## Abstract

Adapting named entity recognition (NER) methods to new domains poses significant challenges. We introduce *RapidNER*, a framework designed for the rapid deployment of NER systems through efficient dataset construction. *RapidNER* operates through three key steps: (1) extracting domain-specific sub-graphs and triples from a general knowledge graph, (2) collecting and leveraging texts from various sources to build the *NERsocial* dataset, which focuses on entities typical in human-robot interaction, and (3) implementing an annotation scheme using Elasticsearch (ES) to enhance efficiency. *NERsocial*, validated by human annotators, includes six entity types, 153K tokens, and 99.4K sentences, demonstrating *RapidNER*'s capability to expedite dataset creation.

## 1 Introduction

The natural language processing (NLP) field has grown substantially in recent years, surpassing expectations and creating many new applications. NLP applications are manifestations of NLP tasks, such as information extraction, text generation, language modeling, and the like.

Yet, despite all the progress, adapting existing information extraction systems for NER to new domains and entity types remains a challenge, a fact that is compounded by the need to develop new datasets representative of the new domain, followed by fine-tuning NER classifiers to correctly detect new entity types in the new domain.

Recognizing the need to create NER datasets for new domains and entity types efficiently, we make two succinct contributions: 1) We propose a framework *RapidNER* to annotate NER datasets by utilizing off-the-shelf tools. Specifically, we exploit the search functions inside *ES* and successfully develop an annotation method for NER data. 2) We focus

Figure 1: Our NER dataset aims to support dialogue between humans and robots. New entity types are **Drink, Food, Hobby, Job, Pet, Sport**. We utilize Wikidata to acquire information about entity types.

on human-robot interaction (HRI) applications and develop a new dataset named *NERsocial* comprising the entity types that are suitable for interaction between humans and a social robot<sup>1</sup> (Figure 1). Consequently, we sought texts that represent the natural conversational style embedded in human dialogue. Our textual sources include social media (Reddit) and online forums (Stack Exchange). Aiming for diversity in texts, we included Wikipedia as a complimentary textual source, which provides a rich contextual narrative for all entities. Figure 2 shows all the textual sources.

*NERsocial* is not the first attempt by NER researchers to design new specifications of NE labels to develop NER datasets suited for new domains. We follow the footsteps of domain-specific and unconventional efforts, such as [Epure and Hennequin \(2023\)](#), to create our NER dataset *NERsocial*. *NERsocial* consists of six entity types<sup>2</sup> **drinks, foods, hobbies, jobs, pets, and sports** which are typical

<sup>1</sup>One use-case is that the robot's been deployed as a tutor for kids aged 10 years and below; when the teacher is absent.

<sup>2</sup>The six entity types were sufficient to build the first prototype of a social robot interacting with young kids. More entity types are iteratively added based on use-case.

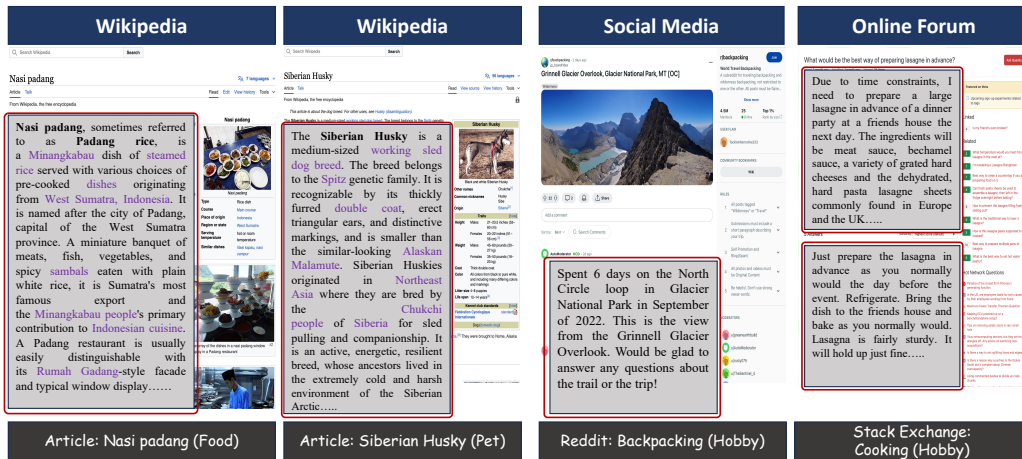

Figure 2: We collected the texts from three sources: **Wikipedia**, **online forums** (Stack Exchange) and **social media** (Reddit). The red box indicates sections containing the texts that we are interested in, for each textual source.

of *social interactions* in HRI, and Figure 1 shows an example of a human-robot dialogue. While creating *NERsocial*, we needed to *acquire* knowledge about each entity type. Consequently, we sought to answer the research question *how can we quickly gather entity information relevant to unseen entities, such as pets?* Hence, we chose the KG approach to gather such entity knowledge in the form of KG triples which guided the development of our NER dataset. This process is summarized in Figure 3. In addition, KG triples enabled us to solve another problem, that is, *how to increase the coverage and diversity of each NE?* Concretely, KG triples guided the extraction of a large number of diverse pages (articles) from Wikipedia. In turn, the pages were the source of sentences used to construct the dataset coupled with the texts gathered from social media and online forums. The last challenge we faced was: *how to annotate the thousands of sentences with less human effort?* We utilized the search functions inside Elasticsearch to develop an annotation scheme that took only a few seconds to *mark* spans of entity mentions, §4.7.

## 2 Related work

Our work focuses on entities specific to HRI and unseen in previous NER datasets. Popular NE include: *Person, Location, Organization, Product, Event, Building, Product*, among others; and NER datasets include: CoNLL2003 (Tjong Kim Sang, 2002), WikiGold (Balasuriya et al., 2009), OntoNotes (Weischedel et al., 2013), WNUT2017 (Derczynski et al., 2017), FEWN-

ERD (Ding et al., 2021), and I2B2 (Stubbs and Uzuner, 2015). Though the above entity types and datasets are sufficient for many applications, utilizing the same datasets for unique domains such as HRI is difficult because HRI includes many “rare entities” such as *pets, leisure activities, popular cuisines, weather&seasons, etc.*. Due to this domain transfer problem, Epure and Hennequin (2023) developed an NER dataset for music recommendations in a conversational assistant. Researchers have also developed many NER datasets to support a plethora of unique applications. Exemplar NER applications and datasets include: biomedical applications, GENIA (Kim et al., 2003), NCBI (Dogan et al., 2014), conversational music recommendation, MusicRecoNER (Epure and Hennequin, 2023), disaster response systems, HarveyNER (Chen et al., 2022), taxonomic entities in biology, TaxoNERD (Le Guillarme and Thuiller, 2022), inter alia. Evidently, in all these applications, it is common practice to develop a dataset characteristic of entity types relevant to the application, followed by fine-tuning a deep learning-based NER classifier to recognize entities. The common sources for texts include Wikipedia, news articles, social media posts TwitterNER7 (Ushio et al., 2022), online forum posts and comments from video streaming platforms like YouTube, WNUT (Derczynski et al., 2017). Datasets created from Wikipedia, social media and posts from online forums are relevant to our work. For example, WikiGold (Balasuriya et al., 2009), WikiANN (Pan et al., 2017), FewRel 2.0 (Gao et al.,

2019) were constructed from either Wikipedia or Wikidata. However, WNUT is most similar in nature to our dataset. Hence, we compared WNUT to our dataset in subsequent sections. Lastly, we have not yet found any similar works that employed ES to annotate NER datasets.

### 3 Overview of RapidNER Framework

To address the problem of scarcity of labeled NER data for applications such as human-robot interaction (or any other application), we developed a framework to quickly collect and annotate texts, resulting in a new NER dataset. The proposed framework is called *RapidNER*, comprising three main steps as described in Algorithm 1.

*First.* We select the knowledge graph,  $G$ ; the source of textual data, that is, the set of all data sources  $D$  from which to collect the texts. In this work, we mainly focused on HRI applications. Hence, we further defined a precise set of conversational topics,  $C$ , for HRI.  $C$  represents the NE.

*Second.* From the chosen graph, i.e., Wikidata or  $G_{Wiki}$ , we extract topic-specific sub-graphs (see Figure 3 and Figure 8) as follows.  $G_{Wiki}$  has many properties (i.e., relations,  $\mathcal{R}$ ), but we employ two properties *instance-of* and *subclass-of* to gather triples  $\mathcal{T}_c$  for each topic  $c$ . Then, we extract the head entities  $\mathcal{H}_t$  of triples in  $\mathcal{T}_c$  to build a collection

of hyponyms for each  $c$ <sup>3</sup>. Lastly, we remove any duplicates in  $\mathcal{H}_t$ . Entries in  $\mathcal{H}_t$  correspond to entity mentions of NE.

*Third.* For each entry in  $\mathcal{H}_t$ , we find the corresponding Wikipedia article and extract text from that article. Texts from many articles are accumulated, split into sentences, and then prepared for annotation. We extend data collection to all the data sources. For all sentences, we deploy ES to mark all spans of text matching with any entries in  $\mathcal{H}_t$ . In this way, we annotate thousands of sentences in a matter of seconds. Next, the annotations are fully human-verified. Annotations of spans of text are converted into BIO tags, creating a novel NER dataset, consisting of pairs of sentences and their BIO tags.

Our new ES-based annotation scheme significantly reduces the time-and-cost required for labeling texts, hence the name *RapidNER*.

Ultimately, *RapidNER* consists of three main components: a knowledge graph (Wikidata), sources of textual data (Wikipedia, Reddit, etc.), and an annotation tool (ES). This process is summarized in Algorithm 1.

## 4 Construction of NERsocial

To construct NERsocial, we utilized the framework introduced in §3. We leverage the wealth of knowledge in  $G_{Wiki}$  and the large number of Reddit posts, Stack Exchange posts, and articles in Wikipedia to build a NER dataset quickly for HRI. We focus on conversational topics or entity types that are typical of social interactions. We describe the process of constructing the dataset in the following sections.

### 4.1 Overview of Dataset Construction

To begin with, we acquired KG knowledge related to six NE, namely, **Drink, Food, Hobby, Job, Pet, Sport**, in the form of KG triples. Then, we utilized the triples to (1) collect hyponyms, thus *entity mentions*, for each NE and (2) guide the retrieval of Reddit&Stack Exchange forums and pages from Wikipedia based on *Page IDs*. Figure 3 (step 1 to step 4) shows the detailed process.

### 4.2 Source Corpus

**Reddit Posts.** The rich conversational parlance embedded within Reddit posts made it an attrac-

---

<sup>3</sup>We imagine  $c$  is a hypernym sharing a relation  $r$  with the hyponym.  $r$  exists in the triples.

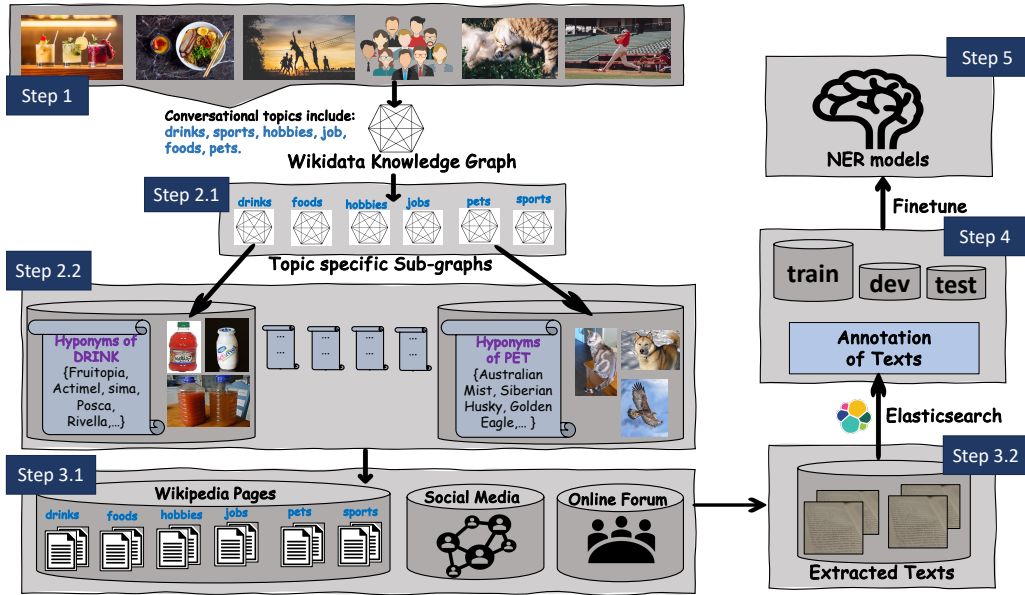

Figure 3: The construction process of *NERsocial*. We gathered millions of triples from Wikidata and used the triples to collect Wikipedia articles. For each Wikipedia article, we extracted paragraphs from the introduction sections, and split them into sentences. Additionally, we collected conversational texts from Reddit and Stack Exchange. For each sentence, we annotated spans of text containing entity mentions with the help of ES. Human annotators verified text-span annotations before the text-spans were converted into NE labels.

tive source of texts for our dataset. Reddit inhibits back and forth interactions between users about a shared topic of interest, housed under a *subreddit*. Therefore, we collected Reddit posts as follows: 1) created a list of subreddits relevant to each entity type<sup>4</sup> 2) leveraged the API to extract texts from the shortlist of subreddits 3) filtered out non-UTF8 characters, XML tags, URLs, emojis, and insignificant punctuation marks. 4) split paragraphs into single sentences using the *nlk* tokenizer. Under each subreddit, we prioritized posts that are most popular and thus convey high user engagement. Moreover, all the chosen subreddits in our study contain more than 4M members.

**Stack Exchange Posts.** In the same vein as extracting Reddit posts, we created a shortlist of forums on Stack Exchange relevant to each entity type. We access the API and collect posts, followed by a text filtering process described above.

**Wikipedia Texts.** We adopt a collection of Wikipedia articles and Wikidata *statements* contained in KDWD<sup>5</sup> dataset. The KDWD dataset con-

sists of 6,985  $G_{Wiki}$  properties, 51M Wikidata items and 141M Wikidata statements. Moreover, 5,343,564 Wikipedia pages are included.<sup>6</sup> We leverage Wikidata properties, items and statements, in combination with Wikipedia pages to create a new NER dataset.

Figure 4 is a UMAP visualization illustrating the diversity of texts from three data sources, Reddit, Stack Exchange, and Wikipedia, contained in our dataset. To create this visualization, we leverage *nlk*<sup>7</sup> to tokenize the texts and to remove all *stop-words*. Then, we deploy *TF-IDF* to vectorize the texts, creating embeddings. Finally, we deployed UMAP and set *#neighbors* to 15, *min distance* to 0.1, *#components* to 2, and *random state* to 42 to visualize the embeddings from three textual sources.

### 4.3 Wikidata Properties

$G_{Wiki}$  has 6,985 *properties*<sup>8</sup>. Table 13 defines the two properties used in this study: *instance-of* & *subclass-of*. These properties, in turn, describe *relations* between two *items* in the KDWD dataset, as

kensho-derived-wikimedia-data

<sup>6</sup>KDWD released the following files: property.csv, statements.csv, item.csv, page.csv, link\_annotated\_text.jsonl

<sup>7</sup>NLTK version is 3.8.1 is used

<sup>8</sup>All properties provided in KDWD property.csv file.

<sup>4</sup>For example, a collection of hobbies is available at [https://www.reddit.com/r/Hobbies/comments/zqwx6c/the\\_hobby\\_master\\_list\\_and\\_their\\_subreddit/](https://www.reddit.com/r/Hobbies/comments/zqwx6c/the_hobby_master_list_and_their_subreddit/).

<sup>5</sup>KDWD can be found here <https://www.kaggle.com/datasets/kenshoresearch/>

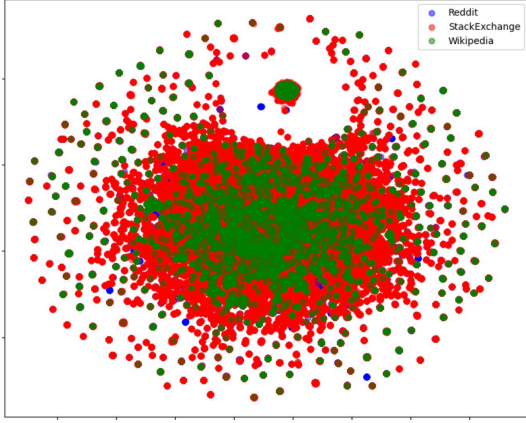

Figure 4: The UMAP visualization shows the diversity of texts from three data sources: Reddit, Stack Exchange, and Wikipedia (best seen in color).

shown in Table 1. We selected the two properties because, in a triple described by either *instance-of* or *subclass-of* in Wikidata, we can strictly ‘set’ head entity as the hyponym and tail entity as the hypernym<sup>9</sup> <sup>10</sup>. In this study, the head entities, i.e., hyponyms constitute the entity mentions, yet the tail entities, i.e., hypernyms, constitute the named entities. This design allows us to gather many hyponyms for each hypernym (Step 2.2 in Figure 3), analogous to *hyponym expansion*. The collection of hyponyms is used for (i) retrieving articles from Wikipedia (Step 3.1 in Figure 3), and (ii) annotation purposes (Step 4 in Figure 3). Further discussion of *Wikidata properties* is shown in the Appendix E.1.

#### 4.4 Selection of Wikidata Triples

**Definition of a triple.** A *knowledge graph triple* is an ordered triple  $(h, r, t)$ , where  $h$  is the *head entity*,  $r$  is the *relation*, and  $t$  is the *tail entity*.

Mathematically, a *knowledge graph* can be represented as a directed graph  $G = (V, E)$ , where  $V$  is the set of vertices (nodes) representing entities, while  $E$  is the set of edges representing relationships between entities. Each edge  $e \in E$  is an ordered pair  $(h, r, t)$ , where  $h \in V$  is the head entity;  $r \in R$  is the relation, with  $R$  being the set of all possible relations; and  $t \in V$  is the tail entity.

<sup>9</sup>For illustration, consider these two triples inside Wikidata: Fruitopia is *instance-of* drink brand and Fruitopia is *subclass-of* drink. The head entity is Fruitopia, and the tail entity is drink brand/ drink.

<sup>10</sup>Fruitopia’s page in Wikidata <https://www.wikidata.org/wiki/Q263424>

Edge Property	Target Item ID
instance-of	36,906,466
subclass-of	3,695,190

Table 1: Examples of  $G_{Wiki}$  triples defined by *instance-of* and *subclass-of*.

**Wikidata Triples.** Given  $G_{Wiki}$  triples  $\{(h_1, r_1, t_1), \dots, (h_n, r_n, t_n)\}$  where  $h_i$ ,  $r_i$ ,  $t_i$  denote the head entity, relation, and tail entity respectively, we utilize two relations/properties *instance-of* & *subclass-of* to collect triples  $\mathcal{T}_c$  for each topic  $c$ . In KDWD, there are 141M triples similar to those shown in Table 1. We used *instance-of* & *subclass-of* to collect 26M and 1.7M triples, respectively<sup>11</sup>.

#### 4.5 Collection of Wiki-KG Dictionaries

As mentioned in §3, §4.3, and §4.4, we extracted the head entities  $\mathcal{H}_t$  from triples in  $\mathcal{T}$ . The head entities are hyponyms representing entity mentions for each topic, i.e., NE. Next, we created a dictionary for each NE, containing the hyponyms. We deployed these dictionaries to obtain Wikipedia articles and to annotate spans of text using ES. In Table 15, we report the size of dictionaries obtained during dataset curation, for each NE. Examples of dictionary entries for each NE are shown in Table 16. In addition, we describe steps to obtain dictionaries for each entity type in Appendix F.

#### 4.6 Selection of Wikipedia Paragraphs

Whereas it was easier to collect posts from Reddit and Stack Exchange, we followed a more carefully designed process to gather Wikipedia paragraphs.

For each NE, we use the dictionary entries from §4.5, and their unique *Page IDs* to obtain corresponding articles, from a collection of 5.3M articles in English Wikipedia (more in Appendix 4.6). After retrieving the Wikipedia article, we filtered out all other sections to keep only the *introduction* section for that article (we discuss this decision in detail in Appendix H). We gathered all paragraphs in the *introduction* section. Next, we split each paragraph into sentences. The collection of sentences formed the text corpus from which the NER dataset was constructed (see Step 3.2 in Figure 3).

<sup>11</sup>That is to say, P31 exists in many more triples in  $G_{Wiki}$  than P279.

Figure 5: Text-span annotations inside ES (underlined text in figure). Some text-spans were incorrectly annotated (marked inside [ ] symbols above). For example, **Food** mentions were completely missed (i.e., puttu, lapis legit, kastengel, risoles), or a part of the entity mention was left outside the text span (i.e., in kue ku, kue putu). When manually checking the correctness of text-spans annotated with ES, we corrected these spans of text.

Examples of annotated Sentences
Caffè latte <sup>DRINK</sup> often shortened to just latte <sup>DRINK</sup> in English, is a coffee <sup>DRINK</sup> drink of Italian origin made with espresso <sup>DRINK</sup> and steamed milk <sup>DRINK</sup> . Variants include the chocolate-flavored mocha <sup>DRINK</sup> or replacing the coffee <sup>DRINK</sup> with another beverage base such as masala chai <sup>DRINK</sup> (spiced Indian tea), mate <sup>DRINK</sup> , matcha <sup>DRINK</sup> , turmeric <sup>DRINK</sup> or rooibos <sup>DRINK</sup> ; alternatives to milk <sup>DRINK</sup> , such as soy milk <sup>DRINK</sup> or almond milk <sup>DRINK</sup> , are also used.

Table 2: An annotated case from *NERsocial*. The Sentences contain several mentions of DRINK that we annotated.

#### 4.7 Annotation Scheme

We propose an annotation scheme based on ES. Throughout the construction of *NERsocial*, annotation of *entity mentions* within each sentence is guided by the dictionaries gathered in §4.5. We prepared thousands of sentences for annotation by removing any XML&HTML tags, URLs, and non-UTF8 characters. Then, we imported the sentences into ES. Table 2 shows an annotated case from *NERsocial*. ES details are shown in Appendix D.

**Humans verify text-spans.** After annotating spans of text corresponding to *entity mentions* within sentences, we applied human checks to ensure the text-spans were accurate. Moreover, incorrect spans were corrected while missed entity mentions were annotated<sup>12</sup> (illustrated in Figure 5).

Recall that our annotation scheme utilizes dictionary entries gathered from a reputable knowledge source, *GWiki*. Most annotations were correct. Hence, minimal incorrect annotations and

<sup>12</sup>Missed spans only occur when the dictionary does not contain the entry matching that span of text.

	Annotator A&B	Annotator A&C	Annotator B&C
C.Kappa	88.3%	92.9%	90.6%

Table 3: Agreement between pairs of annotators, measured by Cohen’s Kappa.

minimal cost of human verification.

**Text-span to BIO-tag conversion.** We implemented a Python program to assign the appropriate BIO tags to all marked spans of text in each sentence. The pairs of sentence and BIO tags constitute our new NER dataset, dubbed *NERsocial*. Hereafter, *NERsocial* is split into train/dev/test sets to fine-tune a NER model (Step 4 in Figure 3).

## 5 Dataset Analysis

**Diversity.** The 99.4K sentences annotated throughout this process were gathered from three data sources. During annotation, we limit the number of sentences fetched for each entity type to 10K for each textual source, such as Reddit. We limit number of sentences from any Wikipedia page to ten.

**Statistics.** The characteristics of *NERsocial* are shown in Table 4. Overall, there are 153,102 entity tokens, 134,074 entities, and 99,448 sentences for six entity types. We gathered most of the entity information from Stack Exchange. Table 6 shows a comparison between *NERsocial* and common NER datasets: OntoNotes, WikiGold, CoNLL2003, WNUT17, I2B2 and FEW-NERD.

**Data quality.** The inter-annotator agreement (IAA), as measured by Fleiss Kappa, is 90.6% indicating a high degree of consistency. Pair-wise agreement for three annotators, measured by Cohen’s kappa (Cohen, 1960) is shown in Table 3.

**Benefit of diverse data sources.** By extending our

framework to *Reddit* and *StackExchange* texts, we annotated 36.6K sentences and 54.9K sentences from both sources, respectively. The sentence number is much larger than 7.8K sentences from Wikipedia texts. Additionally, the diversity of our dataset is enhanced, as shown in Figure 4.

## 6 Experiments and Results

To measure the effectiveness of our dataset, we fine-tuned NER models to recognize the newly proposed entity types using the training set of *NERsocial* and evaluated the models on the testing set.

### 6.1 Implementation Details

**NER models.** Following common practice in supervised NER, we fine-tuned three pre-trained transformer models available at Hugging Face, by splitting our dataset into training data (80%), validation data (10%), and testing data (10%). These are the NER models used in this work:

**BERT-base** (Devlin et al., 2019). We deploy *bert-base-uncased*<sup>13</sup>, a 110M parameter model.

**RoBERTa-base** (Liu et al., 2019). We adapt *RoBERTa-base*<sup>14</sup> and fine-tune it for NER.

<sup>13</sup><https://huggingface.co/google-bert/bert-base-uncased>

<sup>14</sup><https://huggingface.co/FacebookAI/roberta-base>

**DeBERTa-v3-base** (He et al., 2021). We also utilized *deberta-v3-base*<sup>15</sup> in our experiments.

**Experimental Setup.** All experiments are conducted with one NVIDIA A100 80GB GPU. We split *NERsocial* into train/dev/test sets based on an 8:1:1 ratio. Then, we fine-tuned the BERT-base, RoBERTa-base, and DeBERTa-v3-base using the train set for 10 epochs and reported the performance averaged over three runs. We set the batch size to 64, learning rate to  $1e-05$ , sequence length to 128, and an Adam optimizer. We use three standard NER metrics to evaluate performance: precision, recall, and F1-score.

### 6.2 Results

We observe that BERT-base, RoBERTa-base, and DeBERTa-v3-base achieve competitive results when fine-tuned on *NERsocial*. The average F1-scores are 96.41%, 95.98% and 96.12%, respectively. Overall, models performed best on *pet* and F1-scores are above 98%, while the least F1-scores were obtained on *food*, i.e., 94.29%. The F1-scores for each entity type are shown in Table 7, all of which are above 94%.

A closer look at the three textual sources reveals that NER models fine-tuned on texts from Stack Exchange achieve the highest F1-scores. For instance, the F1-scores for DeBERTa-v3-base after fine-tuning on texts from Wikipedia, Reddit, and Stack Exchange are 83.29%, 95.97%, and 98.07%, respectively, which emphasizes the relevance of texts from interactive platforms (e.g., Reddit and Stack Exchange) in creating *NERsocial*. More ablations in §7.

Lastly, due to *RapidNER*'s efficiency, we created a large NER dataset, *NERsocial*, enabling all the

	ID		OOD	
	NERsocial	WNUT	NERsocial	WNUT
<b>BERT-base</b>	96.41	53.04	2.42	8.9
<b>RoBERTa-base</b>	95.95	60.53	2.20	13.10
<b>DeBERTa-v3-base</b>	96.12	58.90	1.46	13.57

Table 8: F1-scores (%) in cross-dataset evaluation setting.

models to recognize the new entity types with high F1-scores, as mentioned above.

### 6.3 Comparison to *WNUT 2017* Dataset

Entity types in *WNUT* include: *person, location, corporation, product, creative work & group* yet *NERsocial* includes *drinks, foods, hobbies, jobs, pets & sports*. There is some overlap in the entity types between the two datasets, i.e., *product*, a broader category in *WNUT*, may include *drink & food* in *NERsocial*. Similarly, *creative work* in *WNUT* may include *hobby* in *NERsocial*. Whereas the entity types in *WNUT* are more general, *NERsocial* includes a set of highly specific entity types. Texts used to construct *WNUT* originate from Twitter, YouTube, Stack Exchange, and Reddit. Meanwhile, we constructed *NERsocial* from Wikipedia, Stack Exchange, and Reddit texts. *WNUT* contains 5.69K sentences, yet *NERsocial* contains 99.4K sentences.

Due to similar textual sources for the two datasets, we investigated the generalizability and transferability of models fine-tuned on one dataset to the other. *First*, we establish baselines on both

datasets separately. On *WNUT* data, BERT-base, RoBERTa-base, and DeBERTa-v3-base achieve 53.04%, 60.53% and 58.90%, respectively. However, the same models achieve 96.41%, 95.95% and 96.12%, respectively. We observe a huge gap in absolute F1-scores among the baseline results, and all models perform better on *NERsocial* (See Table 8). *Second*, we assess the entity-level performance for all models across specific entity types in both datasets, and all the results are shown in Table 7. Overall, NER models achieve consistently high F1 scores across all entities in *NERsocial*. Conversely, the F1-scores for entities in *WNUT* are much lower, except for *Person* entity type. *Third*, we conduct a cross-dataset evaluation, and the goal is to assess the performance drop or improvement for models fine-tuned on one dataset and evaluated on the other, a further indication for the similarity or difference among the two datasets. The evaluation results indicate that models fine-tuned on *NERsocial* and evaluated on *WNUT* (BERT-base 8.9%, RoBERTa-base 13.10%, and DeBERTa-v3-base 13.57%) perform better than their counterparts, fine-tuned on *WNUT* and evaluated on *NERsocial* (BERT-base 2.42%, RoBERTa-base 2.20%, DeBERTa-v3-base 1.46%). These findings indicate that there is higher transferability from *NERsocial* to *WNUT*; than from *WNUT* to *NERsocial*, to illustrate, 13.57% vs 1.46% for DeBERTa-v3-base. (Also in Table 8).

## 7 Ablation Study

We ablate the textual data used to fine-tune. We fine-tune DeBERTa-v3-base using texts from Wikipedia, social media, and online forums, separately. Then, we examine differences in performance across data sources (see results in Figure 13). Overall, texts from social media and online forums provide the best fine-tuning results for each entity type in *NERsocial*. Moreover, all models benefit from fine-tuning with NER data aggregated from all three textual sources. See detailed ablations in Appendix I, and the comprehensive summary or ablations in Table 18.

## 8 Conclusion

In this paper, we presented *RapidNER*, a novel framework that showcases an effective approach to creating NER datasets at a large scale through the integration of subgraph extraction, diverse text sources, and ES-based annotation. The resulting *NERsocial* dataset provides a comprehensive resource for developing NER systems in human-robot interaction contexts. Our methodology significantly reduces the time and effort needed for dataset construction, highlighting its potential for broader applications in new domains.

### Ethical Considerations

**Misuse and Dual-Use.** There is a possibility for misuse. Given our framework, the ease of creating NER datasets for new domains could be exploited for rogue purposes, such as surveillance, targeted advertising, misinformation, and the like. To ascertain ethical usage of our framework, safeguards and guidelines should be established.

**Transparency and Accountability.** Researchers using this framework need to be transparent about the capabilities and inherent biases present, and be prepared to take responsibility for all applications or algorithms developed from the datasets generated using this framework.

### Limitations

**Representation and Bias.** Our dataset is developed using the content available on Reddit, Stack Exchange, Wikipedia and Wikidata. These platforms inherit demographic and cultural biases emanating from their contributor communities. For that matter, the skewed representation could lead to certain named entities being underrepresented,

especially those from non-Western or marginalized communities. The undesirable consequence might be that applications developed using this dataset could have limited universality and fairness.

**NER vs Entity Linking.** Because NER and entity linking (EL) are often treated as separate tasks, we focused on creating a new dataset containing new named entities. We did not include entity linking, i.e., the disambiguation of those named entities with a knowledge base. Therefore, the EL part will be considered in the future work of this project.

**Quality and Reliability of Sources.** The accuracy and reliability of all textual information varies with the users who create it. Our current framework does not have an in-built mechanism to verify the truthfulness or historical reliability of the data extracted.

**Generalizability.** There is an unlimited number of possible entities of interest, yet our study includes just a small fraction of possible entities. The effectiveness of our framework in creating datasets for entities outside the ones tested is not fully established and requires more comprehensive studies.

**Dynamic Content.** Reddit, Stack Exchange, and Wikipedia are dynamic, with content continually being updated, corrected, and expanded. This could lead to the data drift problem, and inconsistency of datasets generated at different times, affecting the reproducibility of subsequent studies.

**Language and Cultural Bias.** Due to reliance on Reddit, Stack Exchange, Wikipedia and Wikidata, our framework is exposed to these platforms' biases, including under-representation of non-English languages and non-Western perspectives. Such biases can affect the diversity and inclusiveness of the datasets created using our framework.

**Reliance on Elasticsearch.** The heavy reliance on ES may not be accessible to all researchers, limiting the reproducibility of the study. However, by detailing our annotation process, we hope other researchers will easily adapt this method to construct their NER datasets.

### Acknowledgment

This work was done during the development of HARU under the mentorship of Eric Nichols at Honda Research Institute Japan (HRI-JP). We thank him for overseeing the creation of datasets, providing access to compute resources and the robot during Jesse's internship at HRI-JP.

## A Definitions of Entity Types

Our goal is to support the social robot’s ability to interact with humans when the entity types shown in Table 9 occur during interaction; for example, the question “*Do you like Fanta?*” corresponds to the *Drink* entity type.

Below are the definitions of entity types given to the annotators. Annotators were hired based on a minimal understanding of linguistics, and we compensated them at a market rate. All annotators are graduate students, two of whom are male and one is female.

**Drink.** This entity type is used for sequences of words denoting explicit mentions of beverages, soft drinks, alcoholic and non-alcoholic drinks.

**Food.** This entity type is used for sequences of words denoting explicit mentions of food, culinary practices, or eating habits.

**Hobby.** This entity type is used for sequences of words denoting explicit mentions of leisure activities or hobbies.

**Job.** This entity type is used for sequences of words denoting explicit mentions of professions, employment opportunities, or job-related activities.

**Pet.** This entity type is used for sequences of words denoting explicit mentions of animals traditionally kept as pets.

**Sport.** This entity type is used for sequences of words denoting explicit mentions of physical activities recognized as sports, including both team sports and individual physical activities.

Entity Type	Example Question
<b>Drink</b>	“Do you like Fanta?”
<b>Food</b>	“What is your favorite cuisine?”
<b>Hobby</b>	“What do you do in your free time?”
<b>Job</b>	“What do you do for a living?”
<b>Pet</b>	“Do you like pets?”
<b>Sport</b>	“What’s your favorite sport?”

Table 9: Exemplar occurrences of the entity types in human dialogue.

We obtained a diverse collection of textual information for each of the entity types described above. Figure 7 is an LDA visualization showing the thirty most prominent *keywords* from the *drink* texts, and the texts are aggregated from all data sources: Reddit, Stack Exchange, and Wikipedia. Moreover, we

can see the distance between clusters of topics in the *drink* information, and most topics are closely related to each other.

## B Reddit Posts

Tables 10, 11, and 12 contain the collection of *subreddits* from which we collected texts while constructing the dataset. For the *hobby* entity type, we adapted a comprehensive list from [https://www.reddit.com/r/Hobbies/comments/zqwx6c/the\\_hobby\\_master\\_list\\_and\\_their\\_subreddit/](https://www.reddit.com/r/Hobbies/comments/zqwx6c/the_hobby_master_list_and_their_subreddit/) but several channels contained zero discussions. Therefore, we needed to use a much larger collection of channels than for the other entity types.

## C Stack Exchange Posts

We gathered texts from these *sites*: *cooking.stackexchange*, *pets.stackexchange*, *workplace.stackexchange*, *alcohol.stackexchange*, *beer.stackexchange*, *coffee.stackexchange*, *crafts.stackexchange*, *gardening.stackexchange*, *homebrew.stackexchange*, *photo.stackexchange*, *sports.stackexchange*, *fitness.stackexchange*, *bicycles.stackexchange*. The above list of *sites* was sufficient to generate a massive corpus ready for annotation.

## D Annotation Scheme based on Elasticsearch

With Elasticsearch (ES)<sup>16</sup>, we sped up the annotation process, significantly reducing the burden incurred with manual annotation of sentences. In fact, our ES annotation scheme costs 0.9 milliseconds to annotate one sentence, yet a manual annotation method, such as the use of *Doccano* costs 1 minute per sentence. This results in massive savings of time and labor costs during annotation.

**Import data into ES.** Thousands of sentences saved inside a CSV file were imported into ES. For each file uploaded to ES, an index is created in ES. It is vital to create an appropriate mapping for the data while uploading it to ES. We needed to use dynamic mapping which supports a fast vector highlighter (fvh). By selecting the Advanced option at data import, we customized the mappings for the columns in the data. An example of such a mapping for the data containing **Food** sentences is shown below:

```
{
  "properties": {
    "column1": { "type": "long" },
    "column2": { "type": "text",
      "term_vector": "with_positions_offsets" }
  }
}
```

In this mapping, *column1* is of type *long* and it contains the unique ID for a sentence. However, *column2* is of type *text*, and it contains the actual sentences to be annotated. To apply the fast vector highlighter to *column2*, we set the argument *term\_vector* to *with\_positions\_offsets*.

**Fast vector highlighter (fvh).** ES constitutes a unique feature called fast vector highlighter or fvh. This is a special highlighter in ES. The fvh highlighter behavior is enabled by setting "term\_vector": "with\_positions\_offsets" on the appropriate column of the data (in this case, *column 2*). The fvh highlighter makes sure that at the time of sentence retrieval, compound terms for example, *Barton Premium Blend*, are not split into their constituent words *Barton*, *Premium*, and *Blend*. The fvh highlighter made it possible to achieve perfect string matching.

**ES Search Space.** Given a NE, we defined the search space for ES as the *dictionary* terms obtained from Wiki-KG for that NE. These terms enabled ES to search, and retrieve sentences in which one, two or more terms *matched* the search space of ES. In other words, we utilized ES as a search engine to return only relevant sentences. Besides, we can deduce that ES search space corresponds to *entity mentions* for a specific NE.

**Annotation with ES.** We employed the fvh highlighter for annotation in three ways. First, *fvh* ensured that *compound* terms were not split into separate words at search time. This is vital because it allowed us to annotate compound terms accurately. Second, via correct string matching between ES search terms and words in sentences, *fvh* enabled us to demarcate text-spans within each sentence that *matched* with one or more terms within the search space. Third, we employed this feature to introduce special tags `<em>` to indicate such text-spans or *entity mentions* in each sentence. In other words, ES was used for *labeling/annotating* all *entity mentions* in each sentence. ES made it possible to mark text-spans for thousands of sentences at once.

<sup>16</sup>We used Elasticsearch version 8.14.0

## E Knowledge Graph to Domain-specific Sub-graphs

We show the detailed process to collect triples and extract sub-graphs like the one in Figure 8.

### E.1 Wikidata properties

The illustration in Figure 9 introduces main concepts in Wiki-KG. In this figure, the list of **items** and their unique Wiki-KG IDs includes: *Universe (Q1)*, *Life(Q3)*, *Cosmology (Q3695190)*, *Property (Q937228)*, *Being (Q203872)*, *Phenomenon (Q483247)*, *Natural Phenomenon (Q203872)*. The

list of Wiki-KG **properties** includes *instance-of* and *subclass-of*. The **statements** indicate relations between items in Wiki-KG e.g., “*Life (Q3) is subclass-of (P279) a Natural Phenomenon (Q203872)*”. In general the statements, hereafter Wiki-KG triples, are of the form [source item ID, edge property, target item ID]. In this work, we employed only two properties, namely: *instance-of (i.e., P31)* and *subclass-of (i.e., P279)*. Because, (i) the properties define a sufficiently large number of Wiki-KG relations. The relations allowed us to generate large dictionary sizes for each target NE. (ii) We aim to retrieve as many child nodes for each parent node. The parent node is the NE. *subclass-of & instance-of* permitted us to gather such child nodes, as illustrated in Figure 8. Both **properties** are described in Ta-

Table 11: A list of subreddits for **Hobby** used to construct *NERsocial*. Part I.

ble 13. All properties are contained in KDWD’s property.csv file.

## E.2 Items in Wikidata

Table 14 shows definitions of some items in Wikidata. The definitions are precise, helping to distinguish between several items in Wikidata.

## F Collection of Wiki-KG Dictionaries

After filtering out triples, the triples were used to gather dictionaries from Wiki-KG via 5 steps. All the triples are defined by two relations **P31** & **P279**. We selected only those triples in which *Target Item ID* correspond to *Item ID* of the *item* of interest. For all remaining triples, the *Source Item IDs* were extracted. At last, via a *join* operation with *item.csv* we got the *English labels*. This collection of *English labels* formed the dictionary for a NE. These

procedures are detailed below.

In KDWD’s *item.csv* file, there exists 51M items, similar to those shown in Table 14. Each entry has three attributes, i.e., *Item ID*, *English Label*, *English Description*. Dictionaries were obtained as follows. **1)** Given a NE such as **Food**, we searched through the *item.csv* file by setting search condition “*English Label* == *Food*”. This enabled us to get the *Item ID* of **Food** as **2095**. **2)** We filtered through the Wiki-KG triples (which were collected in the previous section), and retained only those triples in which the *Target Item ID* is 2095. **3)** We extracted all the *Source Item ID* in each triple. 1,365 *Source Item ID* were obtained for **P31** triples, while 2,884 *Source Item ID* were obtained for **P279** triples. **4)** All the *Source Item ID* were collected and by matching them with the entries in *item.csv* file, we got the set of *English Label* for all *Source*

Table 12: A list of subreddits for **Hobby** used to construct *NERsocial*. Part II.

Property	Description
instance-of	that class of which this subject is a particular example and member (subject typically an individual member with a proper name label), different from P279
subclass-of	all instances of these items are instances of those items; this item is a class (subset) of that item. Not to be confused with P31 (instance-of).

Table 13: Descriptions of two  $G_{Wiki}$  properties.

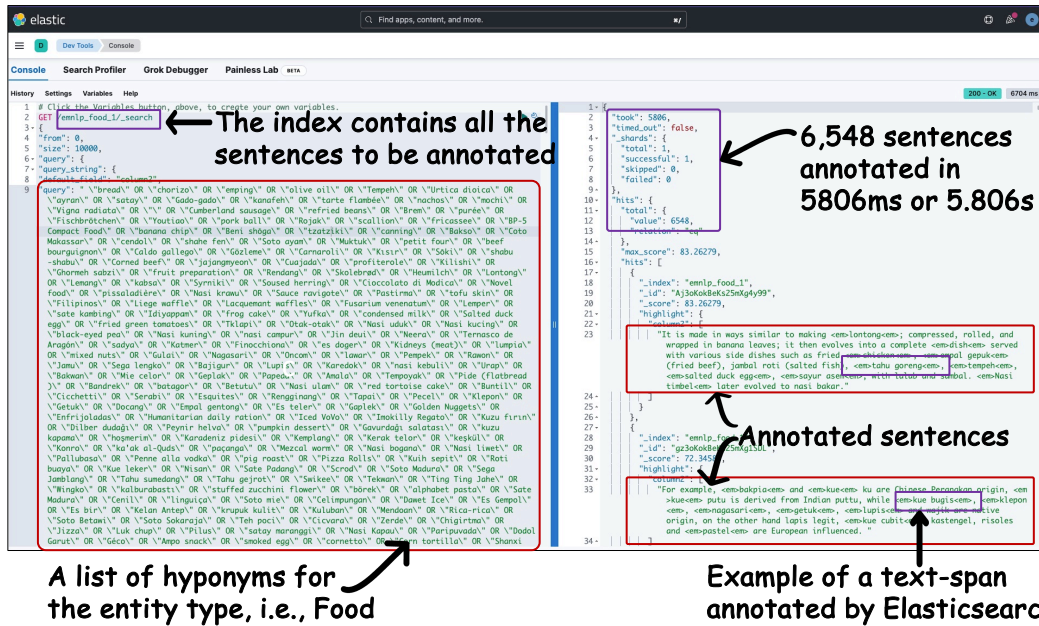

Figure 6: To annotate the texts inside ES, thousands of sentences, and the list of hyponyms are uploaded. We introduced `<em>` tags to make all spans of text that *match* with any entry in the list of hyponyms on the left. We can see annotated spans of text on the right.

Figure 7: The LDA visualization shows the distance between topic-clusters, and the thirty most common terms under the *Drink* entity type in our dataset, among all text sources.

Item ID	Label	Description
1	Universe	totality of space and all contents
2	Earth	third planet from the Sun in the Solar System
5	Human	any member of Homo sapiens, unique extant species of the genus Homo, from embryo to adult

Table 14: Sample of entries in item.csv file of KDWD dataset.

Figure 8: We deploy *instance-of*, and *subclass-of* to extract sub-graphs of each entity type from Wikidata.

Figure 9: Illustration of *items*, *properties*, and *statements* in Wikidata.

*Item ID*. This set formed the dictionary for **Food**. Examples of terms in the dictionary for **Food** are shown in Table 16. 5) We regarded the dictionary obtained for each NE as the set of *entity mentions* for that NE. In short, this dictionary formed the search space/entity mentions for that NE in ES during annotation.

We report the size of dictionaries obtained during dataset curation, for each NE in Table 15. In addition, we describe unique steps used to obtain dictionaries for NE. For these NE: *Drink*, *Food*, *Job*, **P31** and **P279** were sufficient to generate a large number of elements in their dictionaries. Yet, for *Hobby*, *Pet*, *Sport*, we augmented the dictionaries due to a small number of examples obtained from Wiki-KG.

The following describes dictionary augmentation for the NE. **Hobby**: We added more *Hobby* examples from a Wikipedia article<sup>17</sup>. **Job**: Due to *Job* and *Profession* being synonymous with each other, we use the union set of elements contained in the dictionaries of *Job* and *Profession*. **Pet**: The unique term *Pet* returned no dictionary items from

<sup>17</sup>A Wikipedia list of hobbies [https://en.wikipedia.org/wiki/List\\_of\\_hobbies](https://en.wikipedia.org/wiki/List_of_hobbies)

Wikidata so we combined several dictionaries e.g., for *dogs*, *cats*, *horses*, *rodents*, *domesticated birds* to obtain a dictionary size sufficient to guide the annotation process for *Pet*. **Sport**: To ensure no overlap between *Hobby* and *Sport*, all items under *Hobby* identifiable as *Sport* were deleted. Moreover, we couldn't get a significant dictionary size from Wikidata based on **P31** and **P279** so we added more *Sport* examples from a Wikipedia article<sup>18</sup> and one sports website<sup>19</sup>.

Examples of dictionary elements for each NE are shown in Table 16. Furthermore, Table 15 shows the size of each entity type's dictionary.

## G Selecting Wikipedia Paragraphs

Given the *Item ID* for all *Items* in the dictionary of NE such as **Food**, we employ those *Item ID* and obtain the corresponding Wikipedia *Page* for each *Item* as follows.

In KDWD's page.csv file, there exists 5.3M entries in the form shown in Table 17. Each entry has four attributes, i.e., *Page ID*, *Item ID*, *Title*, *Views*. 5.3M entries correspond to the 5.3M articles in English Wikipedia as of November 2019. The collection of *Item ID* obtained from the previous section permitted us to acquire *Page IDs*. Each *Page ID* refers to a unique article within Wikipedia. Hence, we can obtain the Wikipedia page and its contents.

## H Why we filter out other sections of the Wikipedia Article?

We aim to extract the most concise information from Wikipedia. The Wikipedia Manual of Style<sup>20</sup> recommends that “*An article's content should begin with an introductory lead section – a concise summary of the article – which is never divided into sections*”. Hence, by design, the introductions are intended to capture the essence of a Wikipedia article. Moreover, Wikipedia introductions have previously been used as query-relevant summaries or ground truth for evaluating the quality of summaries in information retrieval and text summarization research (Svore et al., 2007). Lastly, we aim for a wider distribution of entities in our

<sup>18</sup>A Wikipedia list of sports [https://en.wikipedia.org/wiki/List\\_of\\_sports](https://en.wikipedia.org/wiki/List_of_sports)

<sup>19</sup>This website lists popular sports <https://trenz1.com/sports/>

<sup>20</sup>URL for the Wikipedia Manual of Style [https://en.wikipedia.org/wiki/Wikipedia:Manual\\_of\\_Style](https://en.wikipedia.org/wiki/Wikipedia:Manual_of_Style).

Named Entity	KG Triple Size		Dictionary Size		#Wikipedia Pages
	(26M) P31	(1.7M) P279	P31/ P279	Total	
<b>Drink</b>	281	309	249 / 280	529	451
<b>Food</b>	1,365	2,884	321 / 2,683	3,004	2,613
<b>Hobby</b>	35	13	28 / 12	40	24
<b>Job/Profession</b>	6,475	82	4,126 / 61	4,187	1,527
<b>Pet</b>	5	10	5 / 10	15	11
<b>Sport</b>	164	120	137 / 103	240	160

Table 15: Size of dictionaries used to construct *RapidNER*, and the number of Wikipedia pages. For NE with few pages gathered, we collected extra pages using authentic lists relevant to such NE in Wikipedia.

Table 16: An overview of dictionaries extracted from Wikidata, for six named entities, **Drink**, **Food**, **Hobby**, **Job**, **Pet**, and **Sport** during the construction of *NERsocial*.

dataset. Hence, we selected the most precise section of the Wikipedia article, and this decision enabled us to collect more texts from millions of other articles. Figure 10 indicates the *title* and *introduction* sections which were paramount during dataset construction.

## I Domain Transfer: Impact of Text-source on NER Performance

Recognizing the need for robust NER models that can generalize well to other domains, we investigated model sensitivity to domain shifts such as

Page ID	Item ID	Title	Views
12	6199	Anarchism	31335
25	38404	Autism	49693

Table 17: Sample of entries in page.csv file of KDWD dataset.

data sampled from different text-sources. We conducted experiments under both in-domain (ID) and out-of-domain (OOD) settings. Our experiments show that combining data from different sources, such as Wikipedia, social media and online forums,

The image shows a screenshot of the Wikipedia article for "Siberian Husky". Several sections are highlighted with red boxes and labels:

- Title:** The word "Siberian Husky" at the top of the article.
- Introduction:** The first paragraph of the article, starting with "This article is about the dog breed. For other uses, see Husky (disambiguation).".
- Page contents:** The left-hand navigation menu containing sections like Lineage, Description, Coat, Eyes, Nose, Tail, Size, Behavior, Health, History, etc.
- Infobox:** The right-hand sidebar containing a photo of a black and white Siberian Husky, its other names (Chukcha), common nicknames (Husky, Sibe), origin (Siberia), and a table of traits including height, weight, coat, color, litter size, and life span.

Other sections like "Lineage" and "Description" are also visible but not explicitly labeled with red boxes in the image.

Figure 10: Illustration of main sections of a Wikipedia article. We are interested in the **title** and **introduction** of the article.

is a promising strategy to make the NER systems less sensitive to domain shifts; due to improved diversity. NER models showed an improved performance.

In this experiment, we fine-tuned three NER models on Wikipedia text, and saved the model. Then, we conducted an OOD evaluation in which each model was initialized with the saved weights after fine-tuning. Results indicate a drop in F1-scores across all domains, for all three models (see Figure 11). The drop in performance indicates the difference in characteristics between text found inside Wikipedia and texts in social media and online forums.

NER Model	Drink			Food			Hobby			Job			Pet			Sport			Avg. (F1)

Table 18: Detailed ablation results for in-domain (ID) and out-of-domain (OOD) experiments for NER models fine-tuned on social media, online forum, and Wikipedia texts. P, R, and F1 stand for precision, recall, and F1-score, respectively.

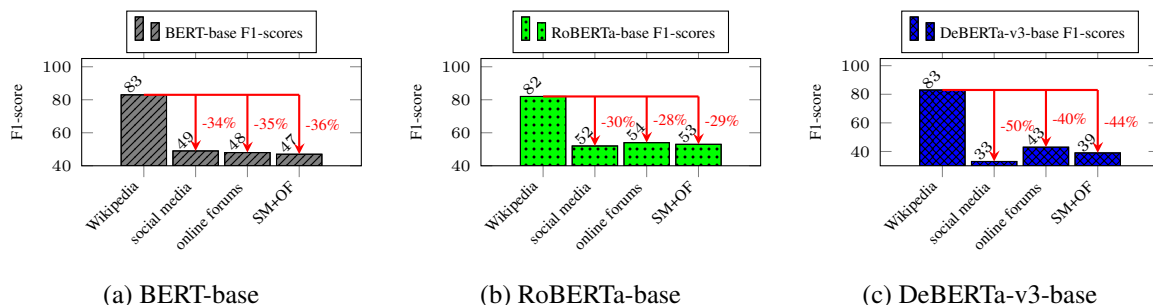

Figure 11: **Domain transfer from Wikipedia to other domains:** F1-scores for different models (BERT-base, RoBERTa-base, DeBERTa-v3-base) when transferred from Wikipedia (in-domain) to other domains: social media (Reddit), online forums (Stack Exchange), and a mix of both. SM stands for social media, while OF stands for online forums. *Performance drops are marked in red.*

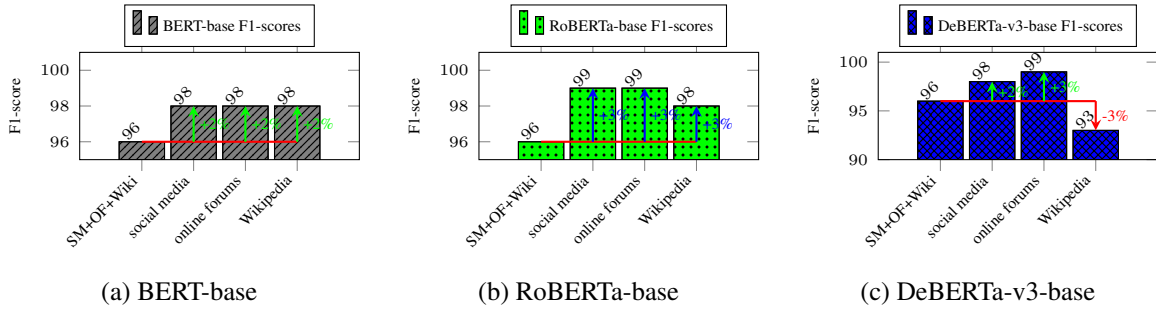

Figure 12: **Combined domain-data boosts performance.** Improved F1-scores for different models (BERT-base, RoBERTa-base, DeBERTa-v3-base) when fine-tuned on all domain data. SM stands for social media, while OF stands for online forums.

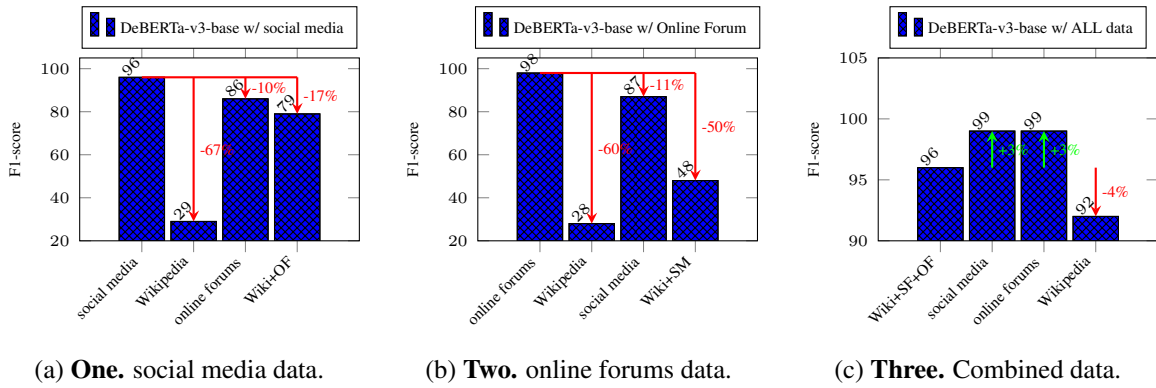

Figure 13: We ablate the source of data (social media, online forums, combined texts) used to fine-tune DeBERTa-v3-base for NER. Then, we conduct OOD experiments to measure the ability of the fine-tuned model to generalize to unseen domains. *DeBERTa-v3-base performance in OOD setting improves when finetuned with a combination of all data sources; see (c) on the right.* SM stands for social media, while OF stands for online forums.

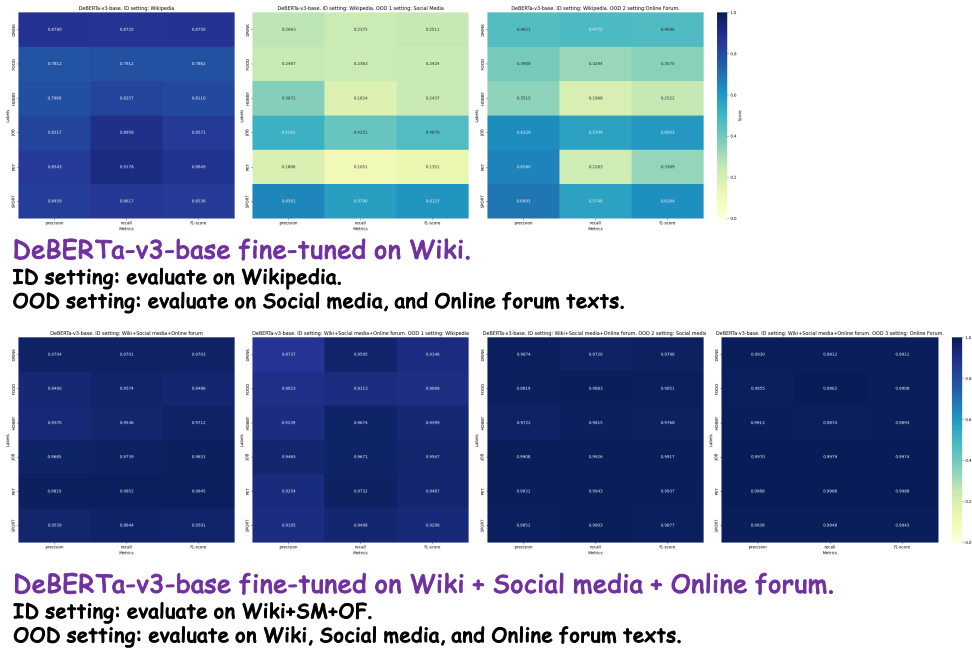

Figure 14: Heatmaps showing the Precision, Recall, and F1-score across named entities; for both ID and OOD settings. The NER model is DeBERTa-v3-base.

**BERT-base fine-tuned on Wiki.**

**ID setting:** evaluate on Wiki.

**OOD setting:** evaluate on Social media, and Online forum texts.

**BERT-base fine-tuned on Wiki + Social media + Online forum.**

**ID setting:** evaluate on Wiki+SM+OF texts.

**OOD setting:** evaluate on Wiki, Social media, and Online forum texts.

Figure 15: Heatmaps showing the Precision, Recall, and F1-score across named entities; for both ID and OOD settings. The NER model is BERTa-base.

**RoBERTa-base fine-tuned on Wiki.**

**ID setting:** evaluate on Wiki.

**OOD setting:** evaluate on Social media, and Online forum texts.

**RoBERTa-base fine-tuned on Wiki + Social media + Online forum.**

**ID setting:** evaluate on Wiki+SM+OF texts.

**OOD setting:** evaluate on Wiki, Social media, and Online forum texts.

Figure 16: Heatmaps showing the Precision, Recall, and F1-score across named entities; for both ID and OOD settings. The NER model is RoBERTa-base.
