## ABSTRACT

We conducted a search for new ultracool companions to nearby white dwarfs using multiple methods, including the analysis of colors and examination of images in both the optical and the infrared. Through this process, we identified fifty-one previously unrecognized systems with candidate ultracool companions. Thirty-one of these systems are resolved in at least one catalog, and all but six are confirmed as co-moving companions via common proper motion and consistent parallax measurements (when available). We have followed up four co-moving companions with near-infrared spectroscopy and confirm their ultracool nature. The remaining twenty candidates are unresolved, but show clear signs of infrared excess which is most likely due to the presence of a cold, low-mass companion or a dusty circumstellar disk. Three of these unresolved systems have existing optical spectra that clearly show the presence of a cool stellar companion to the white dwarf primary via spectral decomposition. These new discoveries, along with our age estimates for the primary white dwarfs, will serve as valuable benchmark systems for future characterization of ultracool dwarfs.

## 1. INTRODUCTION

The first L-dwarf (GD 165B) was discovered as a companion to a nearby white dwarf (Becklin & Zuckerman 1988). While thousands of L, T, and Y type dwarfs have been discovered since, the number of confirmed substellar companions to white dwarf primaries has remained relatively small. Other L, T, and Y type companions to white dwarfs include PHL 5038B (Steele et al. 2009), LSPM J1459+0857B (Day-Jones et al. 2011), WD 0806-661B (Luhman et al. 2011), Wolf 1130C (Mace et al. 2013), LSPM J0241+2553B (Deacon et al. 2014), LSPM J0055 + 5948AB (Meisner et al. 2020), COCONUTS-1B (Zhang et al. 2020), SDSS J222551.65+001637.7B (French et al. 2023), and VVV 1256–62AB (Zhang et al. 2024b). Several more candidates have also recently been

uncovered (e.g., Kiwy et al. 2022; Rothermich et al. 2024) and are awaiting spectroscopic confirmation.

Despite their relative rarity, each system containing a white dwarf with a resolved ultracool dwarf (spectral type later than  $\sim$ M7) companion holds great value as a benchmark system. It is typically very difficult to determine a precise age of a solitary ultracool dwarf, and often their distances are difficult to measure because of their inherent faintness. If a cool companion can be physically tied to a white dwarf primary, the age and distance of the white dwarf, which are often much easier to determine, can be applied to the cold secondary.

For objects with masses below the substellar limit (brown dwarfs), companionship can be especially valuable because brown dwarfs cool over time, resulting in a degenerate relationship between age, effective temperature ( $T_{\text{eff}}$ ), and mass. White dwarf primaries with

measurable ages can break this degeneracy leading to much more precise physical property determination for any brown dwarf companion (e.g., Luhman et al. 2011; Mace et al. 2018; Zhang et al. 2020). White dwarfs in particular have very predictable cooling rates, which is why they are often used to determine the ages of nearby stars (e.g., Fouesneau et al. 2019; Qiu et al. 2021; Baig et al. 2024), stellar clusters (e.g., Salaris & Bedin 2018; Lodieu et al. 2019a,b; Heyl et al. 2022), and larger populations (e.g., Kilic et al. 2019).

Additional low-mass companions to white dwarfs have been found through indirect means, such as radial velocity variations (e.g., Maxted et al. 2006; Casewell et al. 2012; Farihi et al. 2017), photometric transits (e.g., Beuermann et al. 2013; Parsons et al. 2017; Casewell et al. 2020b), or photometric/spectral decomposition (e.g., Farihi & Christopher 2004; Dobbie et al. 2005; Steele et al. 2011, 2013; Casewell et al. 2018, 2020a; Owens et al. 2023). These systems, however, are often products of post-common envelope evolution. While their utility as age benchmarks is not as clear as with wide ultracool companions, these systems provide rare laboratories for studying the effects of radiation on substellar atmospheres.

We have used the substantial increase in the number of known nearby (<100 pc) white dwarfs enabled by Gaia (Gaia Collaboration et al. 2021a) in Gentile Fusillo et al. (2021) to search for new ultracool companions in the solar neighborhood. We describe our candidate selection methods in Section 2, follow-up observations in Section 3, system properties in Section 4, an analysis of newly discovered systems in Section 5, and provide a conclusion in Section 6.

## 2. CANDIDATE SEARCH

### 2.1. *The White Dwarf Sample*

Our initial list of white dwarfs came from Gentile Fusillo et al. (2021) which is derived from the Gaia Early Data Release 3 (Gaia Collaboration et al. 2021a) catalog and contains  $\sim 1.3$  million likely white dwarfs. Our objective is to search for ultracool companions, which are inherently faint. We therefore limited our initial sample to white dwarfs within 100 pc ( $\varpi \geq 10$  mas). This distance requirement resulted in a candidate list of 16,959 objects.

We employed three different search methods with this sample in order to identify a comprehensive set of both unresolved and resolved candidate companions. These three methods included identifying color outliers, visually inspecting optical and infrared images of each white dwarf for cool companions, and finding ultracool candidates using Gaia astrometry and photometry. Each

method is described in detail in the following three sections.

#### 2.1.1. *Method I: Color Cuts*

This method involved identifying color-selected outliers within our sample of white dwarf candidates. We cross-matched each source with the nearest detection in the CatWISE2020 catalogue (Marocco et al. 2021). We propagate the positions of each candidate white dwarf to the CatWISE 2020 epoch ( $\sim 2015$ ) using Gaia proper motions and use a 5'' search radius. We use the proper motion corrected CatWISE 2020 photometry (e.g., w1mpro\_pm and w2mpro\_pm) for all sources. We also cross-matched each white dwarf with available near-infrared surveys using proper motion corrected coordinates, including the UKIRT Hemisphere Survey (UHS; Dye et al. 2018); the UKIRT Infrared Deep Sky Survey (UKIDSS) Large Area Survey (LAS; Lawrence et al. 2007), Galactic Plane Survey (GPS; Lucas et al. 2008), and Galactic Clusters Survey (GCS; Lawrence et al. 2007); the Visible and Infrared Survey Telescope for Astronomy Hemisphere Survey (VHS; McMahon et al. 2013), VISTA Variables in the Via Lactea (VVV; Minniti et al. 2010), VISTA Magellanic Clouds (VMC; Cioni et al. 2011), and VISTA Kilo-degree Infrared Galaxy (VIKING; Edge et al. 2013) surveys. We then created several color-color plots using Gaia, near-infrared, and CatWISE magnitudes.

Using a sample known white dwarf-brown dwarf systems from the literature (including both resolved and unresolved companions), we searched for color combinations that differentiated the known white dwarf-brown dwarf sample from the rest of the white dwarf population. We determined that the  $G_{\text{BP}} - G_{\text{RP}}$  vs.  $G - W2$  color color diagram clearly distinguished these two populations. The Gaia filters have pivot wavelengths of 621.79 nm, 510.97 nm, and 776.91 nm for  $G$ ,  $G_{\text{BP}}$ , and  $G_{\text{RP}}$ , respectively (Riello et al. 2018), while the WISE W2 filter has a reference wavelength of 4.6028  $\mu\text{m}$  (Wright et al. 2010). The non-excess white dwarfs show a clear correlation between  $G_{\text{BP}} - G_{\text{RP}}$  and  $G - W2$  colors, with redder  $G_{\text{BP}} - G_{\text{RP}}$  colors corresponding to redder  $G - W2$  colors. Both of these colors have been shown to correlate with absolute  $G$ -band magnitudes, with redder colors corresponding to fainter absolute magnitudes (e.g., Gaia Collaboration et al. 2018; Kirkpatrick et al. 2024). Thus this trend can generally be viewed as a temperature sequence, with the coldest white dwarfs having the reddest  $G_{\text{BP}} - G_{\text{RP}}$  and  $G - W2$  colors. We selected as candidates those objects with  $G_{\text{BP}} - G_{\text{RP}}$  colors less than  $0.417 \times (G - W2) - 0.10$  mag (see Figure 1), which cleanly selected a large sample of known, blended

**Figure 1.**  $G_{\text{BP}} - G_{\text{RP}}$  vs.  $G - \text{W2}$  colors for Gaia white dwarfs within 100 pc from Gentile Fusillo et al. (2021). Objects on the normal white dwarf color sequence are displayed as orange dots. Objects showing signs of infrared excess were selected as having redder  $G - \text{W2}$  colors than the dashed line. The color positions of previously known excess sources and newly discovered excess candidates selected via Method I are shown as blue squares and red diamonds, respectively. Rejected excess candidates are shown with grey x symbols.

white dwarf/ultracool dwarf systems. However, this color selection criteria still suffered from significant contamination, mostly from blending with bright sources with small separations. We attempted to eliminate spurious candidates by first flagging those sources with another Gaia source within  $3''$ , thereby eliminating many white dwarf candidates that were blended with a nearby, bright Gaia source. We also required CatWISE2020 W2 magnitudes to have a signal-to-noise ratio (S/N) greater than 10.

These cuts resulted in a total of 3,095 candidates. Each of these candidates was then individually inspected using available optical and infrared images. The vast majority of these sources still showed clear signs of contamination, typically in the form of blending with an unrelated nearby source. The remaining sources, highlighted in Figure 1, either showed no clear contamination, or were found to have a resolved companion within a few arcseconds.

### 2.1.2. Method II: Visual Inspection

This method entailed the manual inspection of available optical images, such as those from the Panoramic Survey Telescope and Rapid Response System (Pan-STARRS (PS1); Chambers et al. 2016) and the Dark Energy Survey (DES; Abbott et al. 2021). For each of the 16,959 objects in our white dwarf sample, we inspected optical images (when available) to identify by-eye any sources within  $\sim 30''$  with exceptionally red optical colors. A search radius of  $30''$  was chosen because it is sufficiently large to expand the search area covered by Method I, but is also small enough to not be subject to an excessive amount of false positives. While this search recovered some of the same sources found using the method in Section 2.1.1 that were resolved in optical or near-infrared images, but not resolved in the Wide Field Infrared Survey Explorer (WISE; Wright et al. 2010) imagery, it was also sensitive to wider sep-

aration companions that would not easily be identified by colors of the white dwarf alone.

Red colors do not guarantee that a candidate companion is co-moving with the white dwarf primary. For those with Gaia parallaxes and proper motions, we ensured consistency between candidate companions and the nearby white dwarfs. For those candidate companions not in Gaia, we either used proper motions from relevant catalogs, such as CatWISE2020 or the NOIRLab Source Catalog DR2 (NSC; Nidever et al. 2021), or calculated proper motions from available catalog detections from UKIDSS, UHS, or PS1. For UHS and UKIDSS, positions were calibrated using the Gaia DR3 reference frame following Schneider et al. (2023). For PS1, detections were taken directly from the DR2 catalog. If detections existed in UKIRT and PS1 catalogs, they were not mixed to avoid systematics between catalogs. Time baselines were several years from each catalog, and thus parallactic motion should have a negligible effect on the resulting proper motions. We ensured that companion candidates had proper motions and parallax (when available) measurements that agreed to within  $5\sigma$ , or had proper motion measurements with differences less than  $5 \text{ mas yr}^{-1}$  and parallax measurement differences less than 1 mas. The second selection criteria was necessary for pairs with exceptionally small measurement uncertainties. For example, while the A and B components of the  $4''$  separation WD J1046+6054AB system have  $\mu_\alpha$  and  $\mu_\delta$  differences of only 3.2 and 2.7 mas  $\text{yr}^{-1}$ , respectively, their small uncertainties result in  $18\sigma$  and  $13\sigma$  disagreements.

There are two exceptions to the above requirements. The first is the companion candidate to WD J001237.06–492422.81, which initially had proper motion differences of less than  $2\sigma$  using the relatively imprecise proper motion measurement of the companion candidate from CatWISE 2020 (Marocco et al. 2021). A more precise proper motion measurement was later found in NSC DR2 (Nidever et al. 2021), resulting in larger discrepancies between  $\mu_\alpha$  ( $14\sigma$ ) and  $\mu_\delta$  ( $4\sigma$ ) components. While this object is still listed in Table 4, it is unlikely to be a physical pair. Second, the putative companion to WD J211901.60+420617.34 was observed spectroscopically before being fully vetted kinematically. We include it in Table 4 despite its unlikely physical nature. For a few candidates, we were unable to produce a proper motion precise enough to clearly establish companionship. We retain these sources for completeness, but label them as “unreliable” until more precise proper motions can be measured.

We also estimated spectral types for each candidate companion. The focus of this work is to identify new

companions with spectral types  $\sim\text{M7}$  and later. We used Gaia parallaxes of candidate companions when available, or the parallax of the putative white dwarf primaries, to calculate absolute  $G$ -,  $J$ - and  $K$ -band magnitudes. We compared these values to the absolute  $G$ -band magnitude versus spectral type table from Kiman et al. (2019), absolute  $J$ - and  $K$ -band values from Pecaut & Mamajek (2013), and the absolute  $J$ - and  $K$ -band versus spectral type relations from Schneider et al. (2023) to estimate spectral types for each companion. Estimated spectral types from different passbands generally agreed to within  $\pm 1$  subtype. In cases where the different relations resulted in different spectral type estimates, the median type was chosen. Candidates with estimated types of  $\sim\text{M7}$  and later were retained.

During the visual examination of optical images for objects from Gentile Fusillo et al. (2021), we identified two objects that appeared unlikely to be white dwarfs based on their red-optical colors (WD J224600.88–060947.02 and WD J235432.47+080404.64). WD J224600.88–060947.02 was previously identified by O’Brien et al. (2024) as a likely brown dwarf contaminant in the Gentile Fusillo et al. (2021) sample. We suggest WD J235432.47+080404.64 is also likely a low-mass star or brown dwarf. Using Gaia parallaxes and photometry from VHS for WD J224600.88–060947.02 and UKIDSS LAS for WD J235432.47+080404.64, we find absolute magnitude consistent with spectral types of  $\sim\text{L2}$  for WD J224600.88–060947.02 and  $\sim\text{L1}$  for WD J235432.47+080404.64.

### 2.1.3. Method III: Gaia Comparisons

Our final method of identifying potential ultracool companions used available Gaia astrometry and photometry for objects within the vicinity of each nearby white dwarf. We identified every object with Gaia distances  $<110$  pc within  $60''$  of each object in our white dwarf sample. We chose 110 pc to account for some uncertainty in both white dwarf and candidate companion parallax measurements. For each object within  $60''$  of one of our white dwarf targets that had a distance measurement within 110 pc, we individually checked for relative proper motion and parallax consistency, to be further evaluated with the CoMover tool (see Section 2.2.2). We further selected for possible ultracool companions by identifying those sources with absolute  $G$ -band magnitudes  $>14.5$  mag, which corresponds to a spectral type of  $\sim\text{M8}$ . We did not require any further color-cuts based on Gaia colors, as the redness of ultracool sources can make the Gaia photometry unreliable (Smart et al. 2019). However, we did note that

some white dwarfs were found to match to each other (i.e., white dwarf-white dwarf systems). These candidate systems are listed in Appendix A.

## 2.2. Final Candidates

### 2.2.1. Unresolved Candidates

Our unresolved candidates were found solely through Method I (Section 2.1.1). A total of seventy-four unresolved candidate systems were identified. We searched the literature for each candidate to determine if these objects were previously known to have infrared excess, which could be indicative of an unresolved companion or dusty debris disk. Fifty-seven of our unresolved candidates were determined to have been previously identified as having either a known debris disk, an unresolved companion, or general infrared excess. These sources are listed in Table 1. Seventeen of our unresolved candidates had not been previously reported. These objects are listed in Table 2 with their corresponding Gaia and CatWISE2020 photometric measurements. Optical and WISE images for each of these candidates is shown in Figure 2. The infrared excess of these white dwarfs could suggest the presence of a surrounding dust disk, or alternatively an unresolved low-mass companion (explored further in Section 5).

We note that the results of our search for white dwarfs showing signs of excess infrared emission are different from previous searches because of our specific color-selection criteria and the construction of our input sample. Because we are most interested in new, cold companions to white dwarfs, a distance-limited sample is most appropriate, as such companions are inherently faint. Other infrared-excess searches focused on white dwarfs (e.g., Favieres et al. 2024) instead use a magnitude limited sample, which would be sensitive to excess emission around bright white dwarfs beyond 100 pc that are not included in our sample.

### 2.2.2. Resolved Candidates

A combined total of 54 candidate white dwarf + ultracool dwarf systems that were resolved in at least one cat-

alog were identified using Methods I, II, III. A literature search revealed that 23 of these systems had been discovered previously. These recovered systems are listed in Table 3.

We found a total of 31 new systems with white dwarf primaries and candidate ultracool dwarf companions where the companions were resolved in at least one survey. Astrometric and photometric information are provided in Tables 4, 5, and 6. Available absolute magnitudes and spectral type estimates are given in Table 7. Cutout optical images of the candidate systems are shown in Figure 3. Note that the “unreliable” candidates are not included in Figure 3. All candidate systems were evaluated with the `CoMover` comoving probability tool, which determines the Bayesian probability of two sources being a physically comoving pair. `CoMover` probabilities are provided in Table 4.

Several of these resolved candidate companions had been noted as candidate ultracool dwarfs or high-proper motion objects in previous surveys, but had not been recognized as having a white dwarf companion. WD J014953.55–612916.97B, WD J023020.88–344749.38B, WD J044713.58–582318.04B, WD J104627.91+605448.32B, and WD J211901.60+420617.34B were each selected as Gaia ultracool dwarf candidates in Reylé (2018). WD J044713.58–582318.04B was also previously identified as a high proper motion source in Deacon & Hambly (2007) and Kirkpatrick et al. (2016). WD J104627.91+605448.32B has an optical spectral type of M9 in Kiman et al. (2019). WD J080648.05+221551.65B was selected as an L-type candidate object in Gálvez-Ortiz et al. (2017). Lastly, WD J141835.29+092919.68B was previously identified as a photometric L dwarf candidate in Skrzypek et al. (2016).

Several of these sources have also been identified as ultracool dwarf candidates by citizen scientists working with the Backyard Worlds: Planet 9 project (Kuchner et al. 2017). We recognize the contributions of these scientists in the footnotes of Table 4.

**Figure 3.** Three color RGB images of all new resolved candidates. White dwarf primaries are marked with yellow lines while candidate ultracool companions are marked with red lines. The WD 0807-5350 system has only  $r$ - and  $g$ -band DECam images, and thus the candidate companion is difficult to see in the image (though is resolved in Gaia). Note that the “unreliable” candidates are not included in this figure.

### 3. OBSERVATIONS

#### 3.1. IRTF/SpeX

Four of our resolved candidate companions were observed with the SpeX spectrograph (Rayner et al. 2003) at NASA’s Infrared Telescope Facility (IRTF). Observations for WD J0806+2215B were taken on 11 November 2018 and for WD J2025+3515B, WD J2119+4206B, and WD J2355+5131B on 13 August 2024. All observations were done in prism mode with the  $0''.8$  slit, which results in a resolving power of  $\approx 200$  across  $0.8\text{--}2.5 \mu\text{m}$ . The spectra were reduced using the Spextool reduction package (Cushing et al. 2004; Vacca et al. 2003). The final reduced spectra is shown in Figure 4. Comparing to near-infrared L and T dwarf spectral standards from Burgasser et al. (2006) and Kirkpatrick et al. (2010), we find that the best match at the *J*-band for WD J0806+2215B is the L3 standard (2MASSW J1506544+132106; Burgasser 2007). For WD J2025+3515B, WD J2119+4206B, and WD J2355+5131B, we find the best matching standard at *J*-band to be the M8 standard (VB 10; Burgasser et al. 2004).

#### 3.2. Gemini/GMOS

One white dwarf primary (WD J0400–2611) was observed with the Gemini-North Multi-Object Spectrograph (GMOS; Hook et al. 2004) as part of program GN-2021A-Q-316 (PI: Debes). WD J0400–2611 was observed with the R400 grating using the  $1''$  slit with  $2\times 2$  binning centered on  $0.764 \mu\text{m}$ . The purpose of this observation was to examine the spectrum for the presence of hydrogen or helium to determine whether this object had a DA or non-DA composition. We obtained 4,300 s exposures that were then stacked during the reduction. The spectra were reduced using the DRAGONS reduction software (Labrie et al. 2019, 2023), which performs the bias, flat-field, bad pixel and wavelength corrections as well as the response function determined from a standard star. The  $\text{H}\alpha$  absorption line, which indicates that this object is a DA white dwarf, is shown in Figure 5.

### 4. SYSTEM PROPERTIES

#### 4.1. $T_{\text{eff}}$ and $\log(g)$

We gathered the basic fundamental properties of all candidate systems by searching the literature for  $T_{\text{eff}}$  and  $\log(g)$  values of the primary white dwarf and taking

the most precise values available if more than one estimate existed. Most of these measurements come from newly available low-resolution Gaia XP spectra (e.g., Jiménez-Esteban et al. 2023; Vincent et al. 2024). These values are provided in Table 8.

#### 4.2. Spectral Types

We searched the literature for spectral types for the candidate unresolved systems and the white dwarf primaries of resolved co-moving systems. Spectral types, including our type found for WD J0400–2611 from Section 3, are given in Table 8.

#### 4.3. Ages

We determined age estimates for all of our candidate systems using `wdwarfdate` (Kiman et al. 2022). `wdwarfdate` estimates the total ages of white dwarfs by combining their cooling ages with the main-sequence lifetimes of their progenitor stars. It uses the Initial-to-Final Mass Relation (IFMR), and in this study, we used the highest-accuracy Cummings et al. (2018) (both MIST and PARSEC-based), which links the white dwarf’s mass to the mass of its progenitor. The package incorporates cooling models from Bédard et al. (2020) which detail the cooling process of white dwarfs based on their mass, temperature, and atmospheric composition. The package also incorporates stellar evolution models from Dotter (2016) and Choi et al. (2016) to estimate the main-sequence lifetime of the progenitor star. `wdwarfdate` also handles DA and non-DA white dwarfs differently. For DA white dwarfs, the models from Bédard et al. (2020) address their slower cooling rates, considering that the hydrogen layer is more insulating than a non-DA helium counterpart (Fontaine et al. 2001). These non-DA counterparts also have their own distinct cooling model, so as to best estimate an age with models most representative of the actual composition of the object. If no spectral type was found for an object in our sample, we evaluate both DA and non-DA ages for that system. Some objects had conflicting spectral types in the literature (e.g., WD J001419.17–475719.58 is typed as non-DA in Jiménez-Esteban et al. 2023 and DA in Vincent et al. 2024). In these cases, we evaluate both DA and non-DA scenarios and provide both age estimates.

Ages or age limits were determined for all but four of the unresolved candidates (Table 8). WD J1628–0418, WD J1657–1256, and WD J2053+2603 had no available  $T_{\text{eff}}$  or  $\log(g)$  values available in the literature, and WD J2339+2552 has an unusually low  $\log(g)$  value ( $6.88\pm 0.02$ ; Vincent et al. 2024) that is beyond the allowed values of the models considered by `wdwarfdate`.

## 5. ANALYSIS

### 5.1. Spectral Binaries

Several objects (WD J1125–1631AB, WD J1657–1256AB, and WD J2339+2552AB) have available optical spectra from Gaia DR3 (Gaia Collaboration et al. 2021a; De Angeli et al. 2023). We extracted each available spectrum using the GaiaXPy Python library (Ruz-Mieres & Zuzannakr 2024). We inspected each spectrum for potential spectral signatures of low-mass companions. Three objects (WD J1125–1631, WD J1657–1256, and WD J2339+2552) showed clear signs of unresolved binarity with a low-mass companion. We made templates using spectroscopically classified white dwarfs from McCook & Sion (1999) and M and L dwarf standards (Kirkpatrick et al. 1991, 1999). All of the

spectra were absolutely flux-calibrated using Gaia DR3 parallaxes, however we allow for additional multiplicative coefficients to the white dwarf, M dwarf, and L dwarf templates to allow for unaccounted flux discrepancies such as variability or additional unresolved binarity of either the standard or the candidates. The best fitting templates were found via  $\chi^2$ -fitting to the white dwarf + cool dwarf templates. The white dwarfs used in the final fits are GD 140 (DA3; McCook & Sion 1999), EGGR 155 (DA5; McCook & Sion 1999), and EGGR 7 (DA6; McCook & Sion 1999), while the M dwarfs are Gl 402 (M4; Kirkpatrick et al. 1991) and VB 8 (M7; Henry et al. 2004). The best fitting templates to the Gaia spectra of WD J1125–1631, WD J1657–1256, and WD J2339+2552 are shown in Figure 6.

### 5.2. Old Systems

**Table 7.** Candidate Companion Spectral Types

WD J2355+5131B	15.615±0.144	11.187±0.144	10.133±0.145	M8
WD J1125–1631B	...	...	...	M7 <sup>c</sup>
WD J1657–1256B	...	...	...	M4 <sup>c</sup>
WD J2339+2552B	...	...	...	M7 <sup>c</sup>

<sup>a</sup>Spectral types in square brackets are estimates based on the absolute magnitudes listed and spectral type versus absolute magnitude relations from Pecaut & Mamajek (2013), Kiman et al. (2019), and Schneider et al. (2023), while those spectral types without square brackets are those that have been confirmed spectroscopically.

<sup>b</sup> WD J1046+6054B has an optical spectral type of M9 from Kiman et al. (2019).

<sup>c</sup> These spectral types were determined via spectral decomposition in Section 5.1.

**Figure 4.** IRTF/SpeX spectra of four newly discovered companions. All spectra are normalized between 1.27 and 1.29  $\mu\text{m}$ . WD J0806+2215B is best matched to the L3 spectral standard (2MASSW J1506544+132106; [Burgasser 2007](#)), while WD J2025+3515B, WD J2119+4206B, and WD J2355+5131B are best matched to the M8 spectral standard (VB 10; [Burgasser et al. 2004](#)).

**Figure 5.** Gemini/GMOS-N spectrum of WD J0400–2611 showing clear H $\alpha$  absorption and a lack of He lines.

WD J0012–4924AB, WD J0824–2546AB, WD J1046+6054AB, WD J1715–1910AB, WD J2005+6932AB, and WD J2353–4325AB all have age estimates  $>10$  Gyr, making them potential benchmark systems with advanced ages.

WD J1046+6054B has a confirmed optical spectral type of M9 from [Kiman et al. \(2019\)](#). While no suggestion of low-metallicity was made for this source in that work, the calculated tangential velocity ( $V_{\tan}$ ) of  $\sim 250$  km s $^{-1}$  supports the old age estimate for this system. WD J0824–2546B, WD J1715–1910B, WD J2005+6932B all have estimated spectral types of late-M similar to WD J1046+6054B. The WD J1715–1910AB system may be particularly valuable with the oldest age estimate in the entire sample presented in this work ( $11.83^{+2.10}_{-2.08}$  Gyr).

WD J0012–4924AB is a system that needs future astrometric confirmation of the physical association of the potential companion and the white dwarf. If confirmed, the candidate companion has an estimated spectral type of  $\sim$ L3. Follow-up spectroscopy could reveal this as a potential benchmark system containing an L subdwarf with a well-constrained age, joining a relatively rare group that includes VVV 1256–62AB ([Zhang et al. 2024b](#)).

WD J2353–4325A does not have a confirmed white dwarf spectral type, but has an age of  $11.12^{+2.03}_{-1.92}$  Gyr based on the DA cooling model and  $9.92^{+2.90}_{-1.27}$  Gyr based on the non-DA model. The companion in this system, WD J2353–4325B, has a spectral type estimate of  $\sim$ T5. Therefore this system could be especially valuable as it contains a mid-T dwarf with an exceptionally old age. The cloudless Sonora models ([Marley et al. 2021](#)) give a mass estimate of  $70.4 \pm 3.3 M_{\text{Jup}}$  and  $69.9 \pm 2.8 M_{\text{Jup}}$  for a T5 dwarf at the DA and non-DA age of the primary, respectively.

### 5.3. Notes on Individual Systems

#### 5.3.1. WD J0004+7401

Confirmation of infrared excess with higher resolution follow-up infrared imaging (e.g., [Lai et al. 2021](#)) or additional photometric detections at longer wavelengths for this unresolved source can help to distinguish between true infrared excess due to a dusty debris disk or some contaminating flux from another source. None of our seventeen excess systems have additional infrared imaging from the Spitzer Space Telescope in the Spitzer Heritage Archive ([Wu et al. 2010](#)). We further looked for longer wavelength detections at  $12\text{ }\mu\text{m}$  and  $22\text{ }\mu\text{m}$  in the AllWISE catalog ([Kirkpatrick et al. 2014](#)), as the CatWISE2020 catalog only includes W1 and W2 photometry ([Marocco et al. 2021](#)). Only three objects have  $12\text{ }\mu\text{m}$  (W3) detections (WD J0004+7401, WD J1125–1631, and WD J1657–1256), and there are no detections at  $22\text{ }\mu\text{m}$  (W4). The W3 detections of WD J1125–1631 and WD J1657–1256 are most likely due to unresolved stellar companions, as discussed in the next paragraph. The W3 detection of WD J0004+7401 may be evidence of circumstellar material for this source. Its extra-red nature is visible in Figure 2, with a reddish hue in the WISE composite image that is not seen for the other sources in that figure due to the brighter than typical W3 flux for this source. Confirmation is possible with future high-resolution infrared images or mid- to far-infrared spectroscopy. The total age for this white dwarf is  $>5.64^{+4.57}_{-2.38}$  Gyr if a hydrogen dominated atmosphere and  $>6.08^{+2.05}_{-2.69}$  Gyr in the non-DA case. With a  $T_{\text{eff}} \sim 4300$ –4400 K, this would be one of the coldest and oldest white dwarfs to show infrared excess due to a dusty disk (e.g., [Debes et al. 2019](#)).

#### 5.3.2. WD J0024–1631

This unresolved source is almost certainly a white dwarf + low-mass companion system, as a very red point source can be seen blended with the white dwarf primary in the PS1 images in Figure 2. However, this source was not resolved into two detections in the PS1 DR2 catalog at this position. Because this pair was not resolved in any existing catalog, it is included in our list of unresolved candidates. High-resolution imaging of this system and any resulting unblended photometry would allow for an accurate spectral type estimate for this companion.

#### 5.3.3. WD J0735–7944AB

This white dwarf in this resolved system has the highest  $T_{\text{eff}}$  in our sample ( $28063 \pm 836$  K; [Jiménez-Esteban et al. 2023](#)) and consequently has the youngest age estimate ( $0.21 \pm 0.02$  Gyr). The high  $T_{\text{eff}}$  of this source

**Figure 6.** Spectral binary fits to the Gaia spectra of WD J1125–1631, WD J1657–1256, and WD J2339+2552. White dwarf spectra are shown in cyan, M dwarf spectra are shown in red, and the combined white dwarf + M dwarf templates are shown in purple. The observed Gaia spectra for these three unresolved candidates are shown in black.

is supported by the values reported in Gentile Fusillo et al. (2021) ( $28583 \pm 1173$  K) and Vincent et al. (2024) ( $35337 \pm 1290$  K). We note that this is one of our “unreliable” systems for which a detailed astrometric analysis of the potential companion is needed. However, if confirmed, we estimate a spectral type of  $\sim$ L6 for the putative companion. At the age of WD J0735–7944A, an L6 companion would have a mass of  $34 \pm 5 M_{\text{Jup}}$  according to the solar metallicity hybrid-grav Sonora Diamond-back models from Morley et al. (2024).

### 5.3.4. WD J0806+2215AB

The companion in this resolved system was observed with IRTF/SpeX (Figure 4) and was found to have a spectral type of L3. The spectrum is slightly redder than the L3 standard, which is unlikely to be related to a young age (i.e., low surface gravity), as the age of the system is found to be  $5.56^{+3.08}_{-0.98}$  Gyr. Other factors can cause redder colors, such as enhanced metallicity (e.g., Looper et al. 2008; Zhang et al. 2024a) or inclination angle (e.g., Vos et al. 2017; Suárez et al. 2023). We find a  $T_{\text{eff}}$  of  $1841 \pm 147$  K using the spectral type vs.  $T_{\text{eff}}$  relations from Kirkpatrick et al. (2021), leading to a mass

estimate of  $77.4 \pm 2.6 M_{\text{Jup}}$  using the age of the system and the solar-metallicity hybrid-grav models of Morley et al. (2024). This is just above the hydrogen burning limit for the hybrid models ( $70.2 M_{\text{Jup}}$ ; Morley et al. 2024) making this a likely low-mass, stellar companion.

### 5.3.5. WD J0950+1309AB

Of the remaining resolved candidates with reliable astrometry that give a high probability of physical association with a white dwarf primary not already discussed previously, WD J0950+1309B is the lone object with a spectral type estimate clearly in the substellar regime ( $\sim$ L8). Spectroscopic confirmation for the primary and secondary are needed for this system, which could become a benchmark object with a well-determined age at the L/T transition.

### 5.3.6. WD J2119+4206

The possible companion in this resolved system is all but ruled-out as physically associated by the CoMover results in Table 4. The companion candidate was followed-up spectroscopically (Section 3) before being evaluated with CoMover, and found to have a spectral type of M8. This system is likely a chance alignment.

## 6. CONCLUSIONS

In this study, we identified and compiled a new set of ultracool dwarf companions to white dwarfs within 100 pc using available astrometry and optical and infrared data. Through our search, we identified fifty-one previously unrecognized systems with candidate ultracool companions. Of these, thirty-one are resolved in at least one catalogue, with all but six reliably confirmed as co-moving based on consistent proper motion and parallax measurements (if available). The six unreliable cases will require additional astrometric data to verify their status as companions to the white dwarf primary.

Follow-up near-infrared spectroscopy of four of our resolved co-moving candidates confirmed their ultracool nature with three confirmed to be M8, and one a likely stellar source with an L3 spectral type. However, one of these systems (WD J2119+4206) was deemed unlikely to be physically associated in our astrometric analysis. Three of our unresolved sources were confirmed as having cool stellar companions via spectral decomposition of available optical spectra from Gaia. The remaining candidates will benefit from detailed follow-up spectroscopy to further constrain the natures of these systems.

## 7. ACKNOWLEDGEMENTS

The authors acknowledge support from the Science and Engineering Apprenticeship Program (SEAP) of the Office of Naval Research.

This publication makes use of data products from the *Wide-field Infrared Survey Explorer*, which is a joint project of the University of California, Los Angeles, and the Jet Propulsion Laboratory/California Institute of Technology, and NEOWISE which is a project of the Jet Propulsion Laboratory/California Institute of Technology. *WISE* and NEOWISE are funded by the National Aeronautics and Space Administration. Part of this research was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration.

This publication makes use of data products from the UKIRT Hemisphere Survey, which is a joint project of the United States Naval Observatory, the University of Hawaii Institute for Astronomy, the Cambridge University Cambridge Astronomy Survey Unit, and the University of Edinburgh Wide-Field Astronomy Unit (WFAU). This project was primarily funded by the United States Navy. The WFAU gratefully acknowledges support for

this work from the Science and Technology Facilities Council through ST/T002956/1 and previous grants.

The Pan-STARRS1 Surveys (PS1) and the PS1 public science archive have been made possible through contributions by the Institute for Astronomy, the University of Hawaii, the Pan-STARRS Project Office, the Max-Planck Society and its participating institutes, the Max Planck Institute for Astronomy, Heidelberg and the Max Planck Institute for Extraterrestrial Physics, Garching, The Johns Hopkins University, Durham University, the University of Edinburgh, the Queen’s University Belfast, the Harvard-Smithsonian Center for Astrophysics, the Las Cumbres Observatory Global Telescope Network Incorporated, the National Central University of Taiwan, the Space Telescope Science Institute, the National Aeronautics and Space Administration under Grant No. NNX08AR22G issued through the Planetary Science Division of the NASA Science Mission Directorate, the National Science Foundation Grant No. AST-1238877, the University of Maryland, Eotvos Lorand University (ELTE), the Los Alamos National Laboratory, and the Gordon and Betty Moore Foundation.

This publication has made use of the Python package GaiaXPY, developed and maintained by members of the Gaia Data Processing and Analysis Consortium (DPAC), and in particular, Coordination Unit 5 (CU5), and the Data Processing Centre located at the Institute of Astronomy, Cambridge, UK (DPCI).

This research uses services or data provided by the Astro Data Lab, which is part of the Community Science and Data Center (CSDC) Program of NSF NOIRLab. NOIRLab is operated by the Association of Universities for Research in Astronomy (AURA), Inc. under a cooperative agreement with the U.S. National Science Foundation.

*Facilities:* Astro Data Lab, IRTF

## APPENDIX

### A. WHITE DWARF-WHITE DWARF SYSTEMS

Our search for cold companions using Gaia (Method III in Section 2) identified many likely white-dwarf-white dwarf systems. Listed in Table 9 are the 115 potential white dwarf-white dwarf systems found through our search where at least one component in the system has an absolute  $G$ -band magnitude  $>14.5$  mag.

**Table 9.** Candidate White Dwarf-White Dwarf Systems
