq 2$  the action of the braid group  $B_n$  associated with  $V$  and  $c$  is the representation  $\rho_n: B_n \rightarrow \text{GL}(V^{\otimes n})$  obtained by letting  $\sigma_i$  act as  $c$  on the  $i$ -th and  $(i + 1)$ -th tensor factors and trivially on the others. The  $n$ -th quantum symmetrizer  $Q_n$  is then defined as the endomorphism  $\sum_{\sigma \in \mathbb{S}_n} \rho_n(M_n(\sigma))$  of  $V^{\otimes n}$ .

The Nichols algebra  $\mathcal{B}(V, c)$  is the graded algebra  $T(V) / \bigoplus_{n \geq 2} \ker(Q_n)$  with coproduct determined by requiring the elements in  $V$  to be primitive.

Let  $(C, \triangleright)$  be a rack given by a union of conjugacy classes in a finite group  $G$ . Let  $q, q'$  be 2-cocycles of degree 1 on  $(C, \triangleright)$ . Then  $q, q'$  are said to be twist-equivalent if there exists a 2-cocycle  $\sigma$  on  $G \times G$  satisfying

$$q'(x, y) = \sigma(x, y)q(x, y)\sigma(x \triangleright y, x)^{-1}, \quad \text{for all } x, y \in C. \quad (5.17)$$

**Corollary 5.3.** *Let  $\mathbb{k}X$  be a Yetter-Drinfeld module of a finite group  $G$ , supported by a conjugacy class and let  $q$  be the corresponding cocycle. Let  $q'$  be a twist-equivalent cocycle on  $X$ , and let  $\mathcal{B}(X, q)$  and  $\mathcal{B}(X, q')$  be the Nichols algebras associated with  $(\mathbb{k}X, c_q)$  and  $(\mathbb{k}X, c_{q'})$ , respectively. Then, for  $d \in \mathbb{N}$  there holds  $\mathcal{B}(X, q) \simeq \widehat{\mathcal{B}(X, q)}_d$  if and only if  $\mathcal{B}(X, q') \simeq \widehat{\mathcal{B}(X, q')}_d$ .*

*Proof.* Let  $\sigma \in Z^2(\mathbb{k}G, \mathbb{k}^\times)$  satisfy (5.17) for  $q$  and  $q'$ . It induces an equivalence of categories from  ${}_{\mathbb{k}G}^{\mathbb{k}G}\mathcal{YD}$  to  ${}_{\mathbb{k}G\sigma}^{\mathbb{k}G}\mathcal{YD}$ . According to [2, Lemma 3.9], the vector space  $\mathbb{k}X$  with braiding  $c_{q'}$  is the image through  $\mathcal{T}_\sigma$  of  $\mathbb{k}X$ . The statement follows from Theorems 3.11 and 5.2 and functoriality of the Nichols algebra.  $\square$

In order to introduce the definition of Nichols algebra associated with a braided vector space we need to recall some basic notions.

## APPENDIX A. AN ALTERNATIVE PROOF OF COROLLARY 5.3

In this appendix we present an alternative proof of Corollary 5.3. As a stepping stone, we prove the following proposition which is a direct consequence of the arguments in [15, Theorem 2.7] and [2, Theorem 3.8]. We spell out a direct proof that does not require any categorical language.

**Proposition A.1.** *Let  $X$  be a union of conjugacy classes in a finite group  $G$ . If  $q$  and  $q'$  are twist-equivalent cocycles on  $X$  with values in  $\mathbb{k}^\times$ , then for any  $n \geq 2$  the  $B_n$ -representations associated respectively with  $(\mathbb{k}X, c_{q'})$  and  $(\mathbb{k}X, c_q)$ , are isomorphic.*

*Proof.* Let  $\sigma \in Z^2(G, \mathbb{k}^\times)$  satisfy (5.17) for  $q$  and  $q'$ . For  $n \geq 2$ , let  $\rho'_n$  and  $\rho_n$  be the  $B_n$ -representations associated with  $(\mathbb{k}X, c_{q'})$  and  $(\mathbb{k}X, c_q)$ , respectively. We define the linear

isomorphism

$$f: (\mathbb{k}X)^{\otimes n} \rightarrow (\mathbb{k}X)^{\otimes n}$$

$$x_1 \otimes \cdots \otimes x_n \mapsto \left( \prod_{i=1}^{n-1} \sigma(x_i, x_{i+1} \cdots x_n) \right) x_1 \otimes \cdots \otimes x_n$$

for  $x_i \in X$  with  $i = 1, \dots, n$  and we show that  $\rho_n(\sigma_j)f = f(\rho'_n(\sigma_j))$  for any generator  $\sigma_j \in B_n$ . Let  $x_1, \dots, x_n \in X$ . We set  $\underline{x} = x_1 \otimes \cdots \otimes x_{j-1} \otimes (x_j \triangleright x_{j+1}) \otimes x_j \otimes x_{j+2} \otimes \cdots \otimes x_n$  and  $\mathbf{x} = x_{j+2} \cdots x_n$ , (product in  $G$ ). Then

$$\rho_n(\sigma_j)f(x_1 \otimes \cdots \otimes x_n) = \left( \prod_{i=1}^{n-1} \sigma(x_i, x_{i+1} \cdots x_n) \right) q(x_j, x_{j+1})\underline{x}$$

and

$$f(\rho'_n(\sigma_j))(x_1 \otimes \cdots \otimes x_n) = q'(x_j, x_{j+1}) \left( \prod_{\substack{1 \leq i \leq j-1 \text{ or} \\ j+2 \leq i \leq n-1}} \sigma(x_i, x_{i+1} \cdots x_n) \right) \sigma(x_j \triangleright x_{j+1}, x_j \mathbf{x}) \sigma(x_j, \mathbf{x})\underline{x}.$$

These expressions are equal if and only if

$$\sigma(x_j, x_{j+1} \mathbf{x}) \sigma(x_{j+1}, \mathbf{x}) \sigma(x_j \triangleright x_{j+1}, x_j) = \sigma(x_j \triangleright x_{j+1}, x_j \mathbf{x}) \sigma(x_j, x_{j+1}) \sigma(x_j, \mathbf{x}) \quad (\text{A.18})$$

Applying (5.13) to  $\{x_j, x_{j+1}, \mathbf{x}\}$  on the left hand side of (A.18) and to  $\{x_j \triangleright x_{j+1}, x_j, \mathbf{x}\}$  on the right hand side we obtain  $\sigma(x_j, x_{j+1}) \sigma(x_j x_{j+1}, \mathbf{x}) \sigma(x_j \triangleright x_{j+1}, x_j)$  on both sides.  $\square$

*Proof of Corollary 5.3.* For  $n \geq 2$ , let  $Q_n$  be the quantum symmetrizer corresponding to the  $B_n$ -representation  $\rho_n$  associated with  $(X, q)$ . Now  $\widehat{\mathcal{B}(X, q)}_d \simeq \mathcal{B}(X, q)$  if and only if the natural algebra projection  $\widehat{\mathcal{B}(X, q)}_d \rightarrow \mathcal{B}(X, q)$  is a linear isomorphism, that is, if and only if for each  $n > d$  the vector spaces  $(\mathbb{k}X)^{\otimes n} / \ker(Q_n)$  and  $(\mathbb{k}X)^{\otimes n} / \left( \bigoplus_{j=1}^d \ker(Q_j) \right) \cap (\mathbb{k}X)^{\otimes n}$  have the same dimension. Here,  $\left( \bigoplus_{j=1}^d \ker(Q_j) \right)$  denotes the ideal generated by  $\bigoplus_{j=1}^d \ker Q_j$  in  $T(\mathbb{k}X)$ . The dimension of the above quotients depends only on the isomorphism class of  $\rho_n$  for any  $n$ . The claim follows from Proposition A.1.  $\square$
