

Bridging Vision and Language: Modeling Causality and Temporality in Video Narratives

Ji-jun Park, Soo-joon Choi
Dongguk University

Abstract—Video captioning is a critical task in the field of multimodal machine learning, aiming to generate descriptive and coherent textual narratives for video content. While large vision-language models (LVLMs) have shown significant progress, they often struggle to capture the causal and temporal dynamics inherent in complex video sequences. To address this limitation, we propose an enhanced framework that integrates a Causal-Temporal Reasoning Module (CTRM) into state-of-the-art LVLMs. CTRM comprises two key components: the Causal Dynamics Encoder (CDE) and the Temporal Relational Learner (TRL), which collectively encode causal dependencies and temporal consistency from video frames. We further design a multi-stage learning strategy to optimize the model, combining pre-training on large-scale video-text datasets, fine-tuning on causally annotated data, and contrastive alignment for better embedding coherence. Experimental results on standard benchmarks such as MSVD and MSR-VTT demonstrate that our method outperforms existing approaches in both automatic metrics (CIDEr, BLEU-4, ROUGE-L) and human evaluations, achieving more fluent, coherent, and relevant captions. These results validate the effectiveness of our approach in generating captions with enriched causal-temporal narratives.

Index Terms—Video Narratives, Vision and Language, Large Vision-Language Models

I. INTRODUCTION

Video captioning has become a pivotal task in multimodal machine learning, enabling systems to generate natural language descriptions of video content. Recent advancements in large vision-language models (LVLMs) have showcased impressive capabilities in aligning visual and textual modalities, leading to significant progress in video captioning tasks [1]–[3]. However, a critical limitation remains: these models often fail to capture the causal and temporal narratives inherent in complex video sequences. This deficiency hampers their effectiveness in applications requiring a deep understanding of event sequences and their interrelations, such as instructional videos, surveillance analysis, and storytelling [4].

The primary challenges contributing to this shortcoming are twofold. First, existing LVLM architectures lack explicit mechanisms to model causal and temporal dependencies between events. Second, there is a scarcity of annotated datasets that explicitly encode these relationships, limiting the models’ ability to learn and generalize such narratives effectively. Consequently, the captions generated by these models tend to be descriptive yet fail to convey the underlying causal and temporal dynamics, resulting in narratives that are often fragmented or contextually inaccurate [1].

To address these challenges, we propose a novel approach that augments LVLMs with a **Causal-Temporal Reasoning**

Module (CTRM). This module is designed to explicitly model the causal and temporal relationships between events within a video. By integrating CTRM into a state-of-the-art LVLM backbone, such as Flamingo or BLIP-2, we enable the model to generate captions that are not only descriptively accurate but also narratively coherent. Our training framework involves a multi-stage process: (1) pre-training the LVLM on a diverse set of video-text pairs to capture general visual-linguistic patterns, (2) fine-tuning the model on a curated dataset enriched with causal-temporal annotations to instill a deeper understanding of event interrelations, and (3) employing a contrastive loss function to align the learned causal and temporal representations between video frames and their corresponding textual descriptions.

We evaluate the effectiveness of our approach using standard video captioning datasets, such as MSVD and MSR-VTT, as well as a newly curated dataset specifically annotated with causal and temporal narratives. Our evaluation metrics include CIDEr, BLEU-4, and ROUGE-L, which assess the semantic accuracy, fluency, and relevance of the generated captions. Experimental results demonstrate that our method significantly outperforms existing state-of-the-art models across all metrics, particularly in capturing and articulating the causal and temporal aspects of video content.

In summary, our contributions are as follows:

- We introduce a **Causal-Temporal Reasoning Module (CTRM)** that enhances LVLMs’ ability to generate captions with coherent causal and temporal narratives.
- We develop a comprehensive training framework that combines pre-training on general video-text data with fine-tuning on causally and temporally annotated datasets, ensuring the model effectively learns and generalizes these narratives.
- We curate a new dataset with explicit causal-temporal annotations and demonstrate through extensive experiments that our approach achieves superior performance over current state-of-the-art methods in both qualitative and quantitative evaluations.

II. RELATED WORK

A. Large Vision-Language Models

Large vision-language models (LVLMs [5], [6]) have emerged as a prominent paradigm in multimodal learning, bridging visual and textual understanding to solve complex tasks such as video captioning, image-text matching, and

visual question answering. These models leverage the large-scale pre-training paradigm to align visual and linguistic embeddings effectively, leading to substantial improvements across various benchmarks.

Recent studies have explored the architecture and capabilities of LVLMs. Initial works focus on integrating vision and language features through transformer-based architectures, demonstrating the ability to handle tasks like image captioning and object recognition [1], [7]. More advanced LVLMs extend these capabilities to video data by introducing temporal reasoning modules and leveraging large-scale video-text datasets for pre-training [8]–[10]. These approaches have proven particularly effective for video captioning tasks, where understanding causal and temporal relationships between events is crucial.

Fine-tuning strategies have also been a key area of investigation. Methods such as reinforcement learning have been employed to adapt LVLMs for decision-making tasks, enabling these models to solve multi-step, goal-directed challenges [11], [12]. Another line of work highlights the importance of designing evaluation protocols tailored to LVLMs, addressing challenges like redundant visual content and reliance on pre-trained language model biases [7]. These findings have led to the development of more robust evaluation frameworks.

In addition to task-specific adaptations, there has been a push toward building generalist LVLMs capable of solving a wide array of vision-language tasks within a unified framework [8]. These models excel in tasks such as visual question answering, image generation, object localization, and pose estimation [13]. Advances in long-context modeling have further enhanced LVLMs, allowing them to process and generate extended contextual information, which is critical for complex narratives [14], [15].

While these advances have significantly expanded the scope of LVLMs, the challenge of capturing causal and temporal dependencies in video narratives remains underexplored. Our work addresses this gap by introducing a novel framework that explicitly models causal and temporal reasoning, significantly enhancing the performance of LVLMs in video captioning tasks.

B. Video Captioning

Video captioning is a multifaceted task that involves generating coherent textual descriptions for video content, integrating insights from computer vision and natural language processing. Recent advancements have introduced various methodologies to enhance the accuracy and efficiency of video captioning systems.

Traditional approaches often rely on offline processing, where the entire video is analyzed before generating captions. However, this method can be inefficient and may not capture dynamic events effectively. To address these limitations, researchers have proposed online and streaming models that generate captions in real-time as the video progresses. For instance, Zhou et al. introduced a streaming dense video

captioning model that processes incoming video frames sequentially, enabling prompt and temporally localized caption generation [16]. Similarly, Blanco-Fernández et al. proposed a live video captioning framework that anticipates future events to produce timely and contextually relevant captions [17].

Another significant advancement is the incorporation of large-scale pre-trained models to enhance video captioning performance. Ma et al. developed a retrieval-enhanced zero-shot video captioning approach that leverages pre-trained vision and language models to generate captions without requiring extensive task-specific training data [18]. This method utilizes learnable tokens to bridge the gap between visual content and textual descriptions, facilitating effective zero-shot learning.

Efficiency in processing video data has also been a focal point. Shen et al. proposed a compressed video captioning model that operates directly on compressed video streams, reducing computational overhead while maintaining high caption quality [19]. This approach bypasses the need for full video decompression, enabling faster and more resource-efficient caption generation.

Furthermore, the integration of multimodal information has been explored to improve captioning accuracy. Jin et al. introduced a dual-graph and gated fusion model that aggregates appearance and motion features from videos, capturing complex spatio-temporal relationships for more descriptive captions [20]. This method employs graph-based reasoning to model interactions between objects and actions within the video.

In summary, recent research in video captioning has focused on developing models capable of real-time processing, leveraging large-scale pre-trained models for zero-shot learning, enhancing computational efficiency, and integrating multimodal information. These advancements contribute to more accurate, timely, and contextually relevant video captions, broadening the applicability of video captioning systems across various domains.

III. METHOD

In this section, we present the proposed method for enhancing large vision-language models (LVLMs) to generate video captions with coherent causal-temporal narratives. Our approach falls under the category of **generative models**, where the objective is to produce captions that explicitly capture the causal and temporal dependencies within video sequences. The core innovation lies in the integration of a **Causal-Temporal Reasoning Module (CTRM)** into the LVLM framework, which explicitly encodes causal dynamics and temporal relationships to improve narrative coherence.

A. Model Architecture

The overall architecture consists of two key components: (1) a vision-language backbone, which serves as a strong foundation for general video-text understanding, and (2) the proposed CTRM, which encodes causal and temporal dependencies. Given a video sequence $\mathcal{V} = \{v_1, v_2, \dots, v_T\}$, where

v_t represents the features of the t -th frame, the goal is to generate a natural language caption $\mathcal{C} = \{w_1, w_2, \dots, w_N\}$ that accurately reflects the causal and temporal structure of events in the video.

The model estimates the conditional probability of the caption $P(\mathcal{C}|\mathcal{V})$, decomposed autoregressively as:

$$P(\mathcal{C}|\mathcal{V}) = \prod_{i=1}^N P(w_i|w_{<i}, \mathcal{V}), \quad (1)$$

where $w_{<i}$ denotes all words generated up to the i -th step.

B. Causal-Temporal Reasoning Module (CTRM)

The CTRM is composed of two submodules: the **Causal Dynamics Encoder (CDE)** and the **Temporal Relational Learner (TRL)**.

1) *Causal Dynamics Encoder*: The CDE is designed to identify and encode causal relationships between video events. Given frame features \mathcal{V} , the CDE employs a self-attention mechanism to model the causal structure. Specifically, a causal attention matrix \mathbf{A}_c is computed as:

$$\mathbf{A}_c = \text{softmax} \left(\frac{\mathbf{Q}_c \mathbf{K}_c^\top}{\sqrt{d_k}} \right), \quad (2)$$

where $\mathbf{Q}_c, \mathbf{K}_c \in \mathbb{R}^{T \times d_k}$ are the query and key matrices derived from the frame embeddings, and d_k is the embedding dimension. The resulting causal embeddings \mathbf{H}_c are computed as:

$$\mathbf{H}_c = \mathbf{A}_c \mathbf{V}_c, \quad (3)$$

where $\mathbf{V}_c \in \mathbb{R}^{T \times d_k}$ is the value matrix.

2) *Temporal Relational Learner*: The TRL captures temporal dependencies across video frames. Using the causal embeddings \mathbf{H}_c , the TRL applies a transformer-based encoder:

$$\mathbf{H}_t = \text{Transformer}(\mathbf{H}_c + \mathbf{P}), \quad (4)$$

where $\mathbf{P} \in \mathbb{R}^{T \times d_t}$ represents positional encodings to preserve temporal order. The resulting temporal embeddings \mathbf{H}_t serve as the input to the caption decoder.

C. Caption Decoder

The caption decoder is an autoregressive language model that generates captions token by token. At each decoding step i , the decoder computes the probability of the next word w_i as:

$$P(w_i|w_{<i}, \mathbf{H}_t) = \text{softmax}(\mathbf{W}_o \mathbf{h}_i), \quad (5)$$

where \mathbf{h}_i is the hidden state of the decoder at step i , and \mathbf{W}_o is a learnable output projection matrix.

D. Learning Strategy

To train the proposed model, we adopt a three-stage learning strategy: pre-training, fine-tuning, and contrastive alignment.

1) *Pre-training*: The LVLM backbone is pre-trained on large-scale video-text datasets to learn general visual and textual representations. The pre-training loss is the standard cross-entropy loss:

$$\mathcal{L}_{\text{pre}} = - \sum_{i=1}^N \log P(w_i|w_{<i}, \mathcal{V}). \quad (6)$$

2) *Fine-tuning*: The CTRM is fine-tuned on a curated dataset enriched with causal and temporal annotations. To encourage the model to learn causal and temporal dependencies, the fine-tuning loss combines the captioning loss with auxiliary losses:

$$\mathcal{L}_{\text{fine}} = \mathcal{L}_{\text{caption}} + \lambda_1 \mathcal{L}_{\text{causal}} + \lambda_2 \mathcal{L}_{\text{temporal}}, \quad (7)$$

where $\mathcal{L}_{\text{caption}}$ is the cross-entropy loss for caption generation, $\mathcal{L}_{\text{causal}}$ promotes the alignment of causal features, and $\mathcal{L}_{\text{temporal}}$ ensures temporal consistency.

3) *Contrastive Alignment*: To align the causal and temporal embeddings with textual representations, we introduce a contrastive loss:

$$\mathcal{L}_{\text{contrast}} = - \log \frac{\exp(\text{sim}(\mathbf{H}_t, \mathbf{E}_{\text{text}})/\tau)}{\sum_{j=1}^B \exp(\text{sim}(\mathbf{H}_t, \mathbf{E}_{\text{text}}^{(j)})/\tau)}, \quad (8)$$

where $\text{sim}(\cdot, \cdot)$ is a similarity function, \mathbf{E}_{text} represents the textual embedding, τ is a temperature parameter, and B is the batch size.

E. Overall Loss Function

The final loss function is a combination of all the above components:

$$\mathcal{L} = \mathcal{L}_{\text{pre}} + \mathcal{L}_{\text{fine}} + \mathcal{L}_{\text{contrast}}. \quad (9)$$

This comprehensive learning strategy ensures that the model generates captions that are both narratively coherent and semantically accurate.

IV. EXPERIMENTS

In this section, we present a thorough evaluation of our proposed method. We compare our approach against several state-of-the-art models on standard video captioning datasets, including MSVD and MSR-VTT. Furthermore, we conduct ablation studies to assess the contributions of individual components in our model and perform a human evaluation to analyze the subjective quality of generated captions.

A. Experimental Setup

We benchmark our proposed method (**Proposed+**) against the following baseline models:

- **CEN**: Cause-Effect Network designed for causal reasoning in video captioning.
- **GIT**: A transformer-based generative model tailored for video captioning tasks.
- **MARN**: Memory-Augmented Recurrent Network that incorporates contextual features for captioning.
- **Transformer**: A standard transformer adapted for video captioning.

TABLE I
QUANTITATIVE RESULTS ON MSVD AND MSR-VTT DATASETS.

Model	MSVD			MSR-VTT		
	CIDEr	BLEU-4	ROUGE-L	CIDEr	BLEU-4	ROUGE-L
CEN	17.88	45.3	49.2	17.44	42.6	46.8

Transformer	62.8	3.8
Proposed+	75.9	4.5

The evaluation metrics include CIDEr, BLEU-4, and ROUGE-L to measure semantic accuracy, fluency, and relevance. For human evaluation, we assess the captions based on fluency, coherence, and relevance using a five-point Likert scale.

B. Quantitative Results

Table I shows the results of our model compared with baselines. Our method achieves state-of-the-art performance on both datasets, demonstrating the effectiveness of incorporating causal and temporal reasoning.

C. Ablation Study

To assess the importance of each component, we performed ablation studies by removing or modifying key modules in our model. The results, summarized in Table II, highlight the critical role of the Causal Dynamics Encoder (CDE) and Temporal Relational Learner (TRL).

D. Human Evaluation

We also conducted a human evaluation to assess the subjective quality of the generated captions. Annotators rated captions on fluency, coherence, and relevance using a Likert scale from 1 (poor) to 5 (excellent). Table III demonstrates that our method consistently outperformed baselines across all dimensions.

E. Analysis and Discussion

In this subsection, we delve deeper into analyzing the effectiveness of our proposed method (**Proposed+**) from multiple perspectives. We explore its performance in terms of causality understanding, temporal consistency, robustness to diverse video content, and scalability.

1) *Causality Understanding*: One of the central goals of this work is to enhance the model’s ability to understand and generate captions that reflect causal relationships in video narratives. To quantify this, we manually annotated a subset of captions from the MSVD dataset with explicit causal relationships. We measured the ratio of captions that successfully captured the causal connections present in the video content. As shown in Table IV, our method significantly outperforms baselines in capturing causality, demonstrating the effectiveness of the Causal Dynamics Encoder (CDE).

The results indicate that the CDE effectively encodes causal dynamics, enabling the model to generate captions that are logically connected and narratively coherent.

2) *Temporal Consistency*: Temporal consistency is another critical aspect of video captioning, particularly for tasks involving sequential actions or complex event structures. To assess this, we analyzed the generated captions for temporal errors, such as incorrect event order or omission of key events. Table V summarizes the percentage of captions that are temporally consistent.

TABLE VI
ROBUSTNESS ANALYSIS ACROSS VIDEO COMPLEXITY LEVELS.

Model	Simple Scenes	Moderate Scenes	Complex Scenes
CEN	18.2	17.1	16.3
GIT	17.5	16.3	15.2
MARN	15.8	14.5	13.2
Transformer	16.4	15.3	14.7
Proposed+	19.0	18.4	17.6

TABLE VII
SCALABILITY AND COMPUTATIONAL EFFICIENCY.

Model	Training Time (sec/batch)	Inference Time (sec/sample)
CEN	1.32	0.21
GIT	1.27	0.19
MARN	1.45	0.23
Transformer	1.25	0.18
Proposed+	1.35	0.20

The superior performance of our method in temporal consistency is attributed to the Temporal Relational Learner (TRL), which effectively captures sequential dependencies in video frames.

3) *Robustness to Diverse Video Content*: To evaluate the robustness of our method, we tested it across videos with varying levels of complexity, including action-packed sequences, dialogues, and abstract scenes. We grouped videos into three categories based on complexity and analyzed the CIDEr scores for each category. The results, shown in Table VI, indicate that our method maintains strong performance across all types, particularly excelling in complex scenes where causal and temporal reasoning is critical.

4) *Scalability and Computational Efficiency*: To ensure the scalability of our method, we analyzed its computational requirements during both training and inference. Despite the additional modules (CDE and TRL), the overall increase in computational overhead was minimal due to the efficient integration of these components. Table VII compares the training and inference time per batch across models.

The results demonstrate that our method achieves superior performance with only a marginal increase in computational cost, making it both effective and efficient.

V. CONCLUSION

In this paper, we have addressed a key limitation in video captioning: the inability of existing models to effectively capture and articulate causal and temporal narratives. By introducing the Causal-Temporal Reasoning Module (CTRM), we enable large vision-language models to generate captions that are not only descriptive but also narratively coherent. The CTRM, composed of the Causal Dynamics Encoder (CDE) and Temporal Relational Learner (TRL), significantly improves the model’s ability to encode and reason about causal dependencies and sequential event structures. Extensive experiments on standard datasets, supported by ablation studies and human evaluations, demonstrate that our method

achieves state-of-the-art performance in both qualitative and quantitative analyses. Additionally, we show that our approach is robust across diverse video content and computationally efficient, making it practical for real-world applications. Moving forward, we envision further extending this work to multi-lingual video captioning and domain-specific scenarios, such as instructional and medical videos, where causal and temporal understanding is paramount.
