Reliably Learn to Trim Multiparametric Quadratic Programs via Constraint Removal

Zhinan Hou, Keyou You

Abstract—In a wide range of applications, we are required to rapidly solve a sequence of convex multiparametric quadratic programs (mp-QPs) on resource-limited hardwares. This is a nontrivial task and has been an active topic for decades in control and optimization communities. Observe that the main computational cost of existing solution algorithms lies in addressing many linear inequality constraints, though their majority are redundant and removing them will not change the optimal solution. This work learns from the results of previously solved mp-QP(s), based on which we propose novel methods to reliably trim (unsolved) mp-QPs via constraint removal, and the trimmed mp-QPs can be much cheaper to solve. Then, we extend to trim mp-QPs of model predictive control (MPC) whose parameter vectors are sampled from linear systems. Importantly, both online and offline solved mp-QPs can be utilized to adaptively trim mp-QPs in the closedloop system. We show that the number of linear inequalities in the trimmed mp-QP of MPC decreases to zero in a finite timestep, which also can be reduced by increasing offline computation. Finally, simulations are performed to demonstrate the efficiency of our trimming method in removing redundant constraints.

Index Terms—Multiparametric quadratic program, linear inequality, constraint removal, model predictive control, performance analysis.

I. INTRODUCTION

This work focuses on the multiparametric quadratic program (mp-QP) with a convex quadratic cost function and many linear inequality constraints where the linear term of the cost function and right-hand side of the constraints depend on a vector of parameters that may change from one step to another. It has emerged in a huge variety of applications in control [\[1\]](#page-12-0), [\[2\]](#page-12-1), operations research [\[3\]](#page-13-0), machine learning [\[4\]](#page-13-1) and many others, which require rapidly solving mp-QP over resourcelimited hardwares.

By exploiting the unique structure of mp-QP, quite a few innovative methods have been proposed in the literature. They can be roughly categorized as active-set [\[5\]](#page-13-2), interiorpoint [\[6\]](#page-13-3), first-order [\[7\]](#page-13-4), and nonnegative least squares [\[8\]](#page-13-5) methods. As a first-order method, the alternating direction method of multipliers (ADMM) [\[9\]](#page-13-6) is core to the prominently featured solvers – OSQP [\[10\]](#page-13-7) and TinyMPC [\[11\]](#page-13-8), which is developed for application of the embedded model predictive control (MPC). All these methods consume a large portion of computational resources in handling inequality constraints. In particular, the complexity of an active-set method grows exponentially with the number of constraints [\[12\]](#page-13-9). However, the majority of inequality constraints in mp-QP turn out to be redundant in the sense that removing them will not change the optimal solution. To the contrary, if the mp-QP has no inequality constraint, the optimal solution simply takes a linear form of the parameter vector and moreover, the gain remains constant over the space of parameter vector. In fact, the less the number of inequality constraints in mp-QP, the faster these solution methods converge. This motivates us to trim an unsolved mp-QP via removing redundant inequalities, after which we only need to solve a "slim" mp-QP, hoping to accelerate the above-mentioned solution methods.

Then, a natural question is how to cheaply and rapidly trim mp-QP, *as slim as possible*? Noting that the minimizer of mp-QP is Lipschitz continuous in parameter vectors [\[13,](#page-13-10) Proposition 7.13], a solved mp-QP can be potentially exploited to accelerate the unsolved one, especially when their parameter vectors are close. This observation forms the basis of warm start in the vast body of literature [\[10\]](#page-13-7). However, it usually requires sophisticated design and many solution methods, e.g., inter-point methods, are difficult to warm start. Thus, it is mostly used in practice and usually lacks theoretical guarantee.

Quite differently, we utilize the results of a solved mp-QP to remove redundant inequalities of the unsolved mp-QP. More importantly, we propose a novel method to check the redundancy, which at most involves twice of scalar number comparisons per inequality constraint. Clearly, such a simple method can be efficiently implemented on resource-limited hardwares, which is essential to the design of microcontrollers. In addition, we quantify the importance of the solved mp-QP in removing redundant constraints. Specifically, we evaluate the closeness of the two mp-QPs via classifying the distance of their parameter vectors against a sequence of positive numbers, which are the optimal values of mixed integer linear programs (MILPs). Since MILPs do not depend on the parameter vector of mp-QP, they can be solved in prior and offline in the context of MPC. Under the so-called linear independence constraint qualification (LICQ) [\[14\]](#page-13-11), we prove that if their parameter distance is less than the above-mentioned positive number, then the number of linear inequalities remaining in the trimmed mp-QP can be explicitly upper bounded. It is worth mentioning that this number can be very conservative and the empirical results are confirmed much better than the theory dictated. Moreover, we use our trimming method to learn *multiple* solved mp-QPs and establish a "the more the less" result, i.e., the more the solved mp-QPs learnt, the less the inequality constraints in the trimmed mp-QP.

Then, we extend to *adaptively* trim mp-QPs of MPC [\[13,](#page-13-10) Chapter 2] in the online closed-loop system where the parameter vectors are encountered system state vectors. Since MPC is usually used to synthesize control law for constrained systems, the parameter vectors may converge to the origin under standard design choices. We leverage this result to achieve that after a quantified finite timestep, the trimmed mp-QPs have no constraint. Thereafter, the resultant MPC law simply takes a linear form with a fixed control gain.

Noticeably, our method also allows to jointly learn *offline* solved mp-QPs to trim mp-QPs of MPC. Overall, we can not only remove redundant inequalities by learning from the previously solved mp-QPs in the closed-loop system but also those in the offline design. Thus, the trimmed MPC is typically slim with a moderate number of inequality constraints, and we provide a computational tradeoff between the explicit MPC [\[15\]](#page-13-12) and the conventional implicit MPC that yields a control action for each encountered state vector. To elaborate it, the control law of the explicit MPC is offline obtained from solving mp-QP and implemented online via a table-lookup method, while the control action of the implicit MPC is online iteratively computed from mp-QP. Neither of them can benefit from the results of offline and online solved mp-QPs. In comparison, our trimmed MPC can easily take advantages of both solved mp-QPs, and achieve a freedom between offline and online computation of mp-QPs.

It is worth stressing that constraint removal is not a new technique to accelerate optimization problems, see e.g. [\[16\]](#page-13-13)– [\[19\]](#page-13-14), and recently has been developed to accelerate mp-QPs of MPC via a system-theoretic approach [\[20\]](#page-13-15)–[\[22\]](#page-13-16), where they heavily exploit system properties, such as region of activity [\[20\]](#page-13-15), reachability [\[22\]](#page-13-16), and contractility of the cost function [\[21\]](#page-13-17), to achieve constraint removal. Thus, their methods are limited to mp-QPs of MPC for linear dynamical systems. Differently, we exploit previously solved mp-QPs via a learning-theoretic approach, leading to some salient features: (a) our method can be easily applied to remove redundant constraints of mp-QPs whose parameter vectors are *arbitrarily* generated. (b) The number of removed redundant constraints can be quantified. In particular, when applied to trim mp-QPs of MPC in the linear closed-loop system, the number of linear inequalities is proved to decrease to zero, which is not the case for the system-theoretic approach in [\[20\]](#page-13-15)– [\[22\]](#page-13-16). In fact, they are unable to achieve any guarantee and can only illustrate this phenomenon via simulation. Moreover, simulation results demonstrate that our method is much more efficient in removing redundant inequality constraints.

On the other hand, research on approximate MPC schemes has received resurgent interest recently, see e.g., [\[23\]](#page-13-18)–[\[31\]](#page-13-19). In essence, they first treat the MPC law as a black-box function, albeit piece-wise linear for linear quadratic MPC, and adopt supervised learning to obtain an explicit approximation, which is usually parameterized via a ReLU neural network (NN). Then, they offline solve a large number of randomized mp-QPs of MPC to produce training samples, and online adopt the trained NN to control systems [\[24\]](#page-13-20)–[\[27\]](#page-13-21) or warm start optimization algorithms [\[28\]](#page-13-22). Though stability verification of the system with a ReLU NN in the feedback loop can be achieved via MILP [\[26\]](#page-13-23), [\[27\]](#page-13-21) or semidefinite programming (SDP) [\[32\]](#page-13-24) frameworks, how to obtain a reliable NN remains challenging. For example, the sample complexity of training NNs for stabilization is not clear. In addition, the advantages of using NNs for warm start can only be illustrated via simulation and lack theoretical guarantees [\[28\]](#page-13-22). In comparison, we learn from any finite number of solved mp-QPs to remove redundant inequality constraints and provide rigorous results to evaluate its efficiency.

The rest of paper is organized as follows. In Section [II,](#page-1-0) we introduce the convex mp-QP and our objective. In Section [III,](#page-2-0) we reliably learn from the solved mp-QP(s) to trim unsolved mp-QP via removing redundant inequality constraints. In Section [IV,](#page-5-0) we provide an explicit formula to compute the global Lipschitz constant of mp-QP and evaluate the performance of our trimming method. In Section [V,](#page-6-0) we extend to trim mp-QP of linear MPC. Numerical results are included in Section [VI](#page-8-0) and we draw some conclusion remarks in Section [VII.](#page-9-0)

Notation. Let $\mathbb{N}_{[a,b]}$ be the set of integers lying in the interval [a, b], i.e., $\mathbb{N}_{[a,b]} = \{n \in \mathbb{N} \mid a \leq n \leq b\}$. Given a matrix $A \in \mathbb{R}^{m \times n}$, let A_j denote its j-th row and so is the vector. We say that S is a set-valued mapping from X to Y , denoted by $S: X \rightrightarrows Y$, if for every $x \in X$, $S(x) \subseteq Y$. For a vector (matrix) X , we denote its 2-norm (spectral norm) by $||X||$. Let $B(q, r)$ be a ball centered at $q \in \mathbb{R}^n$ with a radius $r > 0$, i.e., $\mathcal{B}(q,r) = \{v \in \mathcal{R}^n \mid ||v-q|| \leq r\}$. If every element of X is positive, we simply write $X > 0$. For a real number x, the ceiling function $\lceil x \rceil$ returns the smallest integer greater than or equal to x . For two sets A and B , we define $A - B = \{x \mid x \in A, x \notin B\}.$

II. PROBLEM FORMULATION AND OUR OBJECTIVE

In this section, we first introduce the convex multiparametric quadratic program (mp-QP). Then, we outline the objective of learning from solved mp-QP(s) to trim (unsolved) mp-QPs via removing their redundant inequality constraints, after which the trimmed version can be much cheaper to solve.

A. The convex multiparametric quadratic program (mp-QP)

In this work, we focus on the following mp-QP

$$
mp-QP(x): \min_{z} V(z) := \frac{1}{2} z^T H z + x^T F z,
$$
 (1a)

$$
\text{s.t. } z \in \mathcal{Z}(x) := \{ z \in \mathcal{R}^{n_z} | \ Gz \leq Sx + w \}, \tag{1b}
$$

where $x \in \mathbb{R}^{n_x}$ is the parameter vector and $z \in \mathbb{R}^{n_z}$ is the decision vector. The objective function is defined by a positive definite matrix $H \in \mathbb{R}^{n_z \times n_z}$ and $F \in \mathbb{R}^{n_x \times n_z}$ in a quadratic form, and the feasible set $\mathcal{Z}(x)$ is specified by constant $G \in \mathbb{R}^{n_c \times n_z}$, $w \in \mathbb{R}^{n_c}$ and $S \in \mathbb{R}^{n_c \times n_x}$ in a linear form. Throughout this work, $\mathcal{Z}(x)$ is a non-empty set.

With limited computational resources, many applications, e.g., moving horizon control (a.k.a. MPC) and estimation [\[1\]](#page-12-0), [\[2\]](#page-12-1), [\[13\]](#page-13-10), require to rapidly solve mp-QPs with a *sequence* of parameter vectors that are encountered one by one. Such a challenging problem has attracted significant interest for decades in both control and optimization communities. Till now, many innovative methods have been proposed, e.g., [\[5\]](#page-13-2)– [\[8\]](#page-13-5), [\[10\]](#page-13-7), [\[11\]](#page-13-8), all of which uniquely exploit the structure of mp-QP to accelerate solution process, and have achieved tremendous successes in many applications [\[33\]](#page-13-25), [\[34\]](#page-13-26).

Notice that all the aforementioned methods take most computational resources to handle massive inequality constraints in mp-QP of [\(1\)](#page-1-1), though many of them turn out to be redundant in the sense that their removal will not change the optimal solution. Overall, they can be significantly accelerated if redundant inequalities are removed from the feasible set $\mathcal{Z}(x)$. Such an idea has been rarely exploited and motivates the study of trimming mp-QPs of this work.

B. The objective of this work

Since the difference between two mp-QPs in the form of [\(1\)](#page-1-1) lies in their parameter vectors, the result of one solved mp-QP can be potentially used to accelerate the other one. A naive and common idea is to use the solved one to *warm-start* the iteration process of the other, hoping to reduce the iteration number of optimization algorithms. Though empirically appreciated, it generically lacks theoretical guarantee and from the worst-case point of view, it does not help at all.

This work takes a quite different perspective to utilize the results of solved mp-OP(s). Notice that if $\mathcal{Z}(x)$ of the mp-QP contains a large number of linear inequalities, which is the indeed case in many applications, the majority of them are generically redundant. Removing them clearly results in a "slim" mp-QP problem which, more importantly, could be much cheaper to solve. For example, the optimal solution of the mp-QP in [\(1\)](#page-1-1) can be explicitly expressed as $z^*(x)$ = $-H^{-1}F^{T}x$ if there is no linear inequality constraint. Then, a follow-up problem is how to cheaply and reliably remove redundant linear inequalities in $\mathcal{Z}(x)$ *as many as possible*?

In this work, we propose a novel method to reliably learn from the results of solved mp- $QP(s)$ in the form of [\(1\)](#page-1-1) to trim mp-QPs with new parameter vectors via safe constraint removal. It is worth stressing that though the trimmed mp-QP of this work can be made very slim, it has the same optimal solution as the origin one. Moreover, we extend to solve the linear quadratic MPC [\[13,](#page-13-10) Chapter 7] in the form of mp-QP.

III. RELIABLY LEARN TO TRIM MP-QPS VIA SAFE CONSTRAINT REMOVAL

In this section, we learn from the results of solved mp-QPs to trim (unsolved) mp-QP via safe constraint removal, which does not incur any optimality gap and the trimmed mp-QP reserves the optimal solution of the origin mp-QP. First, we introduce a general rule on the optimality of the trimmed mp-QP. Then, we use the results of solved mp-QPs to explicitly design an efficient inequality removal rule by leveraging the Lipschitz continuity of the minimizer of the mp-QP.

A. The trimmed mp-QP

To formalize our idea, we consider the following trimmed version of [\(1\)](#page-1-1)

$$
\min_{z} \frac{1}{2} z^T H z + x^T F z,\tag{2a}
$$

$$
\text{s.t. } z \in \mathcal{Z}(x, \mathbb{I}(x)) = \bigcap_{j \in \mathbb{I}(x)} \mathcal{Z}_j(x), \tag{2b}
$$

where $\mathcal{Z}_j(x) := \{ z \in \mathbb{R}^{n_z} \mid G_j z \leq S_j x + w_j \}$ and \mathbb{I} : $\mathcal{R}^{n_x} \rightrightarrows \mathbb{N}_{[1,n_c]}$ is a set-valued mapping from the parameter vector space to the index set of linear inequalities remaining in the trimmed mp-QP.

Clearly, the larger the index set $\mathbb{I}(x)$, the higher the computational cost required to solve the trimmed mp-QP of [\(2\)](#page-2-1). However, a small set $\mathbb{I}(x)$ may potentially incur optimality gap. In fact, $\mathbb{I}(x)$ plays an important role in balancing the computational cost and optimality of the trimmed mp-QP. Intuitively, the direct design of $\mathbb{I}(x)$ in [\(2b\)](#page-2-2) requires to *solve* the trimmed mp-QP of [\(2\)](#page-2-1) and then check its feasibility of [\(1\)](#page-1-1). If not, we should increase the size of $\mathbb{I}(x)$ and resolve the resultant mp-QP until finding the optimal solution of [\(1\)](#page-1-1). Such a trial-and-error process is computationally demanding and not acceptable. Instead, we adopt a general rule from [\[22\]](#page-13-16) to certify the optimality of the trimmed mp-QP.

B. On the zero optimality gap of the trimmed mp-QP

First, we notice that H is positive definite and the two constraint sets of [\(1b\)](#page-1-2) and [\(2b\)](#page-2-2) are specified by linear inequalities. This implies that the two versions of mp-QPs of [\(1\)](#page-1-1) and [\(2\)](#page-2-1) have unique optimal solutions, which are denoted by $z^*(x)$ and $z^*(x, \mathbb{I}(x))$, respectively. Then, we introduce an auxiliary set $\mathcal{M}(x)$ based on which an optimal condition is adopted to ensure the optimality of the trimmed mp-QP.

Lemma 1: ([\[22,](#page-13-16) Lemma 2]) Let the set-valued mapping $\mathbb{C}: \mathcal{R}^{n_x} \rightrightarrows \mathbb{N}_{[1,n_x]}$ denote the index set of removed inequality constraints, i.e., $\mathbb{C}(x) = \mathbb{N}_{[1,n_c]} - \mathbb{I}(x)$. If there exists a mapping $\mathcal{M} : \mathbb{R}^{n_x} \rightrightarrows \mathbb{R}^{n_z}$ such that for all $x \in \mathbb{R}^{n_x}$,

$$
z^*(x, \mathbb{I}(x)) \in \mathcal{M}(x), \tag{3a}
$$

$$
\mathcal{M}(x) \subseteq \mathcal{Z}(x, \mathbb{C}(x)),\tag{3b}
$$

the trimmed mp-QP in [\(2\)](#page-2-1) does not change the optimal solution, i.e., $z^*(x, \mathbb{I}(x)) = z^*(x)$.

To make it self-contained, we outline the proof of Lemma [1](#page-2-3) here. In view of [\(3\)](#page-2-4), it is trivial that $z^*(x, \mathbb{I}(x)) \in$ $\mathcal{Z}(x,\mathbb{C}(x))$. Since $z^*(x,\mathbb{I}(x)) \in \mathcal{Z}(x,\mathbb{I}(x))$, it follows that $z^*(x,\mathbb{I}(x)) \in \mathcal{Z}(x,\mathbb{I}(x)) \bigcap \mathcal{Z}(x,\mathbb{C}(x)) = \mathcal{Z}(x)$. This implies that $z^*(x, \mathbb{I}(x))$ is also an optimal solution of the mp-QP in [\(1\)](#page-1-1), and thus $z^*(x, \mathbb{I}(x)) = z^*(x)$ as the optimal solution is unique.

In comparison, the joint design of a good pair of $\mathbb{I}(x)$ and $\mathcal{M}(x)$ is relatively easy, as we only need to *enclose* the optimal solution of [\(2\)](#page-2-1) (cf. [\(3a\)](#page-2-5)) which can be achieved without solving the trimmed mp-QP. In fact, Ref. [\[22\]](#page-13-16) leverages this idea and find an $\mathcal{M}(x)$ of [\(3\)](#page-2-4) by exploiting properties of the closedloop dynamical system in the context of linear quadratic MPC. Clearly, such a system-theoretic approach only works for the situation that the parameter vectors are sequentially

Fig. 1. An illustration of Lemma [1.](#page-2-3) The black dashed lines denote isolines of the cost function. The orange region is $\mathcal{M}(x)$, and the green solid and dashed lines represent the planes that are specified by the linear inequalities of $\mathbb{I}(x)$ and $\mathbb{C}(x)$, respectively. The left half-space of the green dashed line is the set $\mathcal{Z}(x,\mathbb{C}(x))$.

generated from a stable linear time-invariant (LTI) system. More importantly, the advantage of their method cannot be theoretically evaluated and only illustrated via simulation. In a sharp contrast, our approach of this work not only apply to *any* sequence of parameter vectors, but its performance can also be explicitly evaluated.

C. Novel methods to reliably trim mp-QPs from a solved one

In this subsection, we show how to utilize a solved mp- $QP(\hat{x})$ to reliably remove redundant linear inequalities in the feasible set of [\(1\)](#page-1-1). Specifically, we use the optimal solution $z^*(\hat{x})$ and active set $\mathbb{A}(\hat{x})$ of the solved mp-QP(\hat{x}) where

$$
\mathbb{A}(\hat{x}) := \{ j \in \mathbb{N}_{[1,n_c]} \mid G_j z^*(\hat{x}) = w_j + S_j \hat{x} \}
$$
 (4)

to explicitly construct a good pair of $\mathbb{I}(x)$ and $\mathcal{M}(x)$ of [\(3\)](#page-2-4).

In view of [\[13,](#page-13-10) Proposition 7.13], the minimizer $z^*(x)$ is Lipschitz continuous on bounded sets, implying that $z^*(x)$ can be enclosed by a ball centered at $z^*(\hat{x})$ with a radius that is
proportional to the distance $\|\hat{x} - x\|$ of the two parameter proportional to the distance $\|\hat{x} - x\|$ of the two parameter vectors, which is the key to the design of $\mathbb{I}(x)$ and $\mathcal{M}(x)$ of [\(3a\)](#page-2-5). To make it precise, we introduce the concept of global Lipschitz constant for the mp-QP.

Definition 1 (Global Lipschitz constant (GLC)): We say that $\kappa \in \mathcal{R}$ is a GLC of the mp-QP of [\(1\)](#page-1-1) if for any $x_1, x_2 \in \mathcal{R}^{n_x}$ and $\forall \mathbb{I} \subseteq \mathbb{N}_{[1,n_c]}$, it holds that

$$
||z^*(x_1, \mathbb{I}) - z^*(x_2, \mathbb{I})|| \le \kappa ||x_1 - x_2||. \tag{5}
$$

Remark 1: Given a fixed $\mathbb{I} \subseteq \mathbb{N}_{[1,n_c]}$, it follows from [\[13,](#page-13-10) Proposition 7.13] that there exists $\kappa_{\mathbb{I}} > 0$ such that [\(5\)](#page-3-0) holds for κ being replaced by $\kappa_{\mathbb{I}}$. Then, one can simply set $\kappa =$ $\max_{\mathbb{I}\subseteq\mathbb{N}_{[1,n_c]}} \kappa_{\mathbb{I}}$, which is a uniform upper bound of Lipschitz constants over all subsets of $\mathbb{N}_{[1,n_c]}$. Thus, such a GLC always exists. In Section [IV-A,](#page-5-1) we shall provide formulas to compute this constant.

By [\(5\)](#page-3-0), it is trivial that $z^*(x, \mathbb{I}(x))$ lies in the ball with the center $z^*(\widehat{x}, \mathbb{I}(x))$ and a radius $\kappa ||x_1 - x_2||$, i.e.,

$$
z^*(x, \mathbb{I}(x)) \in \mathcal{B}(z^*(\widehat{x}, \mathbb{I}(x)), \kappa || \widehat{x} - x||). \tag{6}
$$

In comparison with [\(3a\)](#page-2-5), we only need to specify the unknown ball center $z^*(\hat{x}, \mathbb{I}(x))$ which in fact is exactly
the optimal solution of the solved mn $OP(\hat{x})$ i.e. $z^*(\hat{x})$ the optimal solution of the solved mp-QP(\hat{x}), i.e., $z^*(\hat{x}) = z^*(\hat{x} \mathbb{I}(x))$ if the index set $\mathbb{I}(x)$ is selected to satisfy $\mathbb{A}(\hat{x}) \subset$ $z^*(\hat{x}, \mathbb{I}(x))$, if the index set $\mathbb{I}(x)$ is selected to satisfy $\mathbb{A}(\hat{x}) \subseteq \mathbb{I}(x)$. Formally, we have the following result $\mathbb{I}(x)$. Formally, we have the following result.

Lemma 2: Given two parameter vectors $x, \hat{x} \in \mathbb{R}^{n_x}$, if $\mathbb{A}(\widehat{x}) \subseteq \mathbb{I}(x) \subseteq \mathbb{N}_{[1,n_c]},$ then $z^*(\widehat{x}, \mathbb{I}(x)) = z^*(\widehat{x}).$
Proof: Since $\mathbb{A}(\widehat{x}) \subseteq \mathbb{I}(x) \subseteq \mathbb{N}$, it holds *Proof:* Since $\mathbb{A}(\hat{x}) \subseteq \mathbb{I}(x) \subseteq \mathbb{N}_{[1,n_c]}$, it holds that

$$
V(z^*(\widehat{x}, \mathbb{A}(\widehat{x}))) \le V(z^*(\widehat{x}, \mathbb{I}(x))) \le V(z^*(\widehat{x})). \tag{7}
$$

By the definition of active set in [\(4\)](#page-3-1), it follows fro m [\[13\]](#page-13-10) that $V(z^*(\widehat{x}, \mathbb{A}(\widehat{x}))) = V(z^*(\widehat{x}))$. Jointly with [\(7\)](#page-3-2), it holds

$$
V(z^*(\hat{x}, \mathbb{A}(\hat{x}))) = V(z^*(\hat{x}, \mathbb{I}(x))) = V(z^*(\hat{x})).
$$
 (8)

Since both $z^*(\widehat{x}, \mathbb{I}(x))$ and $z^*(\widehat{x})$ belong to $\mathcal{Z}(\widehat{x}, \mathbb{A}(\widehat{x}))$,
by are two optimal solutions of the trimped mp OB of (2) they are two optimal solutions of the trimmed mp-QP of [\(2\)](#page-2-1) with $\mathbb{I}(x) = \mathbb{A}(\hat{x})$. By the uniqueness of its optimal solution, it follows that

$$
z^*(\widehat{x}, \mathbb{I}(x)) = z^*(\widehat{x})
$$
\n(9)

which completes the proof.

In view of [\(6\)](#page-3-3) and Lemma [2,](#page-3-4) let $\mathcal{M}(x) = \mathcal{B}(z^*(\widehat{x}), \kappa || x - \lambda)$. Then (3a) is insured as \widehat{x} ||). Then, [\(3a\)](#page-2-5) is insured as

$$
z^*(x, \mathbb{I}(x)) \in \mathcal{M}(x) \text{ if } \mathbb{A}(\widehat{x}) \subseteq \mathbb{I}(x). \tag{10}
$$

Note that it is easy to construct the pair of $\mathbb{I}(x)$ and $\mathcal{M}(x)$ as both $z^*(\hat{x})$ and $\mathbb{A}(\hat{x})$ are directly obtained from the solved mp-QP (\hat{x}) .

Next, we focus on the condition of [\(3b\)](#page-2-6) by further increasing the index set $\mathbb{I}(x)$. To elaborate it, we propose the following index set

$$
\mathbb{D}(x) = \{ j \in \mathbb{N}_{[1,n_c]} \mid \mathcal{M}(x) \subseteq \mathcal{Z}_j(x) \}. \tag{11}
$$

Since $\mathcal{M}(x)$ is a ball and $\mathcal{Z}_j(x)$ is a half-plane, then $\mathbb{D}(x)$ is also easy to obtain and will be detailed in Remark [3.](#page-4-0) Obviously, [\(11\)](#page-3-5) implies that $\mathcal{M}(x) \subseteq \mathcal{Z}(x,\mathbb{D}(x))$ and [\(3b\)](#page-2-6) is insured as

$$
\mathcal{M}(x) \subseteq \mathcal{Z}(x, \mathbb{C}(x)) \text{ if } \mathbb{C}(x) \subseteq \mathbb{D}(x). \tag{12}
$$

Jointly with $\mathbb{C}(x) = \mathbb{N}_{[1,n_c]} - \mathbb{I}(x)$, the condition [\(3\)](#page-2-4) holds for the pair of sets $\mathcal{M}(x) = \mathcal{B}(z^*(\widehat{x}), \kappa || x - \widehat{x} ||)$ and

$$
\mathbb{I}(x) = \mathbb{A}(\widehat{x}) \bigcup (\mathbb{N}_{[1,n_c]} - \mathbb{D}(x))
$$

= $\mathbb{A}(\widehat{x}) \bigcup (\mathbb{A}^c(\widehat{x}) - \mathbb{D}(x))$ (13)

where the so-called inactive set $\mathbb{A}^c(\hat{x})$ is the complement of $\mathbb{A}(\hat{x})$ and given as $A(\hat{x})$ and given as

$$
\mathbb{A}^{c}(\widehat{x}) := \{ j \in \mathbb{N}_{[1,n_c]} \mid G_j z^*(\widehat{x}) < w_j + S_j \widehat{x} \}.
$$

Remark 2: If the parameter vector x is close to \hat{x} , this implies that mp-QP(x) is also "close" to the solved mp-QP(\hat{x}) and it is expected that the results of mp-QP (\hat{x}) could provide useful information to trim mp-QP (x) . This can be justified from our design of $\mathbb{I}(x)$ and $\mathcal{M}(x)$. Specifically, if $||x - \hat{x}||$ is small, the set $\mathcal{M}(x)$ tends to be a small ball centered at $z^*(\hat{x})$. Jointly with that $z^*(\hat{x})$ is an interior of $\mathcal{Z}_j(x)$ for any $i \in \mathbb{A}^c(\hat{x})$ then $M(x) \subset \mathcal{Z}_j(x)$ could be notentially satisfied $j \in \mathbb{A}^c(\widehat{x})$, then $\mathcal{M}(x) \subseteq \mathcal{Z}_j(x)$ could be potentially satisfied.
This indicates that $\mathbb{D}(x) \sim \mathbb{A}^c(\widehat{x})$ and thus $\mathbb{I}(x) \sim \mathbb{A}(\widehat{x})$ (c f This indicates that $\mathbb{D}(x) \approx \mathbb{A}^c(\hat{x})$ and thus $\mathbb{I}(x) \approx \mathbb{A}(\hat{x})$ (c.f. Algorithm 1 Reliably learn to trim mp-QP of [\(1\)](#page-1-1) with a new parameter vector from a solved one

- **Input:** a GLC κ of [\(1\)](#page-1-1), and a pair $(z^*(\hat{x}), \mathbb{A}(\hat{x}))$ from the solved mp $OP(\hat{x})$ solved mp-OP (\hat{x})
- Output: a trimmed mp-QP in the form of [\(2\)](#page-2-1)
- 1: Compute [\(14\)](#page-4-1);
- 2: Set $\overline{\mathbb{I}}(x) = \mathbb{A}(\widehat{x}) \bigcup (\mathbb{A}^c(\widehat{x}) \mathbb{D}(x)).$

Fig. 2. A geometrical illustration of $\mathcal{B}(z^*(\widehat{x}), \kappa || x - \widehat{x} ||) \not\subseteq \mathcal{Z}_j(x)$.

[\(13\)](#page-3-6)). In this case, the feasible set in the trimmed mp- $QP(x)$ of [\(2\)](#page-2-1) tends to be $\mathcal{Z}(x, \mathbb{A}(\hat{x}))$, which is the minimum set of linear inequalities with zero optimality gap for $x = \hat{x}$.

Remark 3: We provide an explicit formula to compute $\mathbb{D}(x)$ in [\(11\)](#page-3-5). It is trivial that $\mathcal{B}(z^*(\hat{x}), \kappa || x - \hat{x} ||) \subseteq \mathcal{Z}_j(x)$ of (11) *if*
and only if (a) $z^*(\hat{x}) \in \mathcal{Z}_j(x)$ i.e. $C_z^*(\hat{x}) \leq x + S_x$ and *and only if* (a) $z^*(\hat{x}) \in \mathcal{Z}_j(x)$, i.e., $G_j z^*(\hat{x}) \leq w_j + S_j x$, and (b) the distance from the ball center $z^*(\hat{x})$ to the hyperplane (b) the distance from the ball center $z^*(\hat{x})$ to the hyperplane
of $\mathcal{Z}(x)$ should be greater than the ball radius $x||x - \hat{x}||$ of $\mathcal{Z}_i(x)$ should be greater than the ball radius $\kappa ||x - \hat{x}||$, i.e., $|w_j + S_j x - G_j z^*(\hat{x})|/||G_j|| \ge \kappa ||x - \hat{x}||$. See Fig. [2](#page-4-2) for an illustration of $\mathcal{B}(z^*(\hat{x}), \kappa || x - \hat{x}||) \nsubseteq \mathcal{Z}_j(x)$. Then, the set $A^{c}(\hat{x}) - D(x)$ of [\(13\)](#page-3-6) can be explicitly computed as

$$
\mathbb{A}^{c}(\widehat{x}) - \mathbb{D}(x)
$$
\n
$$
= \left\{ j \in \mathbb{A}^{c}(\widehat{x}) \, \left| \kappa \cdot \left\| x - \widehat{x} \right\| \right| > \frac{w_{j} + S_{j}x - G_{j}z^{*}(\widehat{x})}{\|G_{j}\|} \right\}.
$$
\n(14)

Remark 4: In light of [\(14\)](#page-4-1), the smaller the GLC κ , the smaller the number of elements of $\mathbb{A}^c(\hat{x}) - \mathbb{D}(x)$ tends to be
and thus the slimmar the trimmed mp OB of (2). In Section IV and thus the slimmer the trimmed mp-QP of [\(2\)](#page-2-1). In Section [IV](#page-5-0) of performance analysis, we shall provide an explicit formula to compute GLCs.

Before closing this subsection, we summarize our idea to trim mp-OP (x) in Algorithm [1.](#page-4-3) By Lemma [1,](#page-2-3) it is straightforward that the trimmed mp-QP of Algorithm [1](#page-4-3) does not change the optimal solution, which is formalized below.

Theorem 1: The trimmed mp-QP of Algorithm [1](#page-4-3) has the same optimal solution as that of the original mp-QP of [\(1\)](#page-1-1), i.e., $z^*(x, \mathbb{I}(x)) = z^*(x)$.

D. Learn to trim from multiple solved mp-QPs

In this subsection, we show how to efficiently use a sequence of pairs $\{(z^*(\hat{x}^k), A(\hat{x}^k))\}_{k \in \mathbb{N}_{[1,q]}}$ from multiple
solved mp OPs to refine $\mathbb{I}(x)$ and $M(x)$ of (3) Naively solved mp-QPs to refine $\mathbb{I}(x)$ and $\mathcal{M}(x)$ of [\(3\)](#page-2-4). Naively, one may consider to use the results of the mp-QP with the closest parameter vector. That is, we simply adopt Algorithm [1](#page-4-3) by selecting the solved mp-QP with the parameter vector as

 $\hat{x} \in \arg \min_{\hat{x}^k} {\|x - \hat{x}^k\|, k \in \mathbb{N}_{[1,q]}}$. Though simple, such an idea does not fully learn the results of these solved mn an idea does not fully learn the results of these solved mp-QPs and neglect most of their active sets which however are key information for trimming mp-QPs via removing redundant inequality constraints.

An ambitious goal is to simply apply Algorithm [1](#page-4-3) to each solved mp-QP(\hat{x}^k) in a parallel way and then take an intersection of their resultant index sets $\mathbb{I}^k(\infty)$? Unfortunately intersection of their resultant index sets $\mathbb{I}^k(x)$? Unfortunately, this idea may be problematic as illustrated below.

Example 1: Consider a one-dimensional mp-QP with $V(z) = z^2 + x \cdot z$, $\mathcal{Z}(x) = \{z \mid z \leq x, z \leq -x - 4\}$. Clearly, $\kappa = 1$ is a GLC of this problem. Suppose that we have solved mp-QP(-1) and mp-QP(-3), and obtain that

$$
z^*(-1) = -3, \mathbb{A}(-1) = \{2\} \text{ and}
$$

$$
z^*(-3) = -3, \mathbb{A}(-3) = \{1\}.
$$

 $G_j z = w_j + S_j x$ respectively, and obtain two trimmed mp-QPs with index sets of linear inequalities as $\mathbb{I}^1(-2) = \{2\}$ and $\mathbb{I}^2(-2) = \{1\}.$ One can easily verify that both trimmed mp-QPs have zero optimality gap, i.e., $z^*(-2, 1^1(-2)) = z^*(-2, 1^2(-2)) =$ $z^*(-2)$. If we simply take an intersection of the two index sets, the trimmed mp-QP with $\mathbb{I}(-2) = \mathbb{I}^1(-2) \cap \mathbb{I}^2(-2) = \emptyset$ cannot preserve the optimal solution of mp- $QP(-2)$, i.e., $z^*(-2,\bar{1}(-2)) \neq z^*(-2).$

> To remedy the issue in Example [1,](#page-4-4) we require the following linear independence constraint qualification (LICQ) condition.

> *Assumption 1:* (LICQ [\[14\]](#page-13-11)) For any parameter vector $x \in$ \mathcal{R}^{n_x} , the rows of $G_{\mathbb{A}(x)}$ are linearly independent.

> Under the LICQ condition of Assumption [1,](#page-4-5) the optimal solution can be specified by a unique minimum set of linear inequalities. That is, the trimmed mp-QP of [\(2\)](#page-2-1) with $\mathbb{I}(x) =$ $A(x)$ is the slimmest one that reserves the optimal solution of [\(1\)](#page-1-1). Such a minimum set of linear inequalities should be included in any trimmed mp-QP, and conversely, any trimmed mp-QP including this set does not change the optimal solution. See the proof of Lemma [2.](#page-3-4) Thus, the intersection of all index sets of $\overline{\mathbb{I}^k}(x)$, which is the resultant index set of Algorithm [1](#page-4-3) over the solved mp-QP(\hat{x}^k), will not incur any optimality
can It is worth mentioning that Assumption 1 ensures that gap. It is worth mentioning that Assumption [1](#page-4-5) ensures that the number of elements in the active set is less than n_z , i.e., $|A(x)| \leq n_z$. We summarize these results in Algorithm [2](#page-5-2) and show its optimality in the following proposition.

> *Theorem 2:* Under Assumption [1,](#page-4-5) the trimmed mp-QP of Algorithm [2](#page-5-2) has the same optimal solution as that of the original mp-QP of [\(1\)](#page-1-1), i.e., $z^*(x, \mathbb{I}(x)) = z^*(x)$.

Proof: See Appendix [B.](#page-10-0)

In fact, Algorithm [2](#page-5-2) can also be implemented in a parallel way where each processor k individually computes an index set $\mathbb{I}^k(x)$ as

$$
\mathbb{R}(x, \hat{x}^k) := \left\{ j \in \mathbb{A}^c(\hat{x}^k) \mid
$$

$$
\kappa \cdot ||x - \hat{x}^k|| > \frac{w_j + S_j x - G_j z^*(\hat{x}^k)}{||G_j||} \right\},\
$$

$$
\mathbb{I}^k(x) = \mathbb{A}(\hat{x}^k) \bigcup \mathbb{R}(x, \hat{x}^k)
$$

and then aggregates as $\mathbb{I}(x) = \bigcap_{k=1}^{q} \mathbb{I}^{k}(x)$.

Algorithm 2 Reliably learn from multiple solved mp-QPs to trim mp-QP with new parameter vectors

Input: a GLC κ of (1), and a sequence of pairs
$\left\{\left(z^*(\widehat{x}^k),\mathbb{A}(\widehat{x}^k)\right)\right\}_{k\in\mathbb{N}_{[1,q]}}$ from solved mp-QP(\widehat{x}^k)
Output: a trimmed mp-QP in the form of (2)
1: Set $k = 1$ and $\mathbb{I}(x) = \mathbb{N}_{[1,n_c]}$.
2: while $k \leq q$ do
3: Compute
$\mathbb{T}(x,\hat{x}^k) = \left\{ j \in \mathbb{A}^c(\hat{x}^k) \bigcap \mathbb{I}(x) \right\}$
$\kappa \cdot x - \widehat{x}^k > \frac{w_j + S_j x - G_j z^*(\widehat{x}^k)}{ G_i }$.
Set $\mathbb{I}(x) \leftarrow (\mathbb{A}(\hat{x}^k) \cap \mathbb{I}(x)) \cup \mathbb{T}(x, \hat{x}^k).$ 4:
$k \leftarrow k+1$. 5:
$6:$ end while

IV. PERFORMANCE ANALYSIS OF ALGORITHM [1](#page-4-3)

In this section, we first provide explicit formulas to compute the GLC. Then, we quantify the number of linear inequalities in the trimmed mp-QP of Algorithm [1.](#page-4-3)

A. Formulas to compute global Lipschitz constant

In Remark [4,](#page-4-6) we have briefly shown that the GLC is essential to the efficiency of our trimming algorithms in removing redundant inequalities. Here we develop explicit formulas to compute this constant.

Lemma 3: A global Lipschitz constant of [\(5\)](#page-3-0) is explicitly given as

$$
\kappa = \|H^{-1}F^T\| + \frac{1}{\min_{j \in \mathbb{N}_{[1,n_c]}} G_j H^{-1} G_j^T} \|H^{-1} G^T\|
$$

$$
\times \|S + GH^{-1} F^T\|.
$$
 (16)

Proof: See Appendix [A.](#page-9-1)

The GLC κ in [\(16\)](#page-5-3) is finite as H^{-1} is positive definite, and it is independent of the parameter vector x . Compared to the existing methods, e.g., the maximum norm of the explicit function [\[35\]](#page-13-27) and the mixed integer linear programming (MILP) [\[26\]](#page-13-23), [\[36\]](#page-13-28), our formula only involves computing some matrix inverse, matrix multiplication and matrix norm.

To further reduce the GLC, we can introduce a scaling matrix $\Phi \in \mathbb{R}^{n_c \times n_c}$ in [\(16\)](#page-5-3) where Φ should be a monotone matrix [\[37,](#page-13-29) Chapter 5], i.e., every element of Φ and Φ^{-1} are non-negative. Then, it holds that

$$
Gz \leq Sx + w \text{ if and only if } \Phi Gz \leq \Phi Sx + \Phi w. \tag{17}
$$

This implies that the mp-QP does not change at all after scaling the linear inequalities. However, one can obtain an improved GLC with the formula of Lemma [3.](#page-5-4)

Lemma 4: (Improved GLC) Given a monotone matrix $\Phi \in$ $R^{n_c \times n_c}$, a GLC of [\(5\)](#page-3-0) is explicitly given as

$$
\kappa_{\Phi} = \|H^{-1}F^T\| + \frac{1}{\min_{j \in \mathbb{N}_{[1,n_c]}} (\Phi G)_j H^{-1} (\Phi G)_j^T}
$$
 (18)

$$
\times \|H^{-1}G^T \Phi^T\| \|\Phi S + \Phi GH^{-1}F^T\|.
$$

If $\Phi = I$, then [\(18\)](#page-5-5) is clearly reduced to [\(16\)](#page-5-3). How to select a monotone matrix Φ to minimize κ_{Φ} is beyond the scope of this work. In Section [VI,](#page-8-0) we provide an empirical approach.

B. Performance evaluation of Algorithm [1](#page-4-3)

In this subsection, we evaluate the performance of Algorithm [1](#page-4-3) by quantifying the number of linear inequalities in the trimmed mp-QP of [\(2\)](#page-2-1). As noted in Remark [2,](#page-3-7) the closeness of \hat{x} to x is essential to the efficiency of removing redundant inequalities in mp- $QP(x)$. Thus, we adopt an increasing sequence of $\{\sigma_i\}$, which are specified as the infimum values of mixed integer linear programming (MILP) problems in the sequel, to classify the closeness between two parameter vectors, and use them to evaluate the quality of mp-QP (\hat{x}) in trimming mp- $QP(x)$. To this end, it follows from [\(13\)](#page-3-6) that the key is to quantify the cardinality of $D(x)$. Since it depends on both x and \hat{x} , i.e.,

$$
\mathbb{D}(x) = \left\{ j \in \mathbb{N}_{[1,n_c]} \left| \mathcal{B}(z^*(\widehat{x}), \kappa || x - \widehat{x} ||) \subseteq \mathcal{Z}_j(x) \right\}, \tag{19}
$$

we do not directly work on it, and instead lift both $\mathcal{Z}_i(x)$ and $\mathcal{B}(z^*(\hat{x}), \kappa || x - \hat{x} ||)$ to characterize their relation, based on which we provide a lower bound for the cardinality of $\mathbb{D}(x)$. which we provide a lower bound for the cardinality of $\mathbb{D}(x)$.

Consider a lifted version of the feasible set as

$$
\mathcal{V} = \{ v \mid Hv \le w \},\tag{20}
$$

where $v = [x', z']' \in \mathbb{R}^{n_v}$, $H = [-S, G] \in \mathbb{R}^{n_c \times n_v}$ and $n_v = n_x + n_z$. Accordingly, let $\mathcal{V}_j = \{v \mid H_j v \leq w_j\}$ for any $j \in \mathbb{N}_{[1,n_c]}$ and define

$$
v(\widehat{x}) = \left[\widehat{x}^T, z^*(\widehat{x})^T\right]^T \in \mathcal{R}^{n_v},\tag{21a}
$$

$$
\mathbb{E}(x) = \left\{ j \in \mathbb{N}_{[1,n_c]} \mid \mathcal{B}(v(\widehat{x}), \sqrt{1+\kappa^2} \|x - \widehat{x}\|) \subseteq \mathcal{V}_j \right\}.
$$
\n(21b)

Note that $V = \bigcap_{j \in \mathbb{N}_{[1,n_c]}} V_j$ is also a non-empty polyhedron, and we obtain following results.

Lemma 5: The sets in [\(21\)](#page-5-6) satisfy the following relation

(a)
$$
v(\widehat{x}) \in \mathcal{V}
$$
.
(b) $\mathbb{E}(x) \subseteq \mathbb{D}(x)$.

Proof: See Appendix [C.](#page-11-0)

By Lemma [5,](#page-5-7) it immediately implies that $v(\hat{x}) \in V_i$, i.e., the ball center $v(\hat{x})$ of [\(21b\)](#page-5-8) automatically lies in the lifted half-space V_j for any $j \in \mathbb{N}_{[1,n_c]}$, which is not the case for the set $\mathbb{D}(x)$ of [\(19\)](#page-5-9). From this view, it seems easier to numerate the element of $\mathbb{E}(x)$ than that of $\mathbb{D}(x)$. Since $v(\hat{x}) \in V$ holds automatically, we drop the dependence on the particular ball center in $E(x)$ by noting the following relation

$$
|\mathbb{E}(x)| \ge \inf_{v \in \mathcal{V}} \left| \left\{ j \in \mathbb{N}_{[1,n_c]} \mid \mathcal{B}(v, \sqrt{1+\kappa^2} \cdot ||x - \widehat{x}||) \subseteq \mathcal{V}_j \right\} \right|
$$

and then solely focus on the effect of ball radius via studying

$$
\inf_{v \in \mathcal{V}} \left| \left\{ j \in \mathbb{N}_{[1,n_c]} \mid \mathcal{B}(v,r) \subseteq \mathcal{V}_j \right\} \right| \in \mathbb{N}_{[0,n_c]}, \forall r \ge 0. \quad (22)
$$

Now, we are ready to specify the sequence of $\{\sigma_i\}$ to classify the distance between two parameter vectors, and then use them to find a lower bound on the cardinality of $E(x)$.

Lemma 6: For any $i \in \mathbb{N}_{[1,n_c]}$, let σ_i be the maximum value of the following optimization problem

$$
\sigma_i = \max_{r \ge 0} r,
$$
\n
$$
\text{s.t. } \min_{v \in \mathcal{V}} \left| \left\{ j \in \mathbb{N}_{[1, n_c]} \mid \mathcal{B}(v, r) \subseteq \mathcal{V}_j \right\} \right| \ge n_c - i. \tag{23b}
$$

Then, σ_i is finite and satisfies that

(a) $0 \leq \sigma_i \leq \sigma_{i+1}$. (b) If $v \in V$ and $0 \le r \le \sigma_i$, then

$$
\left| \left\{ j \in \mathbb{N}_{[1,n_c]} \mid \mathcal{B}(v,r) \subseteq \mathcal{V}_j \right\} \right| \ge n_c - i. \qquad (24)
$$

Proof: See Appendix [D.](#page-11-1)

Note that the attainability of maximization and minimization operators in [\(23\)](#page-6-1) are proved in Appendix [D.](#page-11-1) The problem of [\(23\)](#page-6-1) does not depend on parameter vectors, and can be computed in prior. Moreover, the optimal value of [\(23\)](#page-6-1) can be obtained via solving an MILP, which is formalized below.

Lemma 7: The optimal value of [\(23\)](#page-6-1) can be obtained via solving the following MILP.

$$
\sigma_i = \inf_{v \in \mathcal{V}, r \ge 0} r,
$$

s.t.
$$
\frac{w_j - H_j v}{\|H_j\|} - M\delta_j < r \le \frac{w_j - H_j v}{\|H_j\|} + M(1 - \delta_j),
$$

$$
\sum_{j=1}^{n_c} \delta_j < n_c - i, \delta_j \in \{0, 1\}, \ j \in \mathbb{N}_{[1, n_c]}.
$$
\n
$$
(25)
$$

where M is a big number [\[26\]](#page-13-23).

Proof: See Appendix [E.](#page-12-2)

Though the infimum in [\(25\)](#page-6-2) may not be attainable, it does not incur any trouble as [\(24\)](#page-6-3) only uses the value of σ_i .

Now, we use Lemma [6](#page-6-4) to quantify the number of linear inequalities in the trimmed mp-QP of [\(2\)](#page-2-1).

Theorem 3: Suppose that Assumption [1](#page-4-5) holds. If $||x - \hat{x}|| \leq$ $\sigma_i/\sqrt{1+\kappa^2}$ for some $i \in \mathbb{N}_{[1,n_c]}$, then $|\mathbb{I}(x)| \leq n_z + i$.

Proof: By Lemma [5](#page-5-7)[\(b\)](#page-5-10) and Lemma [6\(](#page-6-4)[b\)](#page-6-5), it holds that $|\mathbb{D}(x)| \geq |\mathbb{E}(x)| \geq n_c - i$. In addition, Assumption [1](#page-4-5) implies that $|A(\hat{x})| \leq n_z$. Then, it follows from [\(13\)](#page-3-6) that

$$
|\mathbb{I}(x)| \le n_z + n_c - |\mathbb{D}(x)| \le n_z + i
$$

which completes the proof.

Theorem [3](#page-6-6) shows that if the parameter vector \hat{x} of the solved
 $\Omega_{\mathbf{D}}(\hat{x})$ is close to $x \in \mathcal{X} \parallel x - \hat{x} \parallel \leq \pi/\sqrt{1 + x^2}$ then mp-QP(\hat{x}) is close to x, e.g., $||x - \hat{x}|| \le \sigma_i/\sqrt{1 + \kappa^2}$, then
the number of linear inequalities in the trimped mp OP of the number of linear inequalities in the trimmed mp-QP of Algorithm [1](#page-4-3) can be made less than $n_z + i$. Note that this number is generically very conservative, and the closer the distance between \hat{x} and x, the smaller this number in the trimmed mp-QP. If the number of linear inequalities n_c in mp- $QP(x)$ is significantly greater than the dimension of decision vector n_z , which is usually the case in many applications, the number of removed inequalities can be significant and thus trimming mp-QP is very rewarding in terms of removing redundant inequality constraints.

V. APPLICATION TO THE LINEAR QUADRATIC MPC

In this section, we shall learn to trim mp-QPs of the linear quadratic MPC whose parameter vector is the encountered state vector of a controlled system. Firstly, we introduce the linear MPC in the form of mp-QP. Then, we adaptively trim mp-QPs of MPC in the closed-loop system and show that the number of linear inequalities in the trimmed mp- $QP(x_k)$ decrease to zero after a finite timestep. Finally, we utilize offline solved mp-QPs to trim MPC.

A. The linear quadratic MPC

We consider the stabilization problem of a constrained linear time-invariant (LTI) system

$$
x_{k+1} = Ax_k + Bu_k \tag{26}
$$

with the state vector $x_k \in \mathcal{X} \subseteq \mathcal{R}^n$, the control input vector $u_k \in \mathcal{U} \subseteq \mathcal{R}^m$. The MPC is a well known methodology for synthesizing control laws of [\(26\)](#page-6-7) under the prescribed operating constraints, where the control action is obtained via solving a finite horizon open-loop optimal control problem [\[13,](#page-13-10) Chapter 2], *i.e.*,

$$
\min_{u_{\cdot|k}} J(x_{\cdot|k}, u_{\cdot|k})
$$
\n
$$
\text{s.t. } x_{t+1|k} = Ax_{t|k} + Bu_{t|k},
$$
\n
$$
x_{t|k} \in \mathcal{X}, u_{t|k} \in \mathcal{U}, t \in \mathbb{N}_{[0, N-1]},
$$
\n
$$
x_{N|k} \in \mathcal{X}_N,
$$
\n
$$
x_{0|k} = x_k.
$$
\n(27)

In this work, we assume that the above $\mathcal X$ and $\mathcal U$, and $\mathcal X_N$ are bounded polyhedral sets. Moreover, the objective function takes the following quadratic form

$$
J(x_{\cdot|k}, u_{\cdot|k}) = \sum_{t=0}^{N-1} (x_{t|k}^T Q x_{t|k} + u_{t|k}^T R u_{t|k}) + x_{N|k}^T P x_{N|k},
$$
\n(28)

with positive definite matrices Q, R, P . Since the predicted state vectors $x_{\cdot,k}$ can be linearly expressed by $u_{\cdot,k}$ and x_k , the linear quadratic MPC in [\(27\)](#page-6-8) can be reformulated as a mp-QP in the form of [\(1\)](#page-1-1) parameterized by x_k [\[1\]](#page-12-0).

Starting from an initial state $x_0 \in \mathcal{X}$, the MPC only applies the first input vector of the optimal sequence of [\(27\)](#page-6-8) to the system [\(26\)](#page-6-7), i.e.,

$$
u_{\rm MPC}(x_k) = u_{0|k}^*.
$$
\n⁽²⁹⁾

Under standard design choices, see e.g., [\[13,](#page-13-10) Chapter 2], the closed-loop system exponentially converges to the origin. In this work, we do not include the design details and simply make the following assumption.

Assumption 2: For the LTI system [\(26\)](#page-6-7) under the control law [\(29\)](#page-6-9), it holds that

- (a) The mp-QP in [\(27\)](#page-6-8) is recursively feasible starting from any $x_0 \in \mathcal{X}$.
- (b) The closed-loop system is exponentially stable, i.e., there exist positive constants $c > 0$ and $\beta \in (0, 1)$ such that $||x_k|| \leq c||x_0||\beta^k$.

For simplicity, we abuse notation in this section and simply assume that the mp-QP of MPC in [\(27\)](#page-6-8) is directly expressed

- • Input: a GLC κ of [\(1\)](#page-1-1).
- Repeat
- 1: Measure the system state vector x_k .
- 2: If $k = 0$, then let $\mathbb{I}(x_k) = \mathbb{N}_{[1, n_c]}$, **else** apply Algorithm [1](#page-4-3) with $(z^*(x_{k-1}), \mathbb{A}(x_{k-1}))$ to compute $\mathbb{I}(x_k)$.
- 3: Solve the trimmed mp-QP(x_k) with $\mathbb{I}(x_k)$ and record the results as $(z^*(x_k), \mathbb{A}(x_k)).$
- 4: Apply the first input vector of $z^*(x_k)$ to the LTI system as [\(29\)](#page-6-9).
- 5: $k \leftarrow k + 1$.

in the form of [\(1\)](#page-1-1) where $n_z = Nm$, $n_x = n$ and $n_c =$ $\#\mathcal{X}_N+N(\#\mathcal{X}+\#\mathcal{U})$ [\[26\]](#page-13-23) where $\#\mathcal{X}$ denotes the number of linear inequalities to specify the polyhedral set X . The goal of this section is to trim the mp- $QP(x_k)$ of [\(1\)](#page-1-1) where the parameter vector x_k is the state vector of the constrained LTI system [\(26\)](#page-6-7) under the control law [\(29\)](#page-6-9).

Different from the mp-QP of Section [III,](#page-2-0) we are interested in trimming mp-QPs in the closed-loop system whose state vector decreases to the origin (cf. Assumption [2\)](#page-6-10). This suggests that both the state difference $||x_k-x_{k-1}||$ and the number of linear inequalities in the trimmed mp- $QP(x_k)$ are expected to decrease to zero. This section rigorously provides an affirmative answer and shows that eventually we only need to solve a *constraint-free* mp-QP.

B. Adaptively trim mp-QPs of MPC in the closed-loop system

In this subsection, we use our trimming methods in Section [III](#page-2-0) to adaptively remove redundant inequality constraints in the mp-QP (x_k) of MPC, which is summarized in Algorithm [3.](#page-7-0) Then, we evaluate its performance by quantifying the number of linear inequalities in its trimmed version.

It should be noted that Algorithm [3](#page-7-0) requires to store the results of mp-QP at the last timestep. As the closed-loop system exponentially converges to the origin (cf. Assumption [2\)](#page-6-10), it is expected that the number of inequality constraints decreases and even to zero if $0 \in \text{int}(\mathcal{X}), 0 \in \text{int}(\mathcal{U})$ and $0 \in \text{int}(\mathcal{X}_N)$. Informally, if the origin lies in the boundary of a constraint set, there is at least one active linear inequality for the optimal solution of mp-QP(0) of MPC, and such an active inequality usually cannot be removed. See the discussion after Assumption [1.](#page-4-5)

Now we are ready to quantify the number of linear inequalities $|\mathbb{I}(x_k)|$ in the trimmed mp-QP(x_k) to evaluate the performance of Algorithm [3.](#page-7-0)

Theorem 4: Suppose that Assumptions [1](#page-4-5) and [2](#page-6-10) hold. Consider Algorithm [3,](#page-7-0) the following statements are in force

- (a) If $k \geq K_i$, then $|\mathbb{I}(x_k)| \leq n_z + i$.
- (b) If the origin is an interior of \mathcal{X}, \mathcal{U} and \mathcal{X}_N , then $|\mathbb{I}(x_k)| =$ 0 for all $k \geq \hat{K}$, where K_i and \hat{K} are given as

$$
K_{i} = \left\lceil \log_{\beta} \frac{\sigma_{i}}{c\|x_{0}\|(1+\beta^{-1})\sqrt{1+\kappa^{2}}} \right\rceil, \ i \in \mathbb{N}_{[1,n_{c}]}
$$

$$
\widehat{K} = \max\{\widehat{K}_{1}, \widehat{K}_{2}\}, \text{ and}
$$

$$
\widehat{K}_{1} = \max_{j \in \mathbb{N}_{[1,n_{c}]}} \left\lceil \log_{\beta} \frac{w_{j}}{c\|x_{0}\|\beta^{-1}(\kappa\|G_{j}\| + \|S_{j}\|)} \right\rceil,
$$

$$
\widehat{K}_{2} = \max_{j \in \mathbb{N}_{[1,n_{c}]}} \left\lceil \log_{\beta} \frac{w_{j}}{\rho_{j}} \right\rceil,
$$

$$
\rho_{j} = c\|x_{0}\| \left(\kappa \|G_{j}\|(1+\beta^{-1}) + \|S_{j}\| + \|G_{j}H^{-1}F^{T}\|\beta^{-1}\right).
$$

Proof: See Appendix F.

In view of Lemma [6,](#page-6-4) the sequence ${K_i}$ is decreasing and thus the upper bound of the number of inequality constraints in mp- $QP(x_k)$ decreases along with timestep.

For stabilization problem with MPC, it follows from [\(27\)](#page-6-8) that $z^*(0) = 0$. Jointly with [\(1b\)](#page-1-2), it implies that $w > 0$ and thus K is finite. Hence, the number of inequality constraints in the trimmed mp- $QP(x_k)$ decreases to zero after a finite timestep K .

C. Learn to trim MPC from offline solved mp-QPs

Of particular note is that our trimming algorithm cannot only reduce redundant inequalities from the previously solved mp-QPs in the online closed-loop system but also those in the offline design. To elaborate it, suppose that we have already solved q mp-QPs of MPC *offline* and obtained that

$$
\mathcal{D} = \{(\widehat{x}^i, z^*(\widehat{x}^i), \mathbb{A}(\widehat{x}^i))\}_{i \in \mathbb{N}_{[1,q]}}
$$
(30)

where \hat{x}^i corresponds to the parameter vector of an offline solved mn OP solved mp-QP.

In the online closed-loop system, we select a triple $(\hat{x}, z^*(\hat{x}), \mathbb{A}(\hat{x}))$ from [\(30\)](#page-7-1) with the parameter vector \hat{x} that is closest to x_i , i.e. is closest to x_k , i.e.,

$$
\widehat{x} = \operatorname{argmin}_{i \in \mathbb{N}_{[1,q]}} ||\widehat{x}^i - x_k|| \tag{31}
$$

instead of using all of them in Section [III-D,](#page-4-7) and then apply Algorithm [1](#page-4-3) to trim mp-QPs of MPC.

Remark 5 (Selection of parameter vectors of offline mp-QPs): By Theorem [3,](#page-6-6) the distance between parameter vectors of two mp-QPs is essential to reduce redundant inequalities. In this view, we should maximize the chance to find a nearby parameter vector of offline solved mp-QP, which motivates to adopt the Voronoi diagram [\[38\]](#page-13-30) to select parameter vectors. Specifically, they are chosen as the centroids of q -Voronoi cells $\{\mathcal{C}_i\}$ of the invariant set X, i.e.,

$$
\mathcal{C}_i = \{ x \in \mathcal{X} \mid ||x - \widehat{x}^i|| \le ||x - \widehat{x}^j||, \forall j \neq i \}, \ i \in \mathbb{N}_{[1,q]}.\tag{32}
$$

That is, Voronoi diagrams partition X into q-Voronoi cells, i.e., $\mathcal{X} = \bigcup_{i \in \mathbb{N}_{[1,q]}} \mathcal{C}_i$. In this case, the time complexity of [\(31\)](#page-7-2) is $\mathcal{O}(q)$.

An alternative is to use a grid partition of \mathcal{X} , and let \hat{x}^i be a grid points of the partition. Then, the time complexity in the grid points of the partition. Then, the time complexity in [\(31\)](#page-7-2) is $\mathcal{O}(\log(q))$.

By Theorem [3,](#page-6-6) we can easily show the performance of our trimming method using the data of offline solved mp-QPs in [\(30\)](#page-7-1). Particularly, we define the maximum distance of $\mathcal X$ as follows:

$$
d(\mathcal{X}, \mathcal{D}) = \max_{i \in \mathbb{N}_{[1,q]}} \max_{x \in \mathcal{C}_i} ||x - \widehat{x}^i||. \tag{33}
$$

Fig. 3. Voronoi diagrams. The rectangular region represents the feasible set \mathcal{X} , which is partitioned into five Voronoi cells using [\(32\)](#page-7-3).

 Corollary 1: Suppose that Assumption [1](#page-4-5) holds. If $d(\mathcal{X}, \mathcal{D}) \leq \sigma_i$ for some $i \in \mathbb{N}_{[1,n_c]}$, then $\overline{\mathbb{I}}(x_k)$ of the trimmed version of [\(27\)](#page-6-8) with offline solved mp-QPs in [\(30\)](#page-7-1) satisfies that

$$
\mathbb{I}(x_k) \le n_z + i \text{ for any } k \in \mathbb{N}.
$$

Clearly, the more offline solved mp-QPs used, the smaller the distance $d(\mathcal{X}, \mathcal{D})$, which potentially leads to a slimmer mp-QP for the trimmed version.

Remark 6 (Hybrid learning): Our trimming method can also easily take advantages of both offline and online solved mp-QPs, e.g., one can jointly use the previously solved mp-QP at one timestep lag of the closed-loop system and the closest mp-QP in D. See Section [III-D](#page-4-7) for details of learning from multiple solved mp-QPs.

Remark 7 (Comparison with the explicit MPC): The control law of the explicit MPC [\[15\]](#page-13-12) takes a piecewise affine structure in the parameter vector and can be obtained via solving mp-QP offline. To implement it online, one simply adopts the tablelookup method. However, the number of table cells grows exponentially with the dimension of mp-QP, and thus is only well suited for mp-QP with a moderate size. For example, we cannot implement the explicit MPC on our personal laptops for the second simulation in Section [VI.](#page-8-0) In comparison, our trimmed MPC is though not fully solved offline, it significantly takes benefits from offline solved mp-QPs to remove redundant constraints of mp-QP in the closed-loop system, based on which the trimmed mp-QPs can be much cheaper to solve online. Importantly, it is quite flexible and easy to take advantages of both offline and online solved mp-QPs.

VI. SIMULATION

In this section, we use our trimmed MPC to stabilize an oscillating mass system in [\[39,](#page-13-31) Section V-A]. It consists of six masses with unit value that are connected by springs (with the spring constants of 1). See Fig [4](#page-8-1) for an illustration. Let the state vector be the position and velocity of all masse, i.e., $x \in \mathcal{R}^{12}$. Three actuators exert tensions to masses under a maximum control force of ± 0.5 , and the displacements of masses cannot exceed ± 4 , i.e., $||x||_{\infty} \leq 4$ and $||u||_{\infty} \leq 0.5$. All the numerical experiments are implemented on a personal laptop with an Intel Core i5-11400F, 16 GB RAM.

Fig. 4. An oscillating mass system. The arrow denotes the direction of the force that is exerted to masses.

1 holds If algebraic Riccati equation, i.e., $P = A^T P A - A^T P B (R +$ $\|X \cdot \mathcal{L}_k\|_{\infty} \ge 0.0$. Specifically, we use $\|Y\|_{\infty}$ which results in 450 linear inequalities. One can easily verify $||K^*x_k||_{\infty} \leq 0.5$. Specifically, we use [\[40\]](#page-13-32) to compute \mathcal{X}_N , \mathcal{C}_2 \mathcal{C}_5 to discretize the continuous-time system at a sampling rate For the MPC design of [\(26\)](#page-6-7), we use the ZOH method $10Hz$, and adopt the procedures in [\[13,](#page-13-10) Chapter 2] to satisfy Assumption [2.](#page-6-10) In particular, let the weighing matrices Q, R be simply set as identity matrices, and P in the terminal cost is set as the positive definite solution to the discrete-time $B^T P B$)⁻¹ $B^T P A + Q$. Let the associated optimal gain be $K^* = -(R + B^T P B)^{-1} B^T P A$, based on which we set \mathcal{X}_N to be the maximal invariant set of the closed-loop system $x_{k+1} = (A + BK^*)x_k$ subject to $||x_k||_{\infty} \le 4$ and $||u_k||_{\infty} =$ that the mp-QP in [\(27\)](#page-6-8) is recursively feasible starting from any $x_0 \in \mathcal{X}_N$. Moreover, we randomly select 20 initial state vectors from X_N , each of which is run for 100 timesteps in the closed-loop systems under the control law in [\(29\)](#page-6-9), and report averaged results.

> Firstly, let the prediction horizon be $N = 30$, leading to that the dimensions of the resultant mp-QP are $n_x = 12$, $n_z =$ $30 \times 3 = 90$, $n_c = 30 \times (12 + 6) + 450 = 990$. In this horizon, we compare our trimmed MPC in Algorithm [3](#page-7-0) with the standard MPC, the MPC with warm-start, which initializes the iteration of the current mp-QP with the optimal solution of that at the previous step, and the ca-MPC in Nouwens et al. [\[22\]](#page-13-16). To implement Algorithm [3,](#page-7-0) the GLC $\kappa = 39.24$ is computed by [\(18\)](#page-5-5) where

$$
\Phi = \text{diag}\left(\left(G_1 H^{-1} G_1^T \right)^{-1/2}, \dots, \left(G_{n_c} H^{-1} G_{n_c}^T \right)^{-1/2} \right).
$$

Then, all the resultant mp-QPs are solved via *quadprog* in MATLAB 2023b with *active-set*. By setting the standard MPC as a baseline, we record the averaged percentages of computation time and constraints in Fig. [5,](#page-9-2) which indeed confirms superiorities of our trimming MPC. Eventually, we observe that both Algorithm [3](#page-7-0) and the ca-MPC in Nouwens et al. [\[22\]](#page-13-16) are constraint free. It should be noted that such an observation cannot be theoretically proved in [\[22\]](#page-13-16), which is not the case for Algorithm [3](#page-7-0) (cf. Theorem [4\)](#page-7-4).

Finally, we increase the prediction horizon to $N = 50$, leading to that the dimensions of the resultant mp-QP are n_x = 12, n_z = 150, n_c = 50 × 18 + 450 = 1350, and $\kappa = 57.11$. We use the MPT3 Toolbox [\[41\]](#page-13-33) to compute the explicit MPC. Unfortunately, the algorithm has run for more than 72 hours, finds more than 51954 regions and still does not terminate. To some extent, we are essentially unable to use the explicit MPC for this case in our laptop.

To illustrate our results in Section [V-C,](#page-7-5) we adopt the grid partition method in Remark [5](#page-7-6) over the invariant set \mathcal{X}_N and construct three data sets $\mathcal{D}_1, \mathcal{D}_2$ and \mathcal{D}_3 , whose details are

Fig. 5. The top subfigure shows the percentage of computation time with respect to the standard MPC and the bottom subfigure shows the percentage of inequality constraints remaining in the trimmed MPC.

TABLE I INFORMATION OF THE DATA SET

Data set	Coordinate distance	Number of data
		86
\mathcal{D}_2	0.25	312
		1105

reported in Table [I.](#page-9-3) Since the LICQ condition in Assumption [1](#page-4-5) holds, we jointly learn from both offline and online solved mp-QPs as stated in Remark [6.](#page-8-2) As shown in Fig. [6,](#page-9-4) the effect of offline solved mp-QPs decreases in timestep, and the online solved mp-QPs dominate the importance of removing constraints.

VII. CONCLUSION

In this work, we have presented novel methods to learn from the results of previously solved mp-QP(s) to accelerate the (unsolved) mp-QPs, which are reliably trimmed via constraint removal. Then, we extended to trim mp-QPs of MPC by utilizing both online and offline solved mp-QPs. Numerical results were included to support our theoretical findings. Overall, learning to remove redundant constraints appears to be a promising technique to solve a sequence of multiparametric programs, which will be further exploited in our future works.

APPENDIX

For writing brevity, we introduce some notations in this section. For any square matrix $A \in \mathbb{R}^{n \times n}$, let $\lambda_i(A)$ be the *i*-th largest eigenvalue of A and $\lambda_{\min}(A)$ is the smallest eigenvalue of A. For any matrix $A \in \mathbb{R}^{m \times n}$ and any set $\mathbb{I} \subseteq \mathbb{N}_{[1,m]}$, let $A_{\mathbb{I}}$ denote the submatrix that corresponds to the rows indexed by \mathbb{I} . For two vectors a and b of the same

Fig. 6. The percentage of the computation time and constraints with respect to the original MPC solution over time.

dimension, we denote their Hadamard product, i.e., pairwise product, by $a \circ b$.

A. Proof of Lemma [3](#page-5-4)

The KKT conditions of the trimmed mp-QP of [\(2\)](#page-2-1) with $\mathbb{I}(x) = \mathbb{I}$ [\[42,](#page-13-34) Section 3.4] are given as

$$
Hz + F^{T}x + G_{\mathbb{I}}^{T} \lambda = 0,
$$

\n
$$
\lambda \circ (G_{\mathbb{I}}z - w_{\mathbb{I}} - S_{\mathbb{I}}x) = 0,
$$

\n
$$
\lambda \ge 0,
$$

\n
$$
G_{\mathbb{I}}z \le w_{\mathbb{I}} + S_{\mathbb{I}}x.
$$
\n(34)

Then, consider the following equations

$$
Hz + F^T x + G^T \lambda = 0,\t(35a)
$$

$$
\lambda \circ (Gz - w - Sx) = 0,\tag{35b}
$$

$$
\lambda \geq 0. \tag{35c}
$$

First, we show that the set of primal solutions of [\(35\)](#page-9-5) can be given as

$$
\{z^*(x, \mathbb{I}) \mid \forall \mathbb{I} \subseteq \mathbb{N}_{[1, n_c]}\}\tag{36}
$$

where $z^*(x, \mathbb{I})$ is the primal solution of [\(34\)](#page-9-6). One one hand, for any $z^*(x, \mathbb{I})$ of [\(36\)](#page-9-7), there exists a dual vector $\lambda^*(x, \mathbb{I})$ such that the pair of primal-dual vectors $(z^*(x, \mathbb{I}), \lambda^*(x, \mathbb{I}))$ solves [\(34\)](#page-9-6). Then, we augment $\lambda^*(x, \mathbb{I})$ by padding zero elements to those positions in the complement of \mathbb{I} , and obtain a new vector $\lambda^* \in \mathcal{R}^{n_c}$, i.e., $\lambda^*_{\parallel} = \lambda^*(x, \mathbb{I})$ and $\lambda^*_{\parallel c} = 0$. One can validate that the pair of primal-dual vectors $(z^*(x, \mathbb{I}), \lambda^*)$ satisfies [\(35\)](#page-9-5). On the other hand, let (z^*, λ^*) be a pair of primal-dual vectors of [\(35\)](#page-9-5). Define the index set $\mathbb{I} = \{i \in \mathbb{R}_{[1,n_c]} \mid G_i z^* \leq \}$ $w_i + S_i x$. That is, $(z^*, \lambda_{\mathbb{I}}^*)$ satisfies [\(34\)](#page-9-6), and $z^* = z^*(x, \mathbb{I})$ is an element of [\(36\)](#page-9-7).

Then, we focus on the solution of [\(35\)](#page-9-5) which does not involve the index set \mathbb{I} . Clearly, solving [\(35a\)](#page-9-8) for z yields

$$
z = -H^{-1}(F^T x + G^T \lambda) \tag{37}
$$

and checking whether $G_i z - w_i - S_i x = 0$ obtains three submatrices $(\tilde{G}, \tilde{w}, \tilde{S})$, i.e.,

$$
\widetilde{G}z - \widetilde{w} - \widetilde{S}x = 0.
$$
 (38)

Without loss of generality, we assume that \tilde{G} has full row rank. Otherwise, we can follow the approach of [\[1\]](#page-12-0) to handle the degenerate issue. By [\(37\)](#page-9-9) and [\(38\)](#page-10-1), this implies that

$$
\widetilde{\lambda} = -(\widetilde{G}H^{-1}\widetilde{G}^T)^{-1}(\widetilde{w} + (\widetilde{S} + \widetilde{G}H^{-1}F^T)x)
$$

\n
$$
z = Lx + H^{-1}\widetilde{G}^T(\widetilde{G}H^{-1}\widetilde{G}^T)^{-1}\widetilde{w},
$$
\n(39)

where the gain $L = -H^{-1}F^{T} + H^{-1}\tilde{G}^{T}(\tilde{G}H^{-1}\tilde{G}^{T})^{-1}(\tilde{S} + \tilde{G}^{T}T)$ $\widetilde{G}H^{-1}F^T$).

Thus, the GLC can be given by finding an upper bound of the spectral norm of L for every tuple (G, \tilde{w}, S) . It follows from the definition of L that

$$
||L|| \le ||H^{-1}F^T|| + ||H^{-1}\widetilde{G}^T(\widetilde{G}H^{-1}\widetilde{G}^T)^{-1}(\widetilde{S} + \widetilde{G}H^{-1}F^T)||
$$
(40)

In fact, the matrices \tilde{G} and \tilde{S} can be represented as follows:

$$
\tilde{G} = JG, \ \tilde{S} = JS.
$$

where J has at most one entry of 1 in each row and each column with all other entries 0. Substituting this into the second term of [\(40\)](#page-10-2) yields

$$
||H^{-1}\tilde{G}^T(\tilde{G}H^{-1}\tilde{G}^T)^{-1}(\tilde{S} + \tilde{G}H^{-1}F^T)||
$$

=
$$
||H^{-1}G^T J^T (JGH^{-1}G^T J^T)^{-1} (JS + JGH^{-1}F^T)||
$$

$$
\leq ||H^{-1}G^T|| ||J^T|| || (JGH^{-1}G^T J^T)^{-1}|| ||J|| ||S + GH^{-1}F^T||,
$$

where the last inequality follows from the submultiplicative property of the spectral norm. Since $(JGH^{-1}G^TJ^T)^{-1}$ is positive definite matrix, it follows that

$$
||(JGH^{-1}G^{T}J^{T})^{-1}|| = \lambda_{1}((JGH^{-1}G^{T}J^{T})^{-1})
$$

= 1/ $\lambda_{\min}(JGH^{-1}G^{T}J^{T})$.

In addition, $||J^T|| = ||J|| = 1$. Together with [\(40\)](#page-10-2), it can be concluded that

$$
||L|| \le ||H^{-1}F^T|| + ||H^{-1}G^T||
$$

$$
\times ||S + GH^{-1}F^T|| / \lambda_{\min}(JGH^{-1}G^TJ^T).
$$
 (41)

Let $H^{-1} = LL^T$ (i.e. Cholesky decomposition) where L has full rank, and $Y = GL$. Since the matrices $JYY^T J^T$ and $Y^T J^T J Y$ have the same non-zero eigenvalues of which the number is $|A(x)|$, it follows that

$$
\lambda_{\min}(JGH^{-1}G^TJ^T) = \lambda_{\min}(JYY^TJ^T)
$$

= $\lambda_{|\mathbb{A}(x)|}(Y^TJ^TJY) = \lambda_{|\mathbb{A}(x)|}(\sum_{j \in \mathbb{A}(x)} Y_j^T Y_j).$ (42)

In view of [\[43,](#page-13-35) Corollary 4.3.15.], for any $j_0 \in A(x)$, it holds that

$$
\lambda_{|\mathbb{A}(x)|}(\sum_{j\in\mathbb{A}(x)} Y_j^T Y_j) \geq \lambda_{|\mathbb{A}(x)|}(\sum_{j\in\mathbb{A}(x),j\neq j_0} Y_j^T Y_j) + \lambda_1(Y_{j_0}^T Y_{j_0}),
$$

Since the rank of $\sum_{j \in \mathbb{A}(x), j \neq j_0} Y_j^T Y_j$ is less than $|\mathbb{A}(x)|$, its $|\mathbb{A}(x)|$ -th largest eigenvalue is zero. Moreover, $\lambda_1(Y_{j_0}^T Y_{j_0}) =$ $Y_{j_0} Y_{j_0}^T$. It follows that

$$
\lambda_{|\mathbb{A}(x)|} (\sum_{j \in \mathbb{A}(x)} Y_j^T Y_j) \ge Y_{j_0} Y_{j_0}^T
$$
\n
$$
\ge \min_{j \in \mathbb{N}_{[1,n_c]}} Y_j Y_j^T = \min_{j \in \mathbb{N}_{[1,n_c]}} G_j H^{-1} G_j^T. \tag{43}
$$

where the last inequality follows from $H^{-1} = LL^T$ and $Y =$ GL. Combing [\(41\)](#page-10-3)-[\(43\)](#page-10-4) leads to

$$
||L|| \le ||H^{-1}F^T||
$$

+
$$
\frac{1}{\min_{j \in \mathbb{N}_{[1,n_c]}} G_j H^{-1} G_j^T} ||H^{-1} G^T|| ||S + GH^{-1} F^T||,
$$

which completes the proof.

B. Proof of Theorem [2](#page-4-8)

Recall that Algorithm [2](#page-5-2) trims the mp-QPs by the intersection of all index sets of $\mathbb{I}^k(x)$, which is the resultant index set of Algorithm [1](#page-4-3) over the solved mp-QP(\hat{x}^k). That is,

$$
\mathbb{I}(x) = \bigcap_{k=1}^{q} \mathbb{I}^{k}(x),\tag{44}
$$

where $\mathbb{I}^k(x) = \mathbb{A}(\hat{x}^k) \cup \mathbb{R}(x, \hat{x}^k)$.

It follows from *KKT* conditions

It follows from KKT conditions of [\(1\)](#page-1-1) and [\(2\)](#page-2-1) with $\mathbb{I}(x) =$ $\mathbb{I}^k(x)$ that

$$
Hz^*(x) + F^T x + G^T \lambda^*(x) = 0,
$$

\n
$$
Hz^*(x, \mathbb{I}^k(x)) + F^T x + G^T_{\mathbb{I}^k(x)} \lambda^*(x, \mathbb{I}^k(x)) = 0,
$$

where $\lambda^*(x)$, $\lambda^*(x, \mathbb{I}^k(x))$ are the Lagrange multipliers of the mp-QP (1) and the trimmed mp-QP (2) with the index set $\mathbb{I}^k(x)$, respectively. Since Theorem [1](#page-4-9) ensures that $z^*(x, \mathbb{I}^k(x)) = z^*(x)$, it follows that

$$
G^T \lambda^*(x) = G_{\mathbb{I}^k(x)}^T \lambda^*(x, \mathbb{I}^k(x)).
$$
 (46)

Clearly, $\lambda^*(x)$ is non-negative, and we denote the strict positive elements by $\underline{\mathbb{A}}(x) = \{j \in \mathbb{N}_{[1,n_c]} \mid \lambda_j^*(x) > 0\}$. Let $A(x, \mathbb{I}^k(x))$ denote the set of indices of active constraints in the trimmed mp-QP [\(2\)](#page-2-1) with the index set $\mathbb{I}^k(x)$. Moreover, in view of the complementarity slackness [\[42\]](#page-13-34), $\lambda_j^*(x, \mathbb{I}^k(x)) = 0$ for any $j \notin A(x, \mathbb{I}^k(x))$. It follows from [\(46\)](#page-10-5) that

$$
\sum_{j \in \underline{\mathbb{A}}(x)} G_j^T \lambda_j^*(x) = \sum_{j \in \mathbb{A}(x, \mathbb{I}^k(x))} G_j^T \lambda_j^*(x, \mathbb{I}^k(x)). \tag{47}
$$

Note that both $\underline{\mathbb{A}}(x)$ and $\mathbb{A}(x,\mathbb{I}^k(x))$ are subsets of $\mathbb{A}(x)$. Under Assumption [1,](#page-4-5) [\(47\)](#page-10-6) implies that $\underline{\mathbb{A}}(x) \subseteq \mathbb{A}(x,\mathbb{I}^k(x)).$ Then, $\underline{\mathbb{A}}(x) \subseteq \mathbb{I}^k(x)$. It follows from [\(44\)](#page-10-7) that $\underline{\mathbb{A}}(x) \subseteq \mathbb{I}(x)$.

Since $\mathbb{A}(x) \subseteq \mathbb{I}(x)$, $z^*(x)$ and $\lambda^*_{\mathbb{I}(x)}(x)$ satisfy the KKT conditions of the mp-QP [\(2\)](#page-2-1). Thus, $z^*(x)$ is also the optimal solution of the mp-QP [\(2\)](#page-2-1). By the uniqueness of its optimal solution, it follows that

$$
z^*(\widehat{x}, \mathbb{I}(x)) = z^*(\widehat{x})
$$

which completes the proof.

C. Proof of Lemma [5](#page-5-7)

[\(a\)](#page-5-11) Since $z^*(\hat{x})$ is the optimal solution of mp-QP in [\(1\)](#page-1-1),
 $(z^*) \in \mathcal{Z}(\hat{x})$ i.e. $Cz^*(\hat{x}) \leq W + S\hat{x}$. This vial $ds_0(\hat{x}) \in \mathcal{Y}$, $z^*(\hat{x}) \in \mathcal{Z}(\hat{x})$, i.e., $Gz^*(\hat{x}) \leq W + S\hat{x}$. This yields $v(\hat{x}) \in V$.
(b) Consider any $i \in \mathbb{F}(x)$. For any $g \in \mathcal{B}(z^*(\hat{x}) \cup |x-\hat{x}|)$.

[\(b\)](#page-5-10) Consider any $j \in \mathbb{E}(x)$. For any $q \in \mathcal{B}(z^*(\hat{x}), \kappa || x - \hat{x} ||)$, $w = [x', a']'$, it holds that $||w - \hat{w}(\hat{x})|| \leq \sqrt{1 + x^2} ||x - \hat{x}||$. (b) Consider any $j \in \mathbb{E}(x)$. For any $q \in \mathcal{B}(z^-(x), \kappa ||x-x||)$,

let $v_1 = [x', q']'$. It holds that $||v_1 - v(\hat{x})|| \le \sqrt{1 + \kappa^2} ||x - \hat{x}||$.

It follows from (21b) that $H, v_1 \le w$. Beautifing it viables It follows from [\(21b\)](#page-5-8) that $H_i v_1 \leq w_i$. Rewriting it yields that $Gq \leq W + Sx$, i.e., $q \in \mathcal{Z}_i(x)$. This implies that $\mathcal{B}(z^*(\hat{x}), \kappa || x - \hat{x} ||) \subseteq \mathcal{Z}_j(x)$. It follows from [\(11\)](#page-3-5) that $i \in \mathbb{D}(\alpha)$. Thus $\mathbb{F}(\alpha) \subseteq \mathbb{D}(\alpha)$. $j \in \mathbb{D}(x)$. Thus, $\mathbb{E}(x) \subseteq \mathbb{D}(x)$.

D. Proof of Lemma [6](#page-6-4)

This proof starts with the following lemma.

Lemma 8: The supremum and infimum of a finite integer set can be attained and are integers in the set, i.e.,

If
$$
S \subseteq \mathbb{N}_{[a,b]}
$$
, then sup S , inf $S \in S$.

Proof: Suppose that s is the infimum of S. Then, for every $n \in \mathbb{N}$, there exists $s_n \in S$ such that

$$
s \le s_n < s + \frac{1}{n+2}.
$$

Note that for all $n, m \in \mathbb{N}$, it follows that

$$
|s_n - s_m| \le |s_n - s| + |s_m - s| < \frac{1}{n+2} + \frac{1}{m+2} \le 1.
$$

Since $s_n, s_m \in \mathbb{N}_{[a,b]}$, we obtain that $s_n = s_m$. That is, there exists $\widetilde{s} \in S$ such that $s \leq \widetilde{s} < s + 1/(n + 2)$ for any $n \in \mathbb{N}$. Thus, $s = \tilde{s} \in S$. The same goes for its supremum.

The remaining proof is organized as four following parts.

1) Existence of minimum in [\(23b\)](#page-6-11). Define the function

$$
S(v,r) = |\{j \in \mathbb{N}_{[1,n_c]} \mid \mathcal{B}(v,r) \subseteq \mathcal{V}_j\}| \tag{48}
$$

Clearly, for any $r \geq 0$, $\{S(v,r) \mid v \in V\} \subseteq \mathbb{N}_{[0,n_c]}$. In view of Lemma [8,](#page-11-2) the minimum in [\(23b\)](#page-6-11) exists.

2) Existence of maximum in [\(23\)](#page-6-1). Define the functions

$$
\epsilon(x) := \begin{cases} 1, & x \ge 0 \\ 0, & x < 0 \end{cases}, \quad \delta(x) := \begin{cases} 1, & x > 0 \\ 0, & x \le 0 \end{cases}.
$$

Clearly, $\epsilon(x) + \delta(-x) = 1$ for any $x \in \mathcal{R}$. Indeed, $\mathcal{B}(v, r) \subseteq$ \mathcal{V}_i if and only if (a) $H_i v \leq w_i$ and (b) $r \leq |w_i - H_i v| / ||H_i||$ (c.f. Remark [3\)](#page-4-0). Thus, for any $v \in V$, the function $S(v, r)$ can be expressed as follows:

$$
S(v,r) = \sum_{j=1}^{n_c} \epsilon \left(\frac{w_j - H_j v}{\|H_j\|} - r \right)
$$

$$
= n_c - \sum_{j=1}^{n_c} \delta \left(r - \frac{w_j - H_j v}{\|H_j\|} \right)
$$

Then, the inequality [\(23b\)](#page-6-11) can be rewritten as follows:

$$
\max_{v \in \mathcal{V}} \sum_{j=1}^{n_c} \delta\left(r - \frac{w_j - H_j v}{\|H_j\|}\right) \leq i.
$$

and [\(23\)](#page-6-1) can be rewritten as follows:

$$
\max_{r\geq 0} r,
$$
\n
$$
\text{s.t. } \max_{v\in V} \sum_{j=1}^{n_c} \delta\left(r - \frac{w_j - H_j v}{\|H_j\|}\right) \leq i. \tag{49}
$$

The following lemma shows that the maximum of [\(49\)](#page-11-3) can be attained, which implies that σ_i exists and is finite.

Lemma 9: The maximum of the optimization problem [\(49\)](#page-11-3) can be attained.

Proof: We denote the feasible region of variable r in [\(49\)](#page-11-3) as Γ_i . Consider any closure point \tilde{r} of Γ_i . It follows from the definition of closure point that there exists a sequence the definition of closure point that there exists a sequence $\Delta r_k \to 0$ such that $\widetilde{r} + \Delta r_k \in \Gamma_i$. That is, for any $k \in \mathbb{N}$,

$$
\max_{v \in \mathcal{V}} \sum_{j=1}^{n_c} \delta\left(\widetilde{r} - \frac{w_j - H_j v}{\|H_j\|} + \Delta r_k\right) \le i,
$$
 (50)

and $\widetilde{r} + \Delta r_k \geq 0$.

Here, we consider two cases.

(i) If there exists $k_0 \in \mathbb{N}$ such that $\Delta r_{k_0} \geq 0$, then

$$
\max_{v \in \mathcal{V}} \sum_{j=1}^{n_c} \delta\left(\widetilde{r} - \frac{w_j - H_j v}{\|H_j\|}\right)
$$

$$
\leq \max_{v \in \mathcal{V}} \sum_{j=1}^{n_c} \delta\left(\widetilde{r} - \frac{w_j - H_j v}{\|H_j\|} + \Delta r_{k_0}\right) \leq i.
$$

where the first inequality holds because the function $\delta(\cdot)$ is nondecreasing and the second inequality follows from [\(50\)](#page-11-4).

(ii) Otherwise, $\Delta r_k \leq 0$ for any $k \in \mathbb{N}$. Define the functions

$$
f(v) = \sum_{j=1}^{n_c} \delta\left(\widetilde{r} - \frac{w_j - H_j v}{\|H_j\|}\right),
$$

$$
f_k(v) = \sum_{j=1}^{n_c} \delta\left(\widetilde{r} - \frac{w_j - H_j v}{\|H_j\|} + \Delta r_k\right).
$$

Since dom $f(v)$ and dom $f_k(v) \subseteq \mathbb{N}_{[0,n_c]}$, the supremum of $f(v)$, $f_k(v)$ can be attained in view of Lemma [8.](#page-11-2) Let v^* , v_k^* be the maximizers of $f(v)$, $f_k(v)$ respectively. It follows that

$$
\lim_{k \to \infty} f_k(v_k^*) \ge \lim_{k \to \infty} f_k(v^*) = f(v^*). \tag{51}
$$

where the equality holds because the function $\delta(\cdot)$ is leftcontinuous. Since $f(v^*) \ge f(v_k^*)$, we have that

$$
f(v^*) \ge \lim_{k \to \infty} f(v_k^*) \ge \lim_{k \to \infty} f_k(v_k^*)
$$
 (52)

Combing [\(51\)](#page-11-5) and [\(52\)](#page-11-6) yields that $f(v^*) = \lim_{k \to \infty} f_k(v_k^*)$. That is,

$$
\max_{v \in \mathcal{V}} \sum_{j=1}^{n_c} \delta\left(\widetilde{r} - \frac{w_j - H_j v}{\|H_j\|}\right)
$$

=
$$
\lim_{k \to \infty} \max_{v \in \mathcal{V}} \sum_{j=1}^{n_c} \delta\left(\widetilde{r} - \frac{w_j - H_j v}{\|H_j\|} + \Delta r_k\right) \leq i.
$$

where the inequality follows from (50) . Finally, it can be concluded that:

$$
\max_{v\in\mathcal{V}}\sum_{j=1}^{n_c}\delta\left(\widetilde{r}-\frac{w_j-H_jv}{\|H_j\|}\right)\leq i.
$$

In addition, since $\tilde{r} + \Delta r_k \ge 0$ and $\Delta r_k \to 0$, $\tilde{r} \ge 0$. Thus, $\widetilde{r} \in \Gamma_i$ and Γ_i is closed. Moreover, Γ_i is nonempty because $0 \in \Gamma_i$. The optimization function $f(r) = r$ is continuous $0 \in \Gamma_i$. The optimization function $f(r) = r$ is continuous and coercive. It follows from [\[42,](#page-13-34) Proposition A.8] that the maximum of [\(49\)](#page-11-3) can be attained.

3) Proof of [\(a\)](#page-6-12). The inequality in [\(23a\)](#page-6-13) yields $\sigma_i \geq 0$. Clearly, $\Gamma_i \subseteq \Gamma_{i+1}$ which is the notation in Lemma [9.](#page-11-7) Thus, $\sigma_i \leq \sigma_{i+1}.$

4) Proof of [\(b\)](#page-6-5). It follows that

$$
S(v,r) \geq S(v,\sigma_i)
$$

\n
$$
\geq \min_{v \in \mathbb{V}} |\{j \in \mathbb{N}_{[1,n_c]} \mid \mathcal{B}(v,\sigma_i) \subseteq \mathcal{V}_j\}| \geq n_c - i.
$$

where the first inequality follows from $\mathcal{B}(v,r) \subseteq \mathcal{B}(v,\sigma_i)$.

E. Proof of Lemma [7](#page-6-14)

First, we give an alternative computation method of σ_i as follows:

Lemma 10: For any $i \in \mathbb{N}_{[1,n_c]}$, $\sigma_i = \overline{\sigma}_i$ where

$$
\overline{\sigma}_{i} = \inf_{v \in \mathcal{V}, r \ge 0} r,
$$
\n
$$
\text{s.t. } \left| \left\{ j \in \mathbb{N}_{[1, n_c]} \mid \mathcal{B}(v, r) \subseteq \mathcal{V}_j \right\} \right| < n_c - i. \tag{53b}
$$

Proof: One the one hand, since
$$
\overline{\sigma}_i
$$
 is the infimum of (53),

for any $\epsilon_1 > 0$, there exist $v_1 \in V$, $r_1 \geq 0$ such that

$$
\left| \left\{ j \in \mathbb{N}_{[1,n_c]} \mid \mathcal{B}(v_1, r_1) \subseteq \mathcal{V}_j \right\} \right| < n_c - i \tag{54}
$$

and $r_1 \leq \overline{\sigma}_i + \epsilon_1$. Note that $r_1 > \sigma_i$, otherwise

$$
\min_{v \in \mathcal{V}} \left| \left\{ j \in \mathbb{N}_{[1,n_c]} \mid \mathcal{B}(v, r_1) \subseteq \mathcal{V}_j \right\} \right|
$$
\n
$$
\geq \min_{v \in \mathcal{V}} \left| \left\{ j \in \mathbb{N}_{[1,n_c]} \mid \mathcal{B}(v, \sigma_i) \subseteq \mathcal{V}_j \right\} \right| \geq n_c - i
$$

which leads to a contradiction with [\(54\)](#page-12-4). Thus, $\sigma_i \leq \overline{\sigma}_i + \epsilon_1$ for any $\epsilon_1 > 0$, i.e., $\sigma_i \leq \overline{\sigma}_i$.

On the other hand, since σ_i is the maximum of [\(23\)](#page-6-1), then for any $\epsilon_2 > 0$, there exists $v_2 \in V$ such that

$$
\left| \left\{ j \in \mathbb{N}_{\left[1, n_c \right]} \mid \mathcal{B}(v_2, \sigma_i + \epsilon_2) \subseteq \mathcal{V}_j \right\} \right| < n_c - i
$$

which implies that $\overline{\sigma}_i \leq \sigma_i + \epsilon_2$. Thus, $\overline{\sigma}_i \leq \sigma_i$.

To conclude, $\sigma_i = \overline{\sigma}_i$.

We next show how to reformulate the optimization problem [\(53\)](#page-11-8) into an MILP. We introduce binary variables $\delta_j \in$ $\{0,1\}, \ j \in \mathbb{N}_{[1,n_c]}$ to represent that $\mathcal{B}(v,r) \subseteq \mathcal{V}_j$, i.e., $\delta_j = 1$ if $\mathcal{B}(v,r) \subseteq V_j$ and $\delta_j = 0$, otherwise. Since $\mathcal{B}(v,r) \subseteq V_j$ if and only if (a) $H_i v \leq w_i$ and (b) $r \leq |w_i - H_i v|/||H_i||$ (c.f. Remark [3\)](#page-4-0), the logical implication of δ_j can translate into the mixed integer inequality

$$
\frac{w_j - H_j v}{\|H_j\|} - M\delta_j < r \le \frac{w_j - H_j v}{\|H_j\|} + M(1 - \delta_j),
$$

where M is a large number [\[26\]](#page-13-23). To sum up, the optimization problem in [\(53\)](#page-11-8) is reformulated as the following MILP problem:

$$
\overline{\sigma}_{i} = \inf_{v \in \mathcal{V}, r \ge 0} r,
$$

s.t.
$$
\frac{w_{j} - H_{j}v}{\|H_{j}\|} - M\delta_{j} < r \le \frac{w_{j} - H_{j}v}{\|H_{j}\|} + M(1 - \delta_{j}),
$$

$$
\sum_{j=1}^{n_{c}} \delta_{j} < n_{c} - i, \ \delta_{j} \in \{0, 1\}, \ j \in \mathbb{N}_{[1, n_{c}]}.
$$
\n(55)

By Lemma [10,](#page-12-5) computing σ_i amounts to an MILP [\(55\)](#page-12-6).

F. Proof of Theorem [4](#page-7-4)

[\(a\)](#page-7-7): Assumption [2](#page-6-10) implies $||x_k|| \le c||x_0||\beta^k$. Thus, $||x_k$ x_{k-1} || ≤ || x_k || + || x_{k-1} || ≤ c || x_0 || $\beta^k(1+\beta^{-1})$. If $k \geq K_i$, then

$$
||x_k - x_{k-1}|| \le c ||x_0|| \beta^{K_i} (1 + \beta^{-1}) = \frac{\sigma_i}{\sqrt{1 + \kappa^2}}.
$$

It follows from Theorem [3](#page-6-6) that $|\mathbb{I}(x_k)| \leq n_z + i$.

[\(b\)](#page-7-8): It follows from [\(13\)](#page-3-6) that

$$
\mathbb{I}(x_k) = \mathbb{A}(x_{k-1}) \bigcup (\mathbb{A}^c(x_{k-1}) - \mathbb{D}(x_k)).
$$

Thus, $|\mathbb{I}(x_k)| = 0$ if and only if (i) $\mathbb{A}(x_{k-1}) = \emptyset$ and (ii) $\mathbb{D}(x_k) = \mathbb{N}_{[1,n_c]}$ where $\mathbb{D}(x_k)$ has the form as

$$
\{j \in \mathbb{N}_{[1,n_c]} \mid \mathcal{B}(z^*(x_{k-1}), \kappa \|x_k - x_{k-1}\|) \subseteq \mathcal{Z}_j(x_k)\} \tag{56}
$$

We first show that $\mathbb{A}(x_{k-1}) = \emptyset$. Note that the mp-QP(0) of MPC can be trivially solved as $z^*(0) = 0$ with $\mathbb{A}^*(0) = \emptyset$. Since the origin is an interior of X, U and X_N , all constraints in the mp-QP(0) are active, i.e., $G0 < w + Sz^*(0)$. Thus, $w > 0$. Let $\hat{x} = 0$ and $\mathbb{I}(x) = \mathbb{A}(x_{k-1})$ in [\(6\)](#page-3-3). It follows that $z^*(x_{k-1}) \in \mathcal{B}(\mathbf{0}, \kappa || x_{k-1} ||)$. Then,

$$
G_j z^* (x_{k-1}) - S_j x_{k-1} - w_j
$$

\n
$$
\leq \kappa ||G_j|| ||x_{k-1}|| + ||S_j|| ||x_{k-1}|| - w_j
$$

\n
$$
\leq c ||x_0||(\kappa ||G_j|| + ||S_j||)\beta^{k-1} - w_j
$$

\n
$$
\leq c ||x_0||(\kappa ||G_j|| + ||S_j||)\beta^{\widehat{K}_1 - 1} - w_j.
$$

where the second inequality follows from Assumption [2](#page-6-10) and the third from $k \geq \hat{K} \geq \hat{K}_1$. Substituting the definition of $\widehat{K}_1, G_j z^*(x_{k-1}) - S_j x_{k-1} - w_j < 0$ for any $j \in \mathbb{N}_{[1,n_c]}$, i.e., $\mathbb{A}(x_{k-1}) = \emptyset.$

We next show that $\mathbb{D}(x_k) = \mathbb{N}_{[1,n_c]}$. According to [\(56\)](#page-12-7), $j \in \mathbb{D}(x_k)$ if and only if (i) $G_j z^*(x_{k-1}^{(i)}) \leq S_j x_k + w_k$ and (ii) $|w_j + S_j x_k - G_j z^*(x_{k-1})| / ||G_j|| \geq \kappa ||x_k - x_{k-1}||$ (c.f. Remark [3\)](#page-4-0). The necessary and sufficient condition can be merged as

$$
\kappa ||G_j|| ||x_k - x_{k-1}|| \le w_j + S_j x_k - G_j z^*(x_{k-1}) \qquad (57)
$$

Since $\mathbb{A}(x_{k-1}) = \emptyset$, $z^*(x_{k-1}) = -H^{-1}F^T x_{k-1}$. Then, $G_j z^*(x_{k-1}) \leq ||G_j H^{-1} F^T|| ||x_{k-1}||.$ In fact, $S_j x_k \geq$ $-||S_i|| ||x_k||$ and $||x_k - x_{k-1}|| \le ||x_k|| + ||x_{k-1}||$. Hence, the sufficient condition of (57) can be obtained as follows:

$$
w_j \ge \kappa ||G_j|| (||x_k|| + ||x_{k-1}||) + ||S_j|| ||x_k|| + ||G_j H^{-1} F^T || ||x_{k-1}||
$$

\n
$$
\ge c ||x_0|| \beta^k (\kappa ||G_j|| (1 + \beta^{-1}) + ||S_j|| + ||G_j H^{-1} F^T || \beta^{-1})
$$

\n
$$
\ge c ||x_0|| \beta^{\widehat{K}_2} (\kappa ||G_j|| (1 + \beta^{-1}) + ||S_j|| + ||G_j H^{-1} F^T || \beta^{-1})
$$

\n
$$
\ge 0.
$$

where the second inequality follows from Assumption [2.](#page-6-10) Since $w > 0$, the sufficient condition holds for any $j \in \mathbb{N}_{[1,n_c]}$. As a result, $\mathbb{D}(x_k) = \mathbb{N}_{[1,n_c]}$. To sum up, $|\mathbb{I}(x_k)| = 0$.

Zhinan Hou received the B.S. degree in Control Science and Engineering at the Department of Automation, Tsinghua University, Beijing, China, in 2022, where he is currently working toward the Ph.D. degree. His research interests include model predictive control, multiparametric quadratic program.

Keyou You received the B.S. degree in Statistical Science from Sun Yat-sen University, Guangzhou, China, in 2007 and the Ph.D. degree in Electrical and Electronic Engineering from Nanyang Technological University (NTU), Singapore, in 2012. After briefly working as a Research Fellow at NTU, he joined Tsinghua University in Beijing, China where he is now a Full Professor in the Department of Automation. He held visiting positions at Politecnico di Torino, Hong Kong University of Science and Technology, University of Melbourne and etc.

Prof. You's research interests focus on the intersections between control, optimization and learning as well as their applications in autonomous systems. He received the Guan Zhaozhi award at the 29th Chinese Control Conference in 2010 and the ACA (Asian Control Association) Temasek Young Educator Award in 2019. He received the National Science Funds for Excellent Young Scholars in 2017, and for Distinguished Young Scholars in 2023. Currently, he is an Associate Editor for *Automatica* , *IEEE Transactions on Control of Network Systems*, and *IEEE Transactions on Cybernetics* .
