Abstract

Learning the Individual Treatment Effect (ITE) is essential for personalized decision making, yet causal inference has traditionally focused on aggregated treatment effects. While integrating conformal prediction with causal inference can provide valid uncertainty quantification for ITEs, the resulting prediction intervals are often excessively wide, limiting their practical utility. To address this limitation, we introduce Surrogate-assisted Conformal Inference for Efficient Individual Causal Effects (SCIENCE), a framework designed to construct more efficient prediction intervals for ITEs. SCIENCE applies to various data configurations, including semi-supervised and surrogate-assisted semi-supervised learning. It accommodates covariate shifts between source data, which contain primary outcomes, and target data, which may include only surrogate outcomes or covariates. Leveraging semi-parametric efficiency theory, SCIENCE produces rate double-robust prediction intervals under mild rate convergence conditions, permitting the use of flexible non-parametric models to estimate nuisance functions. We quantify efficiency gains by comparing semi-parametric efficiency bounds with and without the incorporation of surrogates. Simulation studies demonstrate that our surrogate-assisted intervals offer substantial efficiency improvements over existing methods while maintaining valid group-conditional coverage. Applied to the phase 3 Moderna COVE COVID-19 vaccine trial, SCIENCE illustrates how multiple surrogate markers can be leveraged to generate more efficient prediction intervals.

Keywords: Conformal inference, Individual causal effects, Personalized medicine, Semi-supervised inference, Surrogate outcomes

1 Introduction

Personalized medicine emphasizes the need for precise learning of individual treatment effects (ITEs) to guide patient-level decision-making. A central challenge in causal inference is the fundamental problem of missing data – only one potential outcome is observed for each individual, while the others remain unobserved (Holland, 1986), rendering the ITE only partially identified. As a result, causal inference has traditionally focused on estimands like the average treatment effect (ATE) and the conditional average treatment effect (CATE), which provide insights at the population or subgroup level by averaging across individuals. However, these coarsened estimates may fail to capture individual-level heterogeneity that is critical for clinical decisions, especially for individuals who may respond differently to treatment. This limitation is evident in contexts such as vaccine efficacy studies, where personalized vaccine recommendations are useful for guiding individual decisions. Two examples are the estimates for vulnerable immunocompromised individuals with a wide diversity of immunocompromised conditions, and estimates based on levels of antibodies against the targeted pathogen.

In such settings, surrogate outcomes – biological markers, intermediate variables, or machine-learning-derived predictions that are easier to observe than the primary outcomes – offer a promising avenue for improving the estimation of causal effects. Surrogate outcomes can often predict the primary outcome with reasonable accuracy and have been shown to enhance the efficiency of causal estimates, especially when the primary outcome is missing for a large proportion of individuals, e.g., the primary outcome may be invasive, costly, or take a long time to measure for many individuals. In vaccine studies, for instance, immune correlates of protection, such as neutralizing antibody titers, are now used as validated surrogates to predict vaccine efficacy for some contexts of use (Gilbert, Montefiori, McDermott, Fong, Benkeser, Deng, Zhou, Houchens, Martins, Jayashankar et al., 2022; Gilbert, Donis, Koup, Fong, Plotkin and Follmann, 2022). Despite these advantages, current statistical methods have yet to incorporate surrogate outcomes to enhance *individual-level* causal inference. Our work addresses this gap by incorporating surrogate outcomes – without imposing stringent conditions on their validity – into a conformal inference framework. This approach enables more efficient uncertainty quantification of ITEs, advancing

statistical theory and machine learning techniques in personalized medicine applications.

1.1 Related literature on surrogates outcomes

Since Prentice (1989) first proposed a definition and operational criterion for statistical surrogacy, several frameworks have been introduced for surrogate evaluation, including causal mediation (Robins and Greenland, 1992), principal stratification (Frangakis and Rubin, 2002), the proportion of treatment effect explained (Freedman et al., 1992; Parast et al., 2016; Wang, Parast, Tian and Cai, 2020; Price et al., 2018; Han et al., 2022; Wang et al., 2023; Gilbert et al., 2024), and the meta-analytic framework (Buyse et al., 2000; Burzykowski et al., 2005). Joffe and Greene (2009) and Conlon et al. (2017) characterized these methods broadly into the causal effects (Gilbert and Hudgens, 2008) and causal association (Li et al., 2010; Alonso et al., 2016) frameworks. For a comprehensive overview of surrogate evaluation methods in clinical trials, including recent developments, see Elliott (2023). This line of work aims to identify and validate surrogate outcomes as replacements for primary outcomes, enabling traditional or provisional approval of treatments through surrogate-based endpoints in clinical trials. Surrogate endpoint validation allows regulatory agencies, like the FDA, to accelerate approval processes for critical illnesses by relying on surrogate markers in place of target endpoints (FDA, 1992; 2021). However, surrogate markers are not always reliable; for example, drugs approved based on arrhythmia suppression (as a surrogate for mortality) later showed increased mortality in follow-up trials (Fleming and DeMets, 1996). To mitigate such risks, a range of surrogate validation criteria have been proposed, but these often impose stringent, untestable assumptions, such as the strong statistical surrogate assumption (Prentice, 1989) to fuse the target and source datasets, as in Athey et al. (2019).

In our approach, we avoid imposing such strict conditions, viewing surrogates as auxiliary information for the primary outcome rather than replacements. Our work builds upon a parallel line of work that focuses on utilizing surrogate outcomes to enhance the efficiency of treatment effect estimation on long-term or primary outcomes. Athey et al. (2020) are motivated by combining experimental and observational data to estimate long-term treatment effects, where the experimental data includes only surrogates but the observational

data includes surrogates and primary outcomes. Chen and Ritzwoller (2023) studied semiparametric inference of the ATE in the settings considered by Athey et al. (2020) and derived semiparametric efficiency bounds. Cheng et al. (2021) and Kallus and Mao (2020) studied efficient ATE estimation when combining a small number of primary outcome observations with many observations of the surrogates, without assuming strong statistical surrogacy. Imbens et al. (2024) explored the sequential structure of multiple surrogates and identified the average treatment effect on the primary outcomes in the presence of unmeasured confounders.

1.2 Related literature on prediction-powered inference

There is a growing literature on using black-box machine learning predictions as “noisy surrogates” for the true outcome (Wang, McCormick and Leek, 2020). One recent popular method is prediction-powered inference (PPI) (Angelopoulos, Bates, Fannjiang, Jordan and Zrnic, 2023), which uses a small amount of gold standard labels and a large number of arbitrary machine learning predictions as surrogates. However, Angelopoulos, Duchi and Zrnic (2023) showed that when the surrogates are inaccurate, the PPI interval can be worse than the standard interval using only the labeled data and proposed a fix called PPI++. Miao et al. (2023) showed that the PPI estimator is in general not statistically efficient and proposed an efficient influence function-based estimator. Gan and Liang (2023) propose an alternative estimator that is guaranteed to be asymptotically no worse than the supervised counterpart and is equivalent to PPI++ (Angelopoulos, Duchi and Zrnic, 2023) for a one-dimensional parameter. The general strategy in all of these works is to augment an estimator with an unbiased estimator of zero, leveraging its correlation with the estimation error to improve precision – a well-established approach in missing data and semiparametric efficiency theory (Bickel et al., 1993; Robins et al., 1994; 1995; Hahn, 1998). Our work is connected to PPI in the sense that our proposed method can leverage machine-learned predictions as surrogates just as easily as it can use a validated surrogate, since we require no conditions on statistical surrogacy. The extent of efficiency gain will depend on the accuracy of the machine-learned prediction for the primary outcome.

However, all of these works, whether leveraging surrogate outcomes or machine-learned

predictions as noisy surrogates, remain limited to population-level treatment effects, and it is not obvious how one could extend these methods to target the ITE. As a result, while surrogates have been shown to improve ATE estimation, their potential to enhance individual-level causal inference remains unexplored.

1.3 Related literature on conformal inference of counterfactuals

Recent advances in conformal inference have shown promise in addressing the challenges of ITE estimation. Lei and Candès (2021) provided the first connection between conformal prediction and causal inference, introducing a methodology to construct prediction sets for counterfactuals and ITEs. Yang et al. (2024) reformulated the prediction problem under covariate shift into a missing data problem and provided doubly robust and computationally efficient methods leveraging modern semiparametric efficiency theory. However, the prediction intervals produced for ITEs are typically too wide to be useful in practice. Neither of these works explores how incorporating surrogate outcomes could enhance the efficiency of the prediction intervals.

1.4 Contributions

In this paper, we make several key contributions from both statistical and scientific perspectives. We consider different data configurations corresponding to the semi-supervised setting (Setting 1), the surrogate-assisted semi-supervised setting (Setting 2), and an intermediary setting where surrogates are observed in the source data only (Setting 3). In each setting, we derive the semi-parametric efficiency bounds for estimating the quantile of the non-conformity score, which is a necessary ingredient in constructing conformal prediction intervals (Theorems 2 and 4) and establish the desired Probably Approximately Correct (PAC) asymptotic coverage (Theorem 3). Moreover, we analytically quantify the efficiency gains from observing surrogates and find that leveraging surrogates is beneficial when surrogates are reasonably predictive of the primary outcome (Corollaries 1 and 2).

From a methodological viewpoint, the proposed SCIENCE framework provides valid uncertainty quantification for causal estimands of interest, such as Individual Treatment Effects (ITEs), and more generally for any marginal contrast of the individual potential

outcomes. The prediction intervals produced by SCIENCE are valid under minimal assumptions, offering both marginal coverage and group-conditional coverage guarantees. This ensures that the intervals are reliable not just on average but also across subpopulations. Furthermore, such asymptotic coverage is guaranteed for both the source data, where primary outcomes (i.e., one of the potential outcomes) are observed, and the target data, where primary outcomes are missing. By employing semiparametric efficiency theory and using cross-fitting (Chernozhukov et al., 2018), we allow for the use of any flexible machine learning estimators for estimating nuisance parameters, as long as they satisfy some generic convergence rate conditions. This approach enables us to achieve rate double robustness under relatively mild assumptions.

Our approach is validated through extensive simulations for both continuous and discrete outcomes, demonstrating significant efficiency gains in terms of shorter, more informative prediction intervals. An open-source R package is available for implementing our proposed methodology at <https://github.com/Gaochenyin/SurrConformalDR>. We analyze the phase 3 Moderna COVE COVID-19 vaccine efficacy trial, illustrating that incorporating surrogate markers, such as neutralizing and binding antibody levels at an early time point, leads to more efficient prediction intervals. This analysis highlights the practical advantages of our methods in enhancing individual-level efficacy assessments.

2 Preliminaries

2.1 Notation

We consider a causal inference framework where individuals receive one of two treatments: $A \in \{0, 1\}$ representing for example a vaccine ($A = 1$) or a placebo ($A = 0$). Let $X \in \mathcal{X} \subseteq \mathbb{R}^{d_x}$ denote the vector of baseline covariates, such as patient demographics and clinical characteristics. The primary outcome of interest is denoted $Y \in \mathbb{R}$, which could be quantitative or discrete, such as a clinical endpoint like acquisition of symptomatic SARS-CoV-2 infection. Additionally, some individuals could have surrogate outcomes $S \in \mathcal{S} \subseteq \mathbb{R}^{d_s}$ measured, such as biomarkers (e.g., neutralizing antibody titers), that may be predictive of the primary outcome.

Under the potential outcomes framework, we define $Y(a)$ and $S(a)$ as the potential primary outcome and surrogate outcome, respectively, that would be observed if an individual were assigned treatment $A = a$. We assume that each individual receives the treatment assigned in the study, so the observed outcomes are $(Y, S) = (Y(A), S(A))$. This assumption implies consistency and no interference between individuals; that is, one individual’s treatment assignment does not affect another individual’s outcomes. In certain contexts, such as vaccine studies, interference may occur. For example, the vaccination status of one individual could influence the infection risk of others through spillover effects (Hudgens and Halloran, 2008; Tchetgen and VanderWeele, 2012). Although important, this work will not address settings with interference.

We denote the units with observed primary outcomes as the source data and those without as the target data. Let $D \in \{0, 1\}$ be an indicator of the data origin, with $D = 1$ representing source data and $D = 0$ representing target data. In summary, we observe a source dataset $\{(X_i, A_i, S_i, Y_i, D_i = 1) : i \in \mathcal{I}^s\}$ and a target dataset $\{(X_i, A_i, S_i, Y_i = \text{NA}, D_i = 0) : i \in \mathcal{I}^t\}$, where NA means “not available” (missing), and \mathcal{I}^s and \mathcal{I}^t are the index sets for the source and target data, respectively. We denote $n_{D1} = |\mathcal{I}^s|$ and $n_{D0} = |\mathcal{I}^t|$ as the sample sizes for the two datasets, and $N = n_{D1} + n_{D0}$ as the total sample size. We assume that each data point $\mathcal{O}_i = (X_i, A_i, S_i, Y_i, D_i)$ is generated by coarsening an independent and identically distributed draw from a population $\mathcal{O}^* = (X, A, S(0), S(1), Y(0), Y(1), D)$ with an underlying joint distribution \mathbb{P} . The coarsening mechanism can be described by the map:

$$\mathcal{C} : (X, A, S(0), S(1), Y(0), Y(1), D) \rightarrow (X, A, S(A), D \cdot Y(A) + (1 - D) \cdot \text{NA}, D).$$

Regular arithmetic operations apply to missing values, such that $D \cdot Y(A) + (1 - D) \cdot \text{NA}$ is $Y(A)$ for source data ($D = 1$) and NA for target data ($D = 0$).

2.2 Problem settings

The semi-supervised setting (Setting 1) is considered as a baseline setting in which we observe X, A, Y on units in the source data but only observe X, A on units in the target

data. The same data configuration was considered in Zhang and Bradic (2022) for semi-supervised estimation of heterogeneous treatment effects. In the context of transporting ATEs from a completed trial (source data) to a new population (target data), Dahabreh et al. (2020) considered a slightly modified data configuration where the target data has only information on X (rather than X, A).

We then consider the surrogate-assisted semi-supervised setting (Setting 2), in which we observe X, A, S, Y on units in the source data but only observe X, A, S on units in the target data. Compared to Setting 1, we additionally observe S on all units. The same data configuration was considered in Kallus and Mao (2020) and Cheng et al. (2021) in the context of estimation of ATEs. Setting 2 represents a common application of a sufficiently-validated surrogate endpoint: bridging approval of a treatment $A = 1$ with efficacy established from a completed phase 3 randomized trial with X, A, S, Y measured (source data), to a new study population whose features may be shifted; for vaccines this widespread application is *immunobridging* (Krause et al., 2022). The target dataset for the new population is a randomized trial with the surrogate S used as the primary endpoint for the purpose of inferring a sufficient treatment effect on Y for the target population. Immunobridging has been applied extensively for many vaccines, including for mRNA COVID-19 vaccines, for example for bridging efficacy against COVID-19 from adults to children (Walter et al., 2022).

Finally, we consider an intermediate setting where X, A, S, Y is observed in the source data, but only X, A is available in the target data (Setting 3). We compare this setting to the baseline setting without surrogates (Setting 1) in terms of the semiparametric efficiency lower bounds. Our analysis reveals that the efficiency lower bounds coincide under these two settings (Theorem 2), meaning that when surrogates are observed only in the source data where primary outcomes are already available, they do not improve the efficiency for constructing the prediction intervals for the target data.

3 Conformal inference under covariate shift

3.1 General framework

Conformal inference is a powerful statistical framework for providing rigorous uncertainty quantification on individual predictions. Given independent and identically distributed source data (W_i, Y_i) for $i = 1, \dots, N$, drawn from a source distribution $P_W \otimes P_{Y|W}$, where $W_i = (X_i, S_i) \in \mathcal{W}$ if surrogates S_i are available, or $W_i = X_i$ otherwise, and a desired nominal coverage rate $1 - \alpha \in (0, 1)$, our goal is to construct prediction intervals $C(W)$ satisfying

$$P_{(W_f, Y_f) \sim Q_W \otimes P_{Y|W}}(Y_f \in C(W_f)) \geq 1 - \alpha,$$

where the pair (W_f, Y_f) is drawn from the target distribution $Q_W \otimes P_{Y|W}$ and the probability is taken over the marginal distribution of the source data and the future observation (X_f, Y_f) .

Here, Q_W may differ from P_W , a scenario referred to as covariate shift when $W = X$ (Sugiyama et al., 2007). In our context where $W = (X, S)$, the joint distribution of covariates and surrogates can differ between the source and target datasets. If one is interested in a subset of the population where W_f belongs to a subset $\mathcal{A}_W \subset \mathcal{W}$, the target distribution becomes $Q_W = P_{W|\mathcal{A}_W}$. In general, we can construct prediction intervals with valid group-conditional coverage by defining the target population as a specific subset characterized by \mathcal{A}_W .

The prediction intervals $C(W)$ are determined by a one-dimensional function of W ,

denoted by $C(W; r_\alpha)$, and are constructed based on a non-conformity score $R(w, y)$. This score is a fixed non-stochastic function referred to as the non-conformity score (Vovk et al., 2005). For example, $R(w, y)$ can be the regression residual $R(w, y) = |y - \widehat{E}(y | w)|$ (Lei et al., 2018) or $R(w, y) = \max\{\widehat{q}_{\alpha/2}(w) - y, y - \widehat{q}_{1-\alpha/2}(w)\}$, i.e., the conformalized quantile residual with estimated conditional quantiles $\widehat{q}_{\alpha/2}(\cdot)$ and $\widehat{q}_{1-\alpha/2}(\cdot)$ (Romano et al., 2019). Specifically, for each value of W and a threshold r_α , the prediction interval is defined as $C(W; r_\alpha) = \{y \in \mathcal{Y} \mid R(W, y) \leq r_\alpha\}$. Given this definition, the event that the future response Y_f falls within the prediction interval $C(W_f; r_\alpha)$ is equivalent to the event that the non-conformity score $R(W_f, Y_f)$ is below r_α , and their probabilities under the joint distribution $Q_W \otimes P_{Y|W}$ are equal:

$$P_{(W_f, Y_f) \sim Q_W \otimes P_{Y|W}}(Y_f \in C(W_f; r_\alpha)) = P_{(W_f, Y_f) \sim Q_W \otimes P_{Y|W}}(R(W_f, Y_f) \leq r_\alpha).$$

If r_α is the smallest $(1 - \alpha)$ -quantile of $R(W_f, Y_f)$ for the target distribution $Q_W \otimes P_{Y|W}$, we have

$$P_{(W_f, Y_f) \sim Q_W \otimes P_{Y|W}}(R(W_f, Y_f) \leq r_\alpha) \geq 1 - \alpha,$$

which holds irrespective of the choice of function $R(x, y)$. Therefore, our goal is to estimate the $(1 - \alpha)$ -quantile of $R(W_f, Y_f)$ from the source data following the distribution $P_W \otimes P_{Y|W}$ while $(W_f, Y_f) \sim Q_W \otimes P_{Y|W}$.

3.2 Reformulation for individualized causal effects

In this section, we first assume that the causal estimand θ_i does not depend on the joint distribution of potential outcomes, which allows us to reformulate the covariate shift problem for the general conformal inference into the missing data framework, as seen in Yang et al. (2024).

Assumption 1. *Assume the individual causal estimand $\theta_i = f(Y_i(1), Y_i(0))$ is a marginal contrast estimand, where θ_i can be completely characterized as a pre-specified transformation of the potential outcomes $Y_i(1)$ and $Y_i(0)$ separately, i.e., $\theta_i = u(Y_i(1)) - u(Y_i(0))$.*

This class of transformations encompasses a wide range of estimands, including the

ITE $Y(1) - Y(0)$ and the risk ratio under the logarithmic scale $\log(Y(1)) - \log(Y(0))$ for continuous outcomes. For ordinal outcomes, transformations $u(\cdot)$ can correspond to utility scores assigned to each level, often based on scientific domain knowledge, as observed in some stroke trials (Chaisinanunkul et al., 2015; Nogueira et al., 2018).

Next, the constructed prediction intervals $C_\theta(W_i; r_\alpha)$ for θ_i should satisfy:

$$P\{\theta_i \in C_\theta(W_i; r_\alpha)\} = P(D_i = 1)P(\theta_i \in C_\theta(W_i; r_\alpha) \mid D_i = 1) \quad (1)$$

$$+ P(D_i = 0)P(\theta_i \in C_\theta(W_i; r_\alpha) \mid D_i = 0). \quad (2)$$

For the term (1), where one of the potential primary outcomes $Y(A)$ is observed for $D = 1$, we only need to construct the prediction intervals for the counterfactuals $u\{Y(0)\}$ when $A = 1$ and $u\{Y(1)\}$ when $A = 0$:

$$\begin{aligned} & P(\theta_i \in C_\theta(W_i; r_\alpha) \mid D_i = 1) \\ &= P(A_i = 1 \mid D_i = 1)P\{u\{Y_i(0)\} \in C_0(W_i; r_{\alpha,0}) \mid A_i = 1, D_i = 1\} \\ &+ P(A_i = 0 \mid D_i = 1)P\{u\{Y_i(1)\} \in C_1(W_i; r_{\alpha,1}) \mid A_i = 0, D_i = 1\} \\ &= P(A_i = 1 \mid D_i = 1)P(R_{0,i} \leq r_{\alpha,0} \mid A_i = 1, D_i = 1) \end{aligned} \quad (3)$$

$$+ P(A_i = 0 \mid D_i = 1)P(R_{1,i} \leq r_{\alpha,1} \mid A_i = 0, D_i = 1), \quad (4)$$

where $r_{\alpha,a} = \inf\{r : F_{R_a}(r \mid A = 1 - a, D = 1) \geq 1 - \alpha\}$ is the $(1 - \alpha)$ -quantile of the non-conformity score $R_{a,i} = R(W_i, u_a\{Y_i(a)\})$ conditional on $A = 1 - a$ and $D = 1$. To connect it with the general conformal inference framework, the target distribution is $P(W, Y(a) \mid A = 1 - a, D = 1)$, while the training data is distributed by $P(W, Y(a) \mid A = a, D = 1)$ as $Y(a)$ is only observed when $A = a, D = 1$; see Section 4 for more details.

For term (2), where both the potential primary outcomes are missing, our plan is to first create the data (W_i, C_i) by

$$C_i = \begin{cases} u(Y_i) - C_0(W_i; r_{\alpha,0}), & A_i = 1, D_i = 1 \\ C_1(W_i; r_{\alpha,1}) - u(Y_i), & A_i = 0, D_i = 1, \end{cases}$$

where C_i is the prediction intervals for θ_i , which can be perceived as the pseudo-outcomes;

Next, a secondary conformal inference is performed on the left- and the right-end point of C_i to create the prediction intervals $C(W_i; r_{\gamma, C})$ satisfying:

$$P(C_i \subset C(W_i; r_{\gamma, C}) \mid D_i = 0) = P(R_{C,i} < r_{\gamma, C} \mid D_i = 0) \geq 1 - \gamma,$$

where $R_{C,i} = R(W_i, C_i)$ is the non-conformity score for the prediction intervals. Thus, the asymptotic coverage is guaranteed as $P(\theta_i \notin C(W_i; r_{\gamma, C}) \mid D_i = 0) \leq P(\theta_i \notin C_i \mid D_i = 0) + P(C_i \not\subset C(W_i; r_{\gamma, C}) \mid D_i = 0) \leq \alpha + \gamma$. To connect it with the general conformal inference framework, the target distribution is $P(W, C \mid D = 0)$ while the training data is distributed as $P(W, C \mid D = 1)$; see Section 5 for more details.

3.3 Assumptions

We require the following assumptions to ensure the identification of $r_{\alpha, a}$ and $r_{\gamma, C}$.

Assumption 2. *There exists some constant $0 < c_0 < 1/2$ such that $c_0 \leq P(A = 1 \mid x) \leq 1 - c_0$, $c_0 \leq P(D = 1 \mid x, a) \leq 1 - c_0$ for $a = 0, 1$ and any x such that $f(x) > 0$.*

Assumption 2 states that each individual should have a probability of at least c_0 of being assigned to treatment or being included in the target data, conditional on any covariates with a positive likelihood of occurrence. This overlap assumption is common in the causal inference and missing data literature (Imbens and Rubin, 2015). In practice, this condition prevents situations where only certain types of individuals are treated or included in the target data, thereby enabling comparisons across treatments and datasets.

Assumption 3. *$A \perp \{Y(a), S(a)\} \mid X$ for $a = 0, 1$.*

Assumption 3 states that, conditional on the observed covariates X , the treatment assignment A is independent of the potential primary outcomes $Y(a)$ and surrogates $S(a)$ for each treatment level a in the combined data. This assumption is commonly referred to as unconfoundedness or ignorability of treatment assignment (Kallus and Mao, 2020).

Assumption 4. *$D \perp S(a) \mid X, A$ for $a = 0, 1$.*

Assumption 4 states that the data origin indicator D does not depend on the surrogates $S(a)$, given the observed variables X and A . Therefore, the surrogates from combined data (if available) can be leveraged for efficiency gain.

Assumption 5. $D \perp Y(a) \mid S(a), X, A$ for $a = 0, 1$.

Assumption 5 states that the data origin indicator D is conditionally independent of the potential primary outcomes $Y(a)$ given the observed covariates X , the potential surrogate $S(a)$, and treatment assignment A . Since D is equivalent to an indicator that $Y(a)$ is missing or not, Assumption 5 can be referred to as the missing at random (MAR) assumption in the missing data literature (Little and Rubin, 2019), which implies that the observed variables fully explain any missingness in the primary outcomes. This is useful because it allows us to use the source data to infer information about the missing primary outcome in the target data, even in the presence of potential distributional shifts between data sources. Therefore, this condition is weaker than the missing completely at random (MCAR) condition assumed in the semi-supervised inference literature (Cheng et al., 2021; Zhang and Bradic, 2022), since it does not allow missingness to depend on any other variables.

Below, we show that our assumptions are related to a similar set of identification assumptions in Athey et al. (2020).

Lemma 1. *Under Assumptions 1 to 5, we have (a) $D \perp \{Y(a), S(a)\} \mid X$, (b) $A \perp \{Y(a), S(a)\} \mid X, D = 0$, and (c) $A \perp \{Y(a), S(a)\} \mid X, D = 1$ for $a = 0, 1$.*

To align our problem setting with that in Athey et al. (2020), we could re-label our source data ($D = 1$) as their observational data and our target data ($D = 0$) as their experimental data. Then, Lemma 1 recovers the identification assumptions in Athey et al. (2020). In particular, Condition (a) corresponds to their external validity, and Condition (b) corresponds to their internal validity for the experimental data. Condition (c) is similar to their latent unconfoundedness for the observational data, i.e., $A \perp Y(a) \mid S(a), X, D = 1$. Our assumptions additionally require unconfoundedness for the surrogates of the observational data, i.e. $A \perp S(a) \mid X, D = 1$. This requirement is necessary to identify the non-conformity score $r_{\alpha, a}$ for $D = 1$ in (1). Since Athey et al. (2020) primarily focuses on the identification across the combined population, this additional unconfoundedness

condition is not necessary for their identification purposes; see Figure 1 for a single world intervention graph for illustration.

Figure 1: Single-world intervention graph for the source and target data with surrogates. Here, the shaded nodes, confounder U and primary outcome $Y(a)$ of the target data, are unobserved. The dashed lines, that the unobserved confounder U could affect treatment A and surrogates $S(a)$ of the source data, are permitted in Athey et al. (2020) but are not allowed for our problem setup.

4 Conformal inference on the source data

4.1 Identification

Theorem 1. (*Identification formulas*). *Under Assumptions 1 to 5, we have*

$$\begin{aligned} 1 - \alpha &= P(R_a < r_{\alpha,a} \mid A = 1 - a, D = 1) \\ &= E_W\{P_Y(R_a < r_{\alpha,a} \mid A = a, D = 1, W) \mid A = 1 - a, D = 1\}. \end{aligned}$$

Thus, the identification formulas under Settings 1 – 3 can be obtained accordingly:

(Setting 1)

$$1 - \alpha = E_X\{P_Y(R_a < r_{\alpha,a} \mid A = a, D = 1, X) \mid A = 1 - a, D = 1\},$$

(Setting 2)

$$\begin{aligned} 1 - \alpha &= E_W\{P_Y(R_a < r_{\alpha,a} \mid A = a, D = 1, W) \mid A = 1 - a, D = 1\} \\ &= E_X[E_S\{P_Y(R_a < r_{\alpha,a} \mid A = a, D = 1, S, X) \mid A = a, X\} \mid A = 1 - a, D = 1], \end{aligned}$$

(Setting 3)

$$\begin{aligned} 1 - \alpha &= E_W\{P_Y(R_a < r_{\alpha,a} \mid A = a, D = 1, W) \mid A = 1 - a, D = 1\} \\ &= E_X[E_S\{P_Y(R_a < r_{\alpha,a} \mid A = a, D = 1, S, X) \mid A = a, D = 1, X\} \mid A = 1 - a, D = 1] \\ &= E_X\{P_Y(R_a < r_{\alpha,a} \mid A = a, D = 1, X) \mid A = 1 - a, D = 1\}. \end{aligned}$$

The identification formula under Setting 3 reduces to the one under Setting 1, where the surrogates S can only be leveraged for $D = 1$, since they are missing for $D = 0$.

4.2 Semi-parametric efficiency analysis

In this section, we derive the efficient influence functions (EIFs) for $r_{\alpha,1}$ under Settings 1 – 3, and assess the potential efficiency gains from incorporating surrogates. The derivations for the EIFs of $r_{\alpha,0}$ follow analogously and are presented in Section A.6 of the Supplementary Materials. Key necessary model definitions are summarized in Table 4.

Theorem 2. *Under Assumptions 1 to 5, the EIF $\psi_1^{(j)}$ for $r_{\alpha,1}$ under Setting j , for $j = S1, S2, S3$, is given, up to a proportionality constant, by*

$$\begin{aligned} \psi_1^{(S1)}(r_{\alpha,1}, W; m, e_D, \pi_A) &= \psi_1^{(S3)}(r_{\alpha,1}, W; m, e_D, \pi_A) = D(1 - A)\{m_1(r_{\alpha,1}, X) - (1 - \alpha)\} \\ &\quad + \frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}\{\mathbf{1}(R_1 < r_{\alpha,1}) - m_1(r_{\alpha,1}, X)\}, \end{aligned}$$

Table 4: Lists of model definitions and details

Model	Definition
$e_A(X) = P(A = 1 X)$	propensity score for treatment
$\pi_A(X) = \{1 - e_A(X)\}/e_A(X)$	inverse odds of treatment assignment
$e_D(X) = P(D = 1 X)$	propensity score for observing primary outcomes
$e_D(X, A) = P(D = 1 X, A)$	propensity score for observing primary outcomes within each group
$\pi_D(X) = \{1 - e_D(X)\}/e_D(X)$	inverse odds of observing primary outcomes
$\tilde{m}_a(r, X, S)$ $= P(R_a < r X, S, A = a, D = 1)$	the conditional CDF of R_a at r with surrogates
$m_a(r, X)$ $= P(R_a < r X, A = a, D = 1)$	the conditional CDF of R_a at r without surrogates
$\tilde{m}_C(r, X, S)$ $= P(R_C < r X, S, D = 1)$	the conditional CDF of R_C at r with surrogates
$m_C(r, X)$ $= P(R_C < r X, D = 1)$	the conditional CDF of R_C at r without surrogates

and

$$\begin{aligned}
\psi_1^{(S2)}(r_{\alpha,1}, W; m, \tilde{m}, e_D, \pi_A) &= D(1 - A)\{m_1(r_{\alpha,1}, X) - (1 - \alpha)\} \\
&\quad + A\pi_A(X)e_D(X, 0)\{\tilde{m}_1(r_{\alpha,1}, X, S) - m_1(r_{\alpha,1}, X)\} \\
&\quad + \frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}\{\mathbf{1}(R_1 < r_{\alpha,1}) - \tilde{m}_1(r_{\alpha,1}, X, S)\}.
\end{aligned}$$

Theorem 2 reveals that the EIFs for Settings 1 and 3 are the same. This means that when there is no surrogate or primary outcome information in the target data, having access to surrogates in the source data does not improve the efficiency of estimating $r_{\alpha,1}$ when we already have access to the primary outcomes in the source data. Intuitively, the surrogates provide no extra information if they are only observed for the units that already have primary outcomes observed. Essentially, surrogates cannot enhance estimation efficiency unless they help impute missing primary outcomes. In contrast, when surrogates are observed in both the source and target data, they can be leveraged to predict the missing primary outcomes in the target data, potentially improving estimation efficiency.

Next, we formally quantify the efficiency gain in terms of the semi-parametric lower bounds from observing surrogates for both datasets as follows.

Corollary 1. *Under Assumptions 1 to 5, the efficiency gain from observing surrogates in both datasets (Setting 2) compared to only in the source data (Setting 1) in estimating $r_{\alpha,1}$*

is given by

$$V_1^{(S2)} - V_1^{(S1)} = E \left[\frac{1 - e_D(X, 1)}{e_D(X, 1)} \frac{e_D^2(X, 0) \{1 - e_A(X)\}^2}{e_A(X)} \text{var}\{\tilde{m}_1(r_{\alpha,1}, X, S) \mid X\} \right],$$

where $V_1^{(S1)} = \text{var}\{\psi_1^{(S1)}(r_{\alpha,1}, W; m, e_D, \pi_A)\}$ and $V_1^{(S2)} = \text{var}\{\psi_1^{(S2)}(r_{\alpha,1}, W; m, \tilde{m}, e_D, \pi_A)\}$.

Corollary 1 quantifies the efficiency gain in terms of the semiparametric efficiency lower bound for $r_{\alpha,1}$. Specifically, the efficiency gain depends on the predictiveness of surrogates for the primary outcomes. This is measured by the variance $\text{var}\{\tilde{m}_1(r_{\alpha,1}, X, S) \mid X\} = \text{var}\{P(R_1 < r_{\alpha,1} \mid X, S, A = 1, D = 1) \mid X\}$, which reflects the additional variability in predicting R_1 that is captured by the surrogates S beyond the covariates X . A higher variance means surrogates provide substantial information about the primary outcome, leading to greater efficiency gains when estimating $r_{\alpha,1}$.

Furthermore, the efficiency gain in estimating $r_{\alpha,1}$ is more pronounced when the proportion of primary outcomes observed is large for the control group but small for the treatment group. Intuitively, a higher proportion of primary outcomes observed in the treatment group indicates less missingness to address when estimating $r_{\alpha,1}$, leading to less room for extra efficiency gain from leveraging surrogates. On the other hand, a higher proportion in the control group could amplify the efficiency gain by targeting a larger population as in (4). As expected, the efficiency gain should be affected differently by $e_D(X, 0)$ and $e_D(X, 1)$ when estimating $r_{\alpha,0}$ (Corollary A.1). Thus, reasonable gains in efficiency in estimating θ_i can be expected in settings with moderate levels of missingness for control and treatment groups.

4.3 Implementation details

To construct the semi-parametric efficient estimators for $r_{\alpha,a}$, we adopt the split conformal inference strategy (Lei and Wasserman, 2014), which randomly splits the combined data into two folds, \mathcal{I}_1 and \mathcal{I}_2 . The learning algorithms (e.g., the nuisance functions) are trained on the first fold, \mathcal{I}_1 , while the prediction intervals are constructed using non-conformity scores on the second fold, \mathcal{I}_2 . Details of the split conformal inference strategy are summarized in Figure 2 for illustration.

Figure 2: Schematic illustration for implementation of split conformal inference

For concreteness, we describe split conformal inference for $Y(a)$ using conformalized quantile residuals (CQR) on the source data. The implementation on the target data follows analogous logic. Let $\hat{q}_{\alpha/2,a}(\cdot)$ and $\hat{q}_{1-\alpha/2,a}(\cdot)$ be the quantile models for the primary outcomes $Y(a)$ trained on the first fold \mathcal{I}_1 with $A = a$. Additionally, the nuisance functions \hat{e}_A and \hat{e}_D are estimated on the first data fold, \mathcal{I}_1 . To alleviate the computational burden of learning the entire conditional distribution $m_a(r, X)$ and $\tilde{m}_a(r, X)$ for infinitely many r , we adopt the localized debiased machine learning approach (Kallus et al., 2024), where the first data fold, \mathcal{I}_1 , is further divided into two sub-folds, \mathcal{I}_{11} and \mathcal{I}_{12} . The first sub-fold, \mathcal{I}_{11} , is used to construct an initial estimator $\hat{r}_{\alpha,a}^{\text{init}}$ for $r_{\alpha,a}$. A natural initial estimator could be the weighted split-CQR estimator in Lei and Candès (2021). Then, the second sub-fold, \mathcal{I}_{12} , is used to estimate the nuisance functions $\hat{m}_a(\hat{r}_{\alpha,a}^{\text{init}}, X)$ and $\hat{\tilde{m}}_a(\hat{r}_{\alpha,a}^{\text{init}}, X, S)$ with any machine learning binary algorithm based on this single initial estimator $\hat{r}_{\alpha,a}^{\text{init}}$.

Next, the non-conformity scores R_a are evaluated on the second fold, \mathcal{I}_2 , with the estimated quantile models $\hat{q}_{\alpha/2,a}(\cdot)$ and $\hat{q}_{1-\alpha/2,a}(\cdot)$ as $R_{a,i} = \mathbf{1}(A_i = a) \max\{\hat{q}_{\alpha/2,a}(W_i) - Y_i, Y_i - \hat{q}_{1-\alpha/2,a}(W_i)\}$. Finally, we find the semi-parametric efficient estimators $\hat{r}_{\alpha,a}^{(S1)}$ and $\hat{r}_{\alpha,a}^{(S2)}$ on \mathcal{I}_2 , defined as the smallest values satisfying

$$\sum_{i \in \mathcal{I}_2} \psi_a^{(S1)}(\hat{r}_{\alpha,a}^{(S1)}, W_i; \hat{m}, \hat{e}_D, \hat{\pi}_A) \geq 0, \quad \sum_{i \in \mathcal{I}_2} \psi_a^{(S2)}(\hat{r}_{\alpha,a}^{(S2)}, W_i; \hat{m}, \hat{\tilde{m}}, \hat{e}_D, \hat{\pi}_A) \geq 0$$

where \hat{m} , $\hat{\tilde{m}}$, \hat{e}_D , and $\hat{\pi}_A$ are estimated from the first data fold \mathcal{I}_1 .

4.4 Asymptotic properties for coverage

In this section, we establish asymptotic properties for the estimators of $r_{\alpha,1}$ and $r_{\alpha,0}$, which are important for constructing prediction intervals with the desired coverage level $1 - \alpha$. First, we establish the connection between the asymptotic coverage probability $P(R_a < r_{\alpha,a} \mid A = 1 - a, D = 1)$ and the EIF for $r_{\alpha,a}$.

Lemma 2. *Under Assumptions 1 to 5, the following holds for any EIF $\psi_a(r_{\alpha,a}, W)$ under Settings 1 – 3:*

$$P(R_a < r_{\alpha,a} \mid A = 1 - a, D = 1) = 1 - \alpha + \frac{E\{\psi_a(r_{\alpha,a}, W)\}}{P(A = 1 - a, D = 1)}.$$

Lemma 2 states that the asymptotic coverage probability deviates from the nominal level $1 - \alpha$ by a term proportional to the expected value of the EIF. We now list some regularity conditions for the nuisance functions that will be useful in establishing the asymptotic coverage probability for the estimators of $r_{\alpha,a}$:

(A1) The estimated functions $\hat{\pi}_A(X)$, $\hat{e}_D(X, A)$, $\hat{m}_a(r, X)$, and $\hat{\tilde{m}}_a(r, X, S)$ are bounded, i.e., $|\hat{\pi}_A(X)| \leq \pi_0$, $\underline{e}_0 \leq |\hat{e}_D(X, A)| \leq \bar{e}_0$, $|\hat{m}_a(r, X)| \leq m_0$, and $|\hat{\tilde{m}}_a(r, X, S)| \leq \tilde{m}_0$.

(A2) The estimators $\hat{m}_a(r, X)$ and $\hat{\tilde{m}}_a(r, X, S)$ are non-decreasing function of r .

Following the split conformal inference strategy in Section 4.3, the desired asymptotic coverage is guaranteed for the source data in Theorem 3.

Theorem 3. *Under Assumptions 1 to 5 and regularity conditions (A1) and (A2), there exist some constants C_0 and C_1 for any $\delta > 0$, such that*

$$\begin{aligned} & P(R_a \leq \hat{r}_{\alpha,a}^{(S_1)} \mid A_i = 1 - a, D_i = 1) \geq (1 - \alpha) \\ & - C_0 \frac{\pi_0 \bar{e}_0 \underline{e}_0^{-1} (1 + m_0)}{P(A = 1 - a, D = 1)} \sqrt{\frac{\log(1/\delta) + 1}{|\mathcal{I}_2|}} \\ & - C_1 \left\{ \frac{\|\hat{\pi}_A(X) - \pi_A(X)\|}{P(A = 1 - a, D = 1)} \cdot \sup_r \|\hat{m}_a(r, X) - m_a(r, X)\| \right. \\ & \left. + \frac{\|\hat{e}_D(X, A) - e_D(X, A)\|}{P(A = 1 - a, D = 1)} \cdot \sup_r \|\hat{\tilde{m}}_a(r, X) - m_a(r, X)\| \right\}, \end{aligned}$$

and

$$\begin{aligned}
& P(R_a \leq \widehat{r}_{\alpha,a}^{(S_2)} \mid A_i = 1 - a, D_i = 1) \geq (1 - \alpha) \\
& - C_0 \frac{\pi_0 \bar{e}_0 (\underline{e}_0^{-1} + m_0 + \underline{e}_0^{-1} \tilde{m}_0)}{P(A = 1 - a, D = 1)} \sqrt{\frac{\log(1/\delta) + 1}{|\mathcal{I}_2|}} \\
& - C_1 \left\{ \frac{\|\widehat{\pi}_A(X) - \pi_A(X)\|}{P(A = 1 - a, D = 1)} \cdot \sup_r \|\widehat{m}_a(r, X) - m_a(r, X)\| \right. \\
& + \frac{\|\widehat{e}_D(X, A) - e_D(X, A)\|}{P(A = 1 - a, D = 1)} \cdot \sup_r \|\widehat{m}_a(r, X) - m_a(r, X)\| \\
& \left. + \frac{\|\widehat{e}_D(X, A) - e_D(X, A)\|}{P(A = 1 - a, D = 1)} \cdot \sup_r \|\widehat{m}_a(r, X, S) - \tilde{m}_a(r, X, S)\| \right\}
\end{aligned}$$

hold with probability greater than $1 - \delta$.

Theorem 3 provides a coverage guarantee of $1 - \alpha$ for the prediction intervals of $u\{Y(1)\}$ and $u\{Y(0)\}$. Note that the slack for the coverage guarantee is the sum of two parts: the first part is induced by approximating the expectation with its empirical version, which scales as $O(N^{-1/2})$, by splitting the data into two folds \mathcal{I}_1 and \mathcal{I}_2 of similar size; the second part is induced by the product bias from the estimation of the nuisance functions, which is negligible if either $\|\widehat{\pi}_A(X) - \pi_A(X)\| + \|\widehat{e}_D(X, A) - e_D(X, A)\| = o_p(1)$ or $\sup_r \|\widehat{m}_a(r, X) - m_a(r, X)\| + \sup_r \|\widehat{m}_a(r, X, S) - \tilde{m}_a(r, X, S)\| = o_p(1)$. Such property is known as rate double robustness, which means that the asymptotic coverage is robust to small perturbations in the nuisance functions, such that their estimation errors affect the coverage error only in second-order terms (Chernozhukov et al., 2018).

Hence, the constructed prediction intervals $C_\theta(W_i; \widehat{r}_\alpha)$ by the SCIENCE framework achieve the desired coverage level asymptotically in the source data under Settings 1 to 3, up to a negligible term vanishing in probability:

$$\begin{aligned}
& P(\theta_i \in C_\theta(W_i; \widehat{r}_\alpha) \mid D_i = 1) \\
& = P(A_i = 1 \mid D_i = 1)P(R_0 \leq \widehat{r}_{\alpha,0} \mid A_i = 1, D_i = 1) \\
& + P(A_i = 0 \mid D_i = 1)P(R_1 \leq \widehat{r}_{\alpha,1} \mid A_i = 0, D_i = 1) \geq (1 - \alpha) + o_p(1),
\end{aligned}$$

which is often referred to as Probably Approximately Correct (PAC) coverage in the sta-

tistical literature (Krishnamoorthy and Mathew, 2009).

5 Conformal inference on the target data

In this section, we address the challenging task of constructing valid prediction intervals for the target data where primary outcomes are unobserved ($D = 0$). Building upon the nested conformal inference framework proposed by Lei and Candès (2021), we develop a two-step procedure to achieve this goal.

First, we generate a dataset (W_i, C_i) by constructing prediction intervals $C_i = C_\theta(W_i; r_\alpha)$ for each individual in the source data ($D = 1$). These intervals C_i are designed to cover the causal estimand θ_i with probability at least $1 - \alpha$ conditional on the source data, using the methods detailed in Section 4. Next, we treat the constructed intervals C_i as pseudo-outcomes and perform a secondary conformal inference to find a prediction interval $C(W; r_{\gamma, C})$ that nests C_i with high probability; $C(W; r_{\gamma, C})$ is called the nested prediction interval. Specifically, we aim to determine $r_{\gamma, C}$ such that

$$P(C_i \subset C(W_i; r_{\gamma, C}) \mid D_i = 0) = P(R_{C,i} \leq r_{\gamma, C} \mid D_i = 0) = 1 - \gamma, \quad (5)$$

where $R_{C,i} = R(W_i, C_i)$ is the non-conformity score measuring the discrepancy between the pseudo-outcome C and its prediction based on W . This approach accounts for the uncertainty in the pseudo-outcomes and allows us to construct prediction intervals for the target data where primary outcomes are missing. Figure 3 provides a schematic illustration of this nested procedure, and an example of constructing R_C is given in Remark 1.

Remark 1. Consider the causal estimand as the ITE, $\theta_i = Y_i(1) - Y_i(0)$. For the source data $D = 1$, we construct prediction intervals $C_i = C_\theta(W_i; r_\alpha)$ as follows

$$C_i = \begin{cases} Y_i - C_0(W_i; r_{\alpha,0}), & A_i = 1, D_i = 1 \\ C_1(W_i; r_{\alpha,1}) - Y_i, & A_i = 0, D_i = 1. \end{cases}$$

Next, we compute the non-conformity scores $R_{C,i}$ using the conformalized quantile residuals $R_{C,i} = \max\{\widehat{m}^L(W_i) - C_i^L, C_i^R - \widehat{m}^L(W_i)\}$, where (C_i^L, C_i^R) are the lower and upper

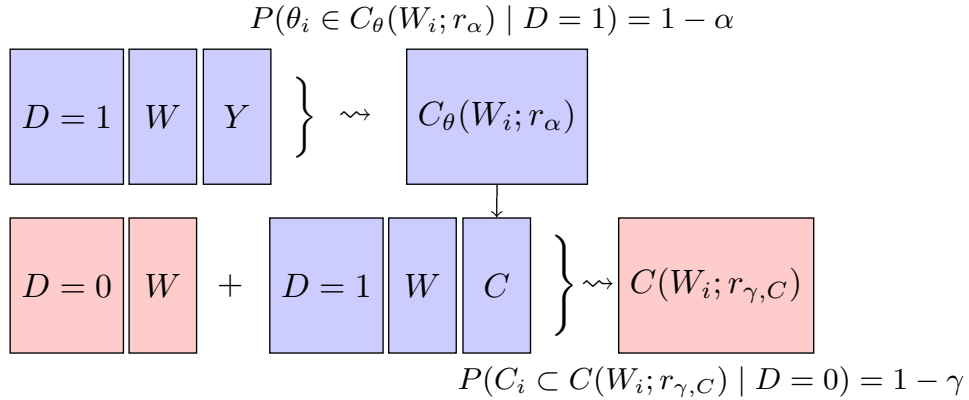

Figure 3: Schematic illustration for constructing the nested prediction intervals $C(W; r_{\alpha, C})$ for target data $D = 0$

endpoints of C_i , and $(\hat{m}^L(W_i), \hat{m}^R(W_i))$ are estimates of the conditional means of (C_i^L, C_i^R) given W_i .

Having obtained the non-conformity scores R_C for individuals in the source data, we aim to extend this information to the target data $D = 0$. Under Assumptions 4 and 5, we can relate the distribution of non-conformity scores in the target data to that in the source data through the following identification formula for the quantile $r_{\gamma, C}$:

$$1 - \gamma = P(R_C < r_{\gamma, C} \mid D = 0) = E_W \{P(R_C < r_{\gamma, C} \mid W, D = 1) \mid D = 0\},$$

where the desired coverage probability $1 - \gamma$ in the target data is ensured, adjusted for differences in the covariate distributions between the two datasets.

The identification formula serves as the foundation for estimating $r_{\gamma, C}$ and ensures that the constructed prediction intervals $C(W; r_{\gamma, C})$ achieve nominal coverage in the target data. Moreover, it motivates derivation of the EIF for $r_{\alpha, C}$, which we present in Theorem 4.

Theorem 4. *Under Assumptions 2-3, let $r_{\gamma, C}$ be the $(1 - \gamma)$ -th quantile of the non-conformity scores R_C . The EIF for $r_{\gamma, C}$ is, up to a proportionality constant, for Setting 2,*

$$\psi_C^{(S2)}(r_{\gamma, C}, W; m_C, \tilde{m}_C, e_D, \pi_A) = (1 - D)\{m_C(r_{\gamma, C}, X) - (1 - \gamma)\}$$

$$+ \{1 - e_D(X)\} \{\tilde{m}_C(r_{\gamma,C}, X, S) - m_C(r_{\gamma,C}, X)\} + D\pi_D(X) \{\mathbf{1}(R_C < r_{\gamma,C}) - \tilde{m}_C(r_{\gamma,C}, X, S)\},$$

and for Settings 1 and 3,

$$\begin{aligned} \psi_C^{(S1)}(r_{\gamma,C}, W; m_C, e_D, \pi_A) &= \psi_C^{(S3)}(r_{\gamma,C}, W; m_C, e_D, \pi_A) \\ &= (1 - D) \{m_C(r_{\gamma,C}, X) - (1 - \gamma)\} + D\pi_D(X) \{\mathbf{1}(R_C < r_{\gamma,C}) - m_C(r_{\gamma,C}, X)\}. \end{aligned}$$

Analogously, we could quantify the optimal efficiency gain from leveraging surrogates for estimating $r_{\gamma,C}$, which we formalize in Corollary 2.

Corollary 2. *Under Assumptions 2-3, the efficiency gain from using surrogates in estimating $r_{\gamma,C}$ in the target data is*

$$V_C^{(S1)} - V_C^{(S2)} = E [\pi_D(X) \{1 - e_D(X)\}^2 \text{var}\{\tilde{m}_C(r_{\gamma,C}, X, S) \mid X\}],$$

where $V_C^{(S1)} = \text{var}\{\psi_C^{(S1)}(r_{\gamma,C}, W; m_C, e_D, \pi_A)\}$, $V_C^{(S2)} = \text{var}\{\psi_C^{(S2)}(r_{\gamma,C}, W; m_C, \tilde{m}_C, e_D, \pi_A)\}$.

Corollary 2 shows that the efficiency gain from incorporating surrogates depends positively on the variance of $\tilde{m}_C(r_{\gamma,C}, X, S)$ given X . This variance captures the additional predictiveness of the surrogates for the non-conformity scores R_C given X .

To estimate $r_{\gamma,C}$ in practice, define $\hat{r}_{\gamma,C}^{(S1)}$ and $\hat{r}_{\gamma,C}^{(S2)}$ to be the smallest values satisfying

$$\sum_{i \in \mathcal{I}_2} \psi_C^{(S1)}(\hat{r}_{\gamma,C}^{(S1)}, W_i; \hat{m}_C, \hat{e}_D, \hat{\pi}_A) \geq 0, \quad \sum_{i \in \mathcal{I}_2} \psi_C^{(S2)}(\hat{r}_{\gamma,C}^{(S2)}, W_i; \hat{m}_C, \hat{\tilde{m}}_C, \hat{e}_D, \hat{\pi}_A) \geq 0,$$

where the nuisance functions are estimated on the first data fold \mathcal{I}_1 . Similar to Theorem 3, we can show that under both Setting 1 (or 3) and Setting 2, the coverage of the constructed prediction intervals satisfies

$$\begin{aligned} &P(\theta_i \notin C(W_i; \hat{r}_{\gamma,C}) \mid D_i = 0) \\ &\leq P(\theta_i \notin C_i \mid D_i = 0) + P(C_i \not\subset C(W_i; \hat{r}_{\gamma,C}) \mid D_i = 0) \leq \alpha + \gamma + o_p(1), \end{aligned}$$

demonstrating that the probability of the true causal parameter θ_i not being contained in the final prediction interval $C(W_i; \hat{r}_{\gamma,C})$ is bounded above by $\alpha + \gamma$ up to a negligible term.

The nested prediction intervals are designed to adapt jointly to the uncertainty of the lower and upper endpoints of C_i , ensuring that the overall coverage is at least $1 - (\alpha + \gamma)$. Thus, we can show that under both Setting 1 (or 3) and Setting 2,

$$P(\theta_i \in C_\theta(W_i; \widehat{r}_{\gamma,C}) \mid D_i = 0) \geq 1 - (\alpha + \gamma),$$

holds asymptotically, which guarantees the asymptotic coverage.

6 Simulation studies

In this section, we demonstrate the performance of SCIENCE and showcase its efficiency gain under various settings via simulation studies. We begin by considering a data-generation procedure similar to that in Kallus and Mao (2020).

Specifically, we first generate baseline covariate $X \in \mathbb{R}^2$ following a multivariate normal distribution $X \sim N(0, I_2)$ for the entire population, with total sample sizes $N = 3000, 5000, 10000$. Next, we randomly select a diminishing proportion $P(D = 1) = N^{-1/4}$ of the entire population as the source data ($D = 1$), while the remaining data constitute the target data ($D = 0$). The treatment variable is generated according to a logistic regression model: $P(A = 1 \mid X) = 1/\{1 + \exp(-\alpha_A - \sum_j \eta_j X_j)\}$, where $\eta_1 = \eta_2 = -1/2$ and α_A is adaptively chosen to ensure an average treatment rate of 0.5. We then simulate potential surrogate outcomes $S(a) \in \mathbb{R}^2$ by $S(a) \sim N((-1)^{a+1}, \sigma_S^2 I_2)$, where $\sigma_S = 1, 5, 10, 50$. Finally, we generate potential primary outcomes $Y(a)$ by:

$$Y(a) = (-1)^{a+1} + \frac{(-1)^a}{2} \frac{\sum_{j=1}^2 S_j(a)}{5} + \sum_{j=1}^2 \beta_j X_j + \epsilon, \quad \epsilon \sim N(0, 1),$$

where $\beta_1 = \beta_2 = 1$. One can observe that the increase in the explained variance of $Y(a)$ by the surrogates $S(a)$, adjusting for the baseline covariates, is $\sigma_S^2/100$. Thus, the variance σ_S^2 quantifies how predictive the surrogates are for the primary potential outcomes $Y(a)$, after accounting for the baseline covariates. Moreover, the surrogates can be considered as important as the covariates when $\sigma_S = 10$, which we treat as the benchmark scenario for the subsequent model evaluation.

We are interested in evaluating the properties of the prediction intervals for the ITEs over the combined data, as well as separately for the target and source data. In our analysis, X , A , $S(A)$, and $Y(A)$ are observed for the source data, while only X , A , and $S(A)$ are observed for the target data. Therefore, we can calculate the proposed semi-parametric efficient estimators both with and without access to the surrogates in the target data. The non-conformity scores R_a and R_C are constructed using conformalized quantile residuals from the quantile regression model available in the `quantreg` package, which fits the 2.5% and 97.5% conditional quantiles of $Y(a)$. The propensity scores and other nuisance functions required for finding the efficient estimators are fitted using `SuperLearner`, with Random Forest and generalized linear models as base learners. We split 75% of the data as the first fold \mathcal{I}_1 for model training, as suggested by Sesia and Candès (2020), and use the remaining data to construct the prediction intervals. Furthermore, we compare the proposed methods against the weighted CQR (WCQR) proposed in Lei and Candès (2021).

Figure 4(A) presents the empirical coverage and average width of the prediction intervals for the ITE across 500 Monte Carlo simulations. While all methods are guaranteed to cover the ITE, we note that nested conformal inference for the target data tends to be overly conservative when primary outcomes are missing, a phenomenon also observed in Lei and Candès (2021). As expected, both semi-parametric efficient estimators produce shorter intervals than the WCQR, while still maintaining valid coverage. Among all methods, SCIENCE achieves the shortest intervals. The efficiency gains from using surrogates are further illustrated in Figure 4(B) for $\sigma_S = 1, 5, 10, 30$. The benefits are measured by the average relative width of the prediction intervals compared to those obtained without using surrogates. As demonstrated by Corollaries 1 and 2, the improvement from using surrogates is more pronounced as σ_S increases. This is because, with higher σ_S , surrogates account for more variation of the primary outcomes, leading to better predictiveness when constructing prediction intervals for the ITE.

6.1 Group-conditional performance for continuous outcomes

In this section, we evaluate the group-conditional performance of the SCIENCE framework for continuous outcomes; more simulation studies of group-conditional performance

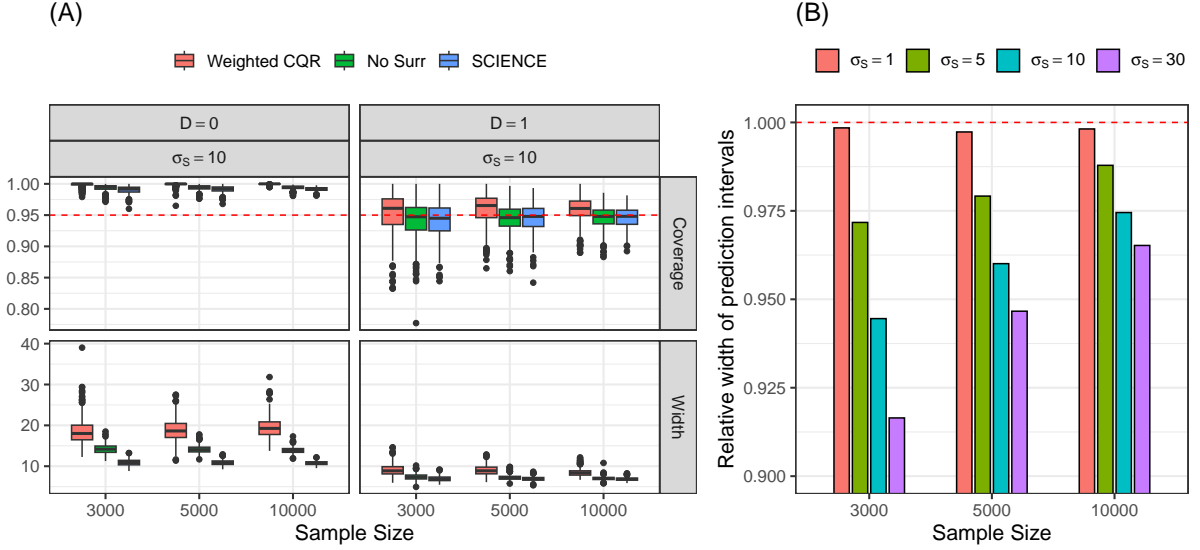

Figure 4: (A) Empirical coverage and width of the 95% prediction intervals, when $\sigma_S = 10$ and (B) average relative width of the 95% prediction intervals (‘SCIENCE’ versus ‘No Surr’) when $\sigma_S = 1, 5, 10, 30$ for ITE across 500 replicates.

for categorical outcomes are provided in Section B of the Supplementary Material. We follow data-generation procedures similar to those in the previous section, except that we additionally generate the group variable G with three levels from a multinomial distribution. Specifically, $P(G = 1 | X) \propto \exp(-\alpha_{G,1} - \sum_j X_j/2)$, $P(G = 2 | X) \propto \exp(-\alpha_{G,2} - X_1 - X_2/2)$, and $P(G = 3 | X) \propto \exp(-\alpha_{G,3} - X_1/2 - X_2)$, where $\alpha_R = (\alpha_{G,1}, \alpha_{G,2}, \alpha_{G,3})$ is adaptively chosen to ensure the proportion of each group is around 0.5, 0.3, and 0.2, respectively. The generation of the treatment variable A and the potential primary outcomes $Y(a)$ are modified to include the effect of group variable: $P(A = 1 | X, G) = 1/\{1 + \exp(-\alpha_A - \sum_j \eta_j X_j + G)\}$, and

$$Y(a) = (-1)^{a+1} + \frac{(-1)^a \sum_{j=1}^2 S_j(a)}{5} + \sum_{j=1}^2 \beta_j X_j + G + \epsilon, \quad \epsilon \sim N(0, 1).$$

Figure 5 presents the empirical coverage and average width of the prediction intervals for the ITE of the combined data when $\sigma_S = 10$, conditional on the group variables G . All methods achieve valid 95% conditional coverage within each group and SCIENCE produces the shortest intervals – on average, 48% and 22% shorter than the WCQR and efficient estimator without surrogates, respectively.

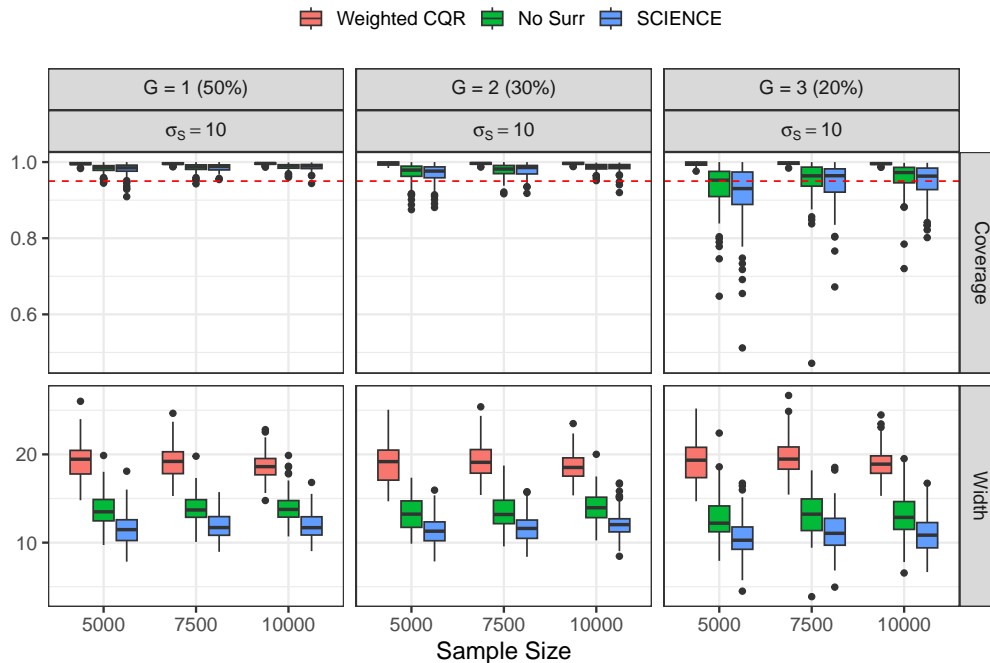

Figure 5: Empirical coverage and width of the 95% prediction intervals for the ITE of the combined data when $\sigma_S = 10$, conditional on the group variable G , across 500 replicates.

7 Real data analysis

We analyzed the Moderna COVE phase 3 COVID-19 vaccine efficacy trial that randomized adults to receive two doses of mRNA-1273 vaccination or placebo at Day 1 and Day 29, conducting a per-protocol analysis that included participants who received both injections without specified protocol violations. Analyses have been completed and will be included pending final review and approval from Moderna.

8 Discussion

In this paper, we proposed a novel surrogate-assisted conformal inference framework (SCIENCE) for constructing more efficient individualized prediction intervals. Our method is broadly applicable, accommodating scenarios where primary outcomes may or may not be observed. By leveraging semiparametric efficient estimation, SCIENCE is capable of handling distributional shifts between source and target populations, achieving the desired PAC (probably approximately correct) asymptotic coverage property, where coverage bias

is a product of estimation errors. Consequently, SCIENCE ensures nominal coverage rates, provided that flexible non-parametric models used for nuisance function estimation meet the required rate of convergence conditions.

While our approach achieves group-conditional coverage over pre-specified subgroups, future research could extend these guarantees to more comprehensive and formally developed notions of fairness. Moreover, prediction intervals are not the only form of uncertainty quantification. An intriguing avenue for future work would be the exploration of conformal predictive distributions, which output a probability distribution over the response space rather than a fixed prediction interval, allowing for potentially more informative uncertainty quantification (Vovk et al., 2017). Another area of interest is class-conditional coverage, where coverage is guaranteed for specific outcome classes (Ding et al., 2024). This extension could enhance the applicability of our method in settings where outcome-dependent coverage is crucial for decision-making, thereby improving the interpretability and reliability of individualized prediction intervals across different outcome groups. Finally, post-selection inference remains an essential consideration for practical applications. Iteratively choosing and refining the miscoverage rate α can be valuable when an initially aggressive choice (i.e., small α) results in prediction intervals that are too wide to be useful. Investigating adaptive strategies for re-selecting α to balance interval width and coverage validity could improve the adoption of conformal inference methods for precision medicine and beyond.

Supplementary Materials

The Supplementary Materials include the following information: Section A provides the proofs of Theorems 2 to 4, as well as of Corollaries 1 and 2. We provide additional simulation results in Section B, and additional results for real-data analysis in Section C.

A Technical Proofs and Details

A.1 Proof of Theorem 2

Let t denote the index for the parametric submodels $f_t(\mathcal{O})$ of the observed data with true density function evaluated at $t = t^*$, i.e., $f(\mathcal{O}) = f_{t^*}(\mathcal{O})$, where

$$f(\mathcal{O}) = f(X) \times e_A(X)^A \{1 - e_A(X)\}^{1-A} \times e_D(X, A)^D \{1 - e_D(X, A)\}^{1-D} \\ \times f(S | D, A, X) \times f(Y | S, D, A, X),$$

the observed score function is derived by the pathwise derivatives of $\log f_t(\mathcal{O})$ with respect to t , given by $s_t(\mathcal{O}) = s_t(Y | S, D, A, X) + s_t(S | D, A, X) + s_t(D | A, X) + s_t(A | X) + s_t(X)$. The tangent space corresponding to this model is $\Lambda = \Lambda_X \oplus \Lambda_{A|X} \oplus \Lambda_{D|A,X} \oplus \Lambda_{S|D,A,X} \oplus \Lambda_{Y|S,D,A,X}$, where Λ_X , $\Lambda_{A|X}$, $\Lambda_{D|A,X}$, $\Lambda_{S|D,A,X}$, and $\Lambda_{Y|S,D,A,X}$ are the mean square closures of the score vector of the submodels:

$$\Lambda_X = \{\Gamma(X) : \int \Gamma(x) f(x) dx = 0\}, \\ \Lambda_{A|X} = \{\{A - e_A(X)\} a(X)\}, \quad \Lambda_{D|A,X} = \{A \{D - e_D(X, A)\} b(X)\}, \\ \Lambda_{S|D,A,X} = \{\Gamma(S, D, A, X) : \int \Gamma(s, D, A, X) f(S | D, A, X) ds = 0\}, \\ \Lambda_{Y|S,D,A,X} = \{\Gamma(Y, S, D, A, X) : \int \Gamma(y, S, D, A, X) f(y | S, D, A, X) dy = 0\},$$

for any two arbitrary square-integrable measurable functions $a(X)$ and $b(X)$.

Let $u(R_1, r_{\alpha,1}) = \mathbf{1}(R_1 \leq r_{\alpha,1} | A = 0, D = 1) - (1 - \alpha)$, and $r_1(t)$ be the corresponding $(1 - \alpha)$ -quantile for $R_1 | A = 0, D = 1$ under the parametric submodels, which satisfies

$E_t[u\{R_1, r_1(t)\}] = 0$ with $r(t^*) = r_{\alpha,1}$. Next, we can show that

$$0 = \frac{\partial}{\partial t} E_t[u\{R_1, r_1(t)\}]|_{t=t^*} = \frac{\partial}{\partial t} E_t[u\{R_1, r_1(t^*)\}]|_{t=t^*} + \frac{\partial}{\partial r_1} E_{t^*}[u\{R_1, r_1(t^*)\}] \frac{\partial r_1(t)}{\partial t} |_{t=t^*},$$

which leads to

$$\frac{\partial r_1(t)}{\partial t} |_{t=t^*} = \left[-\frac{\partial}{\partial r_1} E_{t^*}\{u(R_1, r_{\alpha,1})\} \right]^{-1} \frac{\partial}{\partial t} E_t\{u(R_1, r_{\alpha,1})\} |_{t=t^*} \propto \frac{\partial}{\partial t} E_t\{u(R_1, r_{\alpha,1})\} |_{t=t^*}.$$

Under Assumptions 2 to 3, we have

$$\begin{aligned} \frac{\partial}{\partial t} E_t\{u(R_1, r_{\alpha,1})\} |_{t=t^*} &= \frac{\partial}{\partial t} P_t(R_1 < r_{\alpha,1} | A = 0, D = 1) |_{t=t^*} \\ &\propto \frac{\partial}{\partial t} E_{X,t}[E_{S,t}\{P_{Y,t}(R_1 < r_{\alpha,1} | A = 1, D = 1, S, X) | A = 1, X\} | A = 0, D = 1] |_{t=t^*} \\ &\propto \frac{\partial}{\partial t} E_{X,t}[(1 - A)DE_{S,t}\{P_{Y,t}(R_1 < r_{\alpha,1} | A = 1, D = 1, S, X) | A = 1, X\}] |_{t=t^*} \\ &\propto \frac{\partial}{\partial t} E_{X,t}[P_t(A = 0, D = 1 | X)E_{S,t}\{P_{Y,t}(R_1 < r_{\alpha,1} | A = 1, D = 1, S, X) | A = 1, X\}] |_{t=t^*} \\ &= T_1 + T_2 + T_3 + T_4, \end{aligned}$$

which is constituted by five terms $T_1, T_2, T_3,$ and T_4 . We analyze these four terms separately,

$$\begin{aligned} T_1 &= \frac{\partial}{\partial t} E_{X,t}\{P(A = 0, D = 1 | X)m_1(r, X)\} |_{t=t^*} \\ &= E_X[P(A = 0, D = 1 | X)\{m_1(r, X) - (1 - \alpha)\}s(X)], \\ T_2 &= \frac{\partial}{\partial t} E_X\{P_t(A = 0, D = 1 | X)m_1(r, X)\} |_{t=t^*} \\ &= E\{[(1 - A)D - \{1 - e_A(X)\}e_D(X, 0)]m_1(r, X)s(D, A | X)\}, \\ T_3 &= \frac{\partial}{\partial t} E_X[P(A = 0, D = 1 | X)E_{S,t}\{\tilde{m}_1(r, X, S) | A = 1, X\}] |_{t=t^*} \\ &= E \left[P(A = 0, D = 1 | X) \frac{A}{e_A(X)} \{\tilde{m}_1(r, X, S) - m_1(r, X)\} s(S | D, A, X) \right], \end{aligned}$$

and

$$\begin{aligned} T_4 &= \frac{\partial}{\partial t} E_X[P(A = 0, D = 1 | X)E_S\{P_{Y,t}(R_1 < r_{\alpha,1} | A = 1, D = 1, S, X) | A = 1, X\}] |_{t=t^*} \\ &= \frac{\partial}{\partial t} E_X \left(P(A = 0, D = 1 | X) E \left[\frac{D \{\mathbf{1}(R_1 \leq r_{\alpha,1}) - \tilde{m}_1(r, X, S)\}}{e_D(X, 1)} s(Y | S, D, A, X) | A = 1, X \right] \right) \end{aligned}$$

$$= \frac{\partial}{\partial t} E \left[P(A = 0, D = 1 | X) \frac{AD \{\mathbf{1}(R_1 \leq r_{\alpha,1}) - \tilde{m}_1(r, X, S)\}}{e_A(X)e_D(X, 1)} s(Y | S, D, A, X) \right].$$

Putting these terms together, we can show that

$$\frac{\partial r(t)}{\partial t} \Big|_{t=t^*} \propto \frac{\partial}{\partial t} E_t \{u(R_1, r_{\alpha,1})\} \Big|_{t=t^*} = E \{\psi_1(r_{\alpha,1}, W; m, \tilde{m}, e_D, \pi_A) s(Y, S, D, A, X)\},$$

and

$$\begin{aligned} \psi_1(r_{\alpha,1}, W; m, \tilde{m}, e_D, \pi_A) &= D(1 - A) \{m_1(r_{\alpha,1}, X) - (1 - \alpha)\} \\ &+ A\pi_A(X)e_D(X, 0) \{\tilde{m}_1(r_{\alpha,1}, X, S) - m_1(r_{\alpha,1}, X)\} \\ &+ \frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)} \{\mathbf{1}(R_1 < r_{\alpha,1}) - \tilde{m}_1(r_{\alpha,1}, X, S)\}, \end{aligned}$$

where

$$\begin{aligned} D(1 - A) \{m_1(r_{\alpha,1}, X) - (1 - \alpha)\} &\in \Lambda_X \\ A\pi_A(X)e_D(X, 0) \{\tilde{m}_1(r_{\alpha,1}, X, S) - m_1(r_{\alpha,1}, X)\} &\in \Lambda_{S|D,A,X} \\ \frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)} \{\mathbf{1}(R_1 < r_{\alpha,1}) - \tilde{m}_1(r_{\alpha,1}, X, S)\} &\in \Lambda_{Y|S,D,A,X}. \end{aligned}$$

Thus, it completes the proof of Theorem 2 by the definition of efficient influence function.

A.2 Proof of Theorem 3

Under Lemma 2, we can show that for the empirically estimated \hat{r}_α using the second data fold \mathcal{I}_2 under Setting 2,

$$\begin{aligned} \mathbb{P}(R_1 \leq \hat{r}_{\alpha,1}^{(S2)} | A = 0, D = 1) - (1 - \alpha) &= \frac{\mathbb{P}_{\mathcal{I}_2} \{\hat{\psi}_1^{(S2)}(r_{\alpha,1}, W)\}}{P(A = 0, D = 1)} \\ &+ \frac{\mathbb{P}\{\hat{\psi}_1^{(S2)}(r_{\alpha,1}, W)\} - \mathbb{P}_{\mathcal{I}_2} \{\hat{\psi}_1^{(S2)}(r_{\alpha,1}, W)\}}{P(A = 0, D = 1)} + \frac{\mathbb{P}\{\hat{\psi}_1^{(S2)}(r_{\alpha,1}, W) - \psi_1^{(S2)}(r_{\alpha,1}, W)\}}{P(A = 0, D = 1)} \\ &\geq 0 + I_1 + I_2. \end{aligned}$$

Here, we use the fact that $\mathbb{P}_{\mathcal{I}_2}\{\widehat{\psi}_1^{(S2)}(r_{\alpha,1}, W)\} \geq 0$ by definition. The term I_1 is negligible if $\psi_1^{(S2)}(r_{\alpha,1}, W)$ belongs to a Donsker class (Van der Vaart, 2000). Even if the Donsker condition is not met, the sample-splitting procedure in Chernozhukov et al. (2018) can be used to assure that I_1 is negligible, where the first data fold \mathcal{I}_1 is used to estimate $\widehat{\pi}_A$, \widehat{e}_D , \widehat{m}_a and \widehat{m} , and the second data fold \mathcal{I}_2 is used to compute $r_{\alpha,1}$; see Lemma A.1 for more details on the bound of I_1 .

The term I_2 is the second-order remainder term, which is bounded by the product of estimation error for the nuisance functions:

$$\begin{aligned}
& \mathbb{P}\{\widehat{\psi}_1^{(S2)}(r, W) - \psi_1^{(S2)}(r, W)\} = \mathbb{P}[P(A = 0 | X)e_D(X, 0)\{\widehat{m}_1(r, X) - m_1(r, X)\}] \\
& + \mathbb{P}\left[P(A = 1 | X)\widehat{\pi}_A(X)\widehat{e}_D(X, 0)\{\widehat{m}_1(r, X, S) - \widehat{m}_1(r, X)\}\right] \\
& + \mathbb{P}\left[P(A = 1 | X)\widehat{\pi}_A(X)\frac{e_D(X, 1)}{\widehat{e}_D(X, 1)}\widehat{e}_D(X, 0)\{\widehat{m}_1(r, X, S) - \widehat{m}_1(r, X, S)\}\right] \\
& = \mathbb{P}[P(A = 0 | X)e_D(X, 0)\{\widehat{m}_1(r, X) - m_1(r_{\alpha,1}, X)\}] \\
& + \mathbb{P}\left[P(A = 1 | X)\widehat{\pi}_A(X)\widehat{e}_D(X, 0)\{\widehat{m}_1(r, X, S) - \widetilde{m}_1(r, X, S) + m_1(r, X) - \widehat{m}_1(r, X)\}\right] \\
& + \mathbb{P}\left[P(A = 1 | X)\widehat{\pi}_A(X)\frac{e_D(X, 1)}{\widehat{e}_D(X, 1)}\widehat{e}_D(X, 0)\{\widehat{m}_1(r, X, S) - \widetilde{m}_1(r, X, S)\}\right] \\
& = \mathbb{P}\left[P(A = 0 | X)\left\{\frac{\pi_A(X)e_D(X, 0) - \widehat{\pi}_A(X)\widehat{e}_D(X, 0)}{\pi_A(X)}\right\}\{\widehat{m}_1(r, X) - m_1(r, X)\}\right] \\
& + \mathbb{P}\left[P(A = 1 | X)\widehat{\pi}_A(X)\widehat{e}_D(X, 0)\left\{\frac{\widehat{e}_D(X, 1) - e_D(X, 1)}{\widehat{e}_D(X, 1)}\right\}\{\widehat{m}_1(r, X, S) - \widetilde{m}_1(r, X, S)\}\right] \\
& \lesssim \|\widehat{\pi}_A(X) - \pi_A(X)\| \cdot \sup_r \|\widehat{m}_1(r, X) - m_1(r, X)\| \\
& + \|\widehat{e}_D(X, 0) - e_D(X, 0)\| \cdot \sup_r \|\widehat{m}_1(r, X) - m_1(r, X)\| \\
& + \|\widehat{e}_D(X, 1) - e_D(X, 1)\| \cdot \sup_r \|\widehat{m}_1(r, X, S) - \widetilde{m}_1(r, X, S)\|,
\end{aligned}$$

where the last inequality follows from the Cauchy–Schwarz inequality. Combining the bounds for I_1 and I_2 gives us

$$\begin{aligned}
& P(R_a \leq \widehat{r}_{\alpha,a}^{(S2)} | A_i = 1 - a, D_i = 1) \geq (1 - \alpha) \\
& - C_0 \frac{\pi_0 \bar{e}_0 (\underline{e}_0^{-1} + m_0 + \underline{e}_0^{-1} \widetilde{m}_0)}{P(A = 1 - a, D = 1)} \sqrt{\frac{\log(1/\delta) + 1}{|\mathcal{I}_2|}}
\end{aligned}$$

$$\begin{aligned}
& - C_1 \left\{ \frac{\|\widehat{\pi}_A(X) - \pi_A(X)\|}{P(A = 1 - a, D = 1)} \cdot \sup_r \|\widehat{m}_a(r, X) - m_a(r, X)\| \right. \\
& + \frac{\|\widehat{e}_D(X, A) - e_D(X, A)\|}{P(A = 1 - a, D = 1)} \cdot \sup_r \|\widehat{m}_a(r, X) - m_a(r, X)\| \\
& \left. + \frac{\|\widehat{e}_D(X, A) - e_D(X, A)\|}{P(A = 1 - a, D = 1)} \cdot \sup_r \|\widehat{\tilde{m}}_a(r, X, S) - \tilde{m}_a(r, X, S)\| \right\},
\end{aligned}$$

and the proof for $P(R_\alpha \leq \widehat{r}_{\alpha, a}^{(S1)} \mid A_i = 1 - a, D_i = 1)$ under Settings 1 or 3 can be completed in a similar manner.

A.3 Proof of Corollary 1

By straightforward algebra, the semi-parametric lower bound for estimating $r_{\alpha, 1}$ without surrogates for $\psi_1^{(S1)}(r_{\alpha, 1}, W; m, \tilde{m}, e_D, \pi_A)$ in Theorem 2 is

$$V^{(S1)} = \text{var}\{\psi_1^{(S1)}(r_{\alpha, 1}, W; m, \tilde{m}, e_D, \pi_A)\} = V_1 + V_2 + V_3 + 2V_{12} - 2V_{13} - 2V_{23},$$

where

$$\begin{aligned}
V_1 &= \text{var}[D(1 - A)\{m_1(r_{\alpha, 1}, X) - (1 - \alpha)\}], \\
V_2 &= \text{var}\left\{\frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}\mathbf{1}(R_1 < r_{\alpha, 1})\right\}, \\
V_3 &= \text{var}\left\{\frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}m_1(r_{\alpha, 1}, X)\right\}, \\
V_{12} &= V_{13} \\
&= \text{cov}\left[D(1 - A)\{m_1(r_{\alpha, 1}, X) - (1 - \alpha)\}, \frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}m_1(r_{\alpha, 1}, X)\right], \\
V_{23} &= V_3 \\
&= \text{cov}\left[\frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}\mathbf{1}(R_1 < r_{\alpha, 1}), \frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}m_1(r_{\alpha, 1}, X)\right], \\
&= \text{var}\left\{\frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}m_1(r_{\alpha, 1}, X)\right\}.
\end{aligned}$$

In addition, we can show that the efficiency lower bound with surrogates is

$$V^{(S2)} = \text{var}\{\psi_1^{(S2)}(W; m, \tilde{m}, e_D, \pi_A)\}$$

$$= \tilde{V}_1 + \tilde{V}_2 + \tilde{V}_3 + \tilde{V}_4 + 2\tilde{V}_{12} + 2\tilde{V}_{13} - 2\tilde{V}_{14} + 2\tilde{V}_{23} - 2\tilde{V}_{24} - 2\tilde{V}_{34},$$

where

$$\tilde{V}_1 = \text{var}[D(1 - A)\{m_1(r_{\alpha,1}, X) - (1 - \alpha)\}]$$

$$\tilde{V}_2 = \text{var}[A\pi_A(X)e_D(X, 0)\{\tilde{m}_1(r_{\alpha,1}, X, S) - m_1(r_{\alpha,1}, X)\}],$$

$$\tilde{V}_3 = \text{var}\left\{\frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}\mathbf{1}(R_1 < r_{\alpha,1})\right\},$$

$$\tilde{V}_4 = \text{var}\left\{\frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}\tilde{m}_1(r_{\alpha,1}, X, S)\right\},$$

$$\tilde{V}_{12} = \text{cov}[D(1 - A)\{m_1(r_{\alpha,1}, X) - (1 - \alpha)\}, A\pi_A(X)e_D(X, 0)\{\tilde{m}_1(r_{\alpha,1}, X, S) - m_1(r_{\alpha,1}, X)\}] = 0,$$

$$\tilde{V}_{13} = \tilde{V}_{14}, \quad \tilde{V}_{23} = \tilde{V}_{24}, \quad \tilde{V}_{34} = \tilde{V}_4.$$

Hence, we can verify that under Assumptions 5 and 3,

$$\begin{aligned} V^{(S1)} - V^{(S2)} &= \tilde{V}_4 - \tilde{V}_3 - \tilde{V}_2 \\ &= \text{var}\left\{\frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}\tilde{m}_1(r_{\alpha,1}, X, S)\right\} - \text{var}\left\{\frac{AD\pi_A(X)e_D(X, 0)}{e_D(X, 1)}m_1(r_{\alpha,1}, X)\right\} \\ &\quad - \text{var}[A\pi_A(X)e_D(X, 0)\{\tilde{m}_1(r_{\alpha,1}, X, S) - m_1(r_{\alpha,1}, X)\}] \\ &= E\left[\frac{P(A = 1, D = 1 | X)\pi_A^2(X)e_D^2(X, 0)}{e_D^2(X, 1)}\text{var}\{\tilde{m}_1(r_{\alpha,1}, X, S) | X, A = 1, D = 1\}\right] \\ &\quad - E[e_A(X)\pi_A^2(X)e_D^2(X, 0)\text{var}\{\tilde{m}_1(r_{\alpha,1}, X, S) | X, A = 1\}] \\ &= E\left[\frac{1 - e_D(X, 1)}{e_D(X, 1)}\frac{e_D^2(X, 0)\{1 - e_A(X)\}^2}{e_A(X)}\text{var}\{\tilde{m}_1(r_{\alpha,1}, X, S) | X\}\right], \end{aligned}$$

since $\tilde{V}_1 = V_1$ and $\tilde{V}_3 = V_2$, which completes the proof of Corollary 1.

A.4 Proof of Theorem 4

Under Assumptions 2 to 3, the $(1 - \alpha)$ -th quantile $r_{\gamma, C}$ of $R_C | D = 0$ can be identified by

$$\begin{aligned} P\{Y(1) - Y(0) \in C | D = 0\} &= E[P\{Y(1) - Y(0) \in C | X, D = 0\} | D = 0] \\ &= E[P\{Y(1) - Y(0) \in C | X, D = 1\} | D = 0] \end{aligned}$$

$$\begin{aligned}
&= E[P\{R_C < r_{\gamma,C} \mid X, D = 1\} \mid D = 0] \\
&= \frac{1}{P(D = 0)} E[(1 - D)P\{R_C < r_{\gamma,C} \mid X, D = 1\}] \\
&= \frac{1}{P(D = 0)} E[P(D = 0 \mid X)P\{R_C < r_{\gamma,C} \mid X, D = 1\}] \\
&= \frac{1}{P(D = 0)} E(P(D = 0 \mid X)E[P\{R_C < r_{\gamma,C} \mid X, S, D = 1\} \mid X]),
\end{aligned}$$

where the last equation holds as $D \perp \{Y(a), S(a)\} \mid X$ by Assumption 5. Next, we can derive the EIF for $r_{\gamma,C}$, similar to the proof of Theorem 2:

$$\begin{aligned}
\psi_C(W; m_C, \tilde{m}_C, e_D, \pi_A) &= \{1 - e_D(X)\}m_C(r_{\gamma,C}, X) + \{1 - D - 1 + e_D(X)\}m_C(r_{\gamma,C}, X) \\
&+ \{1 - e_D(X)\}\{\tilde{m}_C(r_{\gamma,C}, X, S) - m_C(r_{\gamma,C}, X)\} \\
&+ \{1 - e_D(X)\}\frac{D}{e_D(X)}\{\mathbf{1}(R_C < r_{\gamma,C}) - \tilde{m}_C(r_{\gamma,C}, X, S)\} \\
&= (1 - D)m_C(r_{\gamma,C}, X) \\
&+ \{1 - e_D(X)\}\{\tilde{m}_C(r_{\gamma,C}, X, S) - m_C(r_{\gamma,C}, X)\} + De_D(X)\{\mathbf{1}(R_C < r_{\gamma,C}) - \tilde{m}_C(r_{\gamma,C}, X, S)\},
\end{aligned}$$

where $\tilde{m}_C(r_{\gamma,C}, X, S) = P(R_C < r_{\gamma,C} \mid X, S, D = 1)$, $m_C(r_{\gamma,C}, X) = E\{\tilde{m}_C(r_{\gamma,C}, X, S) \mid X\}$, and $e_D(X) = \{1 - e_D(X)\}/e_D(X)$.

A.5 Proof of Corollary 2

The semi-parametric efficiency lower bound for estimating $r_{\gamma,C}$ without surrogates is

$$\begin{aligned}
V_C^{(S1)} &= \text{var}\{\psi_C^{(S1)}(r_{\gamma,C}, W; m_C, e_D, \pi_A)\} \\
&= V_1^C + V_2^C + V_3^C + 2V_{12}^C - 2V_{13}^C - 2V_{23}^C,
\end{aligned}$$

where

$$\begin{aligned}
V_1^C &= \text{var}[(1 - D)\{m_C(r_{\gamma,C}, X) - (1 - \gamma)\}], \\
V_2^C &= \text{var}[D\pi_D(X)\mathbf{1}(R_C < r_{\gamma,C})], \quad V_3^C = \text{var}\{D\pi_D(X)m_C(r_{\gamma,C}, X)\}, \\
V_{12}^C &= V_{13}^C = 0,
\end{aligned}$$

$$V_{23}^C = \text{cov} [D\pi_D(X)\mathbf{1}(R_C < r_{\gamma,C}), D\pi_D(X)m_C(r_{\gamma,C}, X)] = V_3^C.$$

Similarly, we can show that the efficiency lower bound with surrogates is

$$\begin{aligned} \tilde{V}_C^{(S2)} &= \text{var} \{ \psi_C^{(S2)}(r_{\gamma,C}, W; m_C, \tilde{m}_C, e_D, \pi_A) \} \\ &= \tilde{V}_1^C + \tilde{V}_2^C + \tilde{V}_3^C + \tilde{V}_4^C \\ &\quad + 2\tilde{V}_{12}^C + 2\tilde{V}_{13}^C - 2\tilde{V}_{14}^C + 2\tilde{V}_{23}^C - 2\tilde{V}_{24}^C - 2\tilde{V}_{34}^C \end{aligned}$$

where

$$\begin{aligned} \tilde{V}_1^C &= \text{var} [(1 - D)\{m_C(r_{\gamma,C}, X) - (1 - \gamma)\}], \\ \tilde{V}_2^C &= \text{var} [\{1 - e_D(X)\}\{\tilde{m}_C(r_{\gamma,C}, X, S) - m_C(r_{\gamma,C}, X)\}] \\ \tilde{V}_3^C &= \text{var} \{D\pi_D(X)\mathbf{1}(R_C < r_{\gamma,C})\}, \quad \tilde{V}_4^C = \text{var} \{D\pi_D(X)\tilde{m}_C(r_{\gamma,C}, X, S)\}, \\ \tilde{V}_{12}^C &= \tilde{V}_{13}^C = \tilde{V}_{14}^C = 0, \\ \tilde{V}_{23}^C &= \tilde{V}_{24}^C \\ &= \text{cov} [\{1 - e_D(X)\}\{\tilde{m}_C(r_{\gamma,C}, X, S) - m_C(X)\}, D\pi_D(X)\tilde{m}_C(r_{\gamma,C}, X, S)], \\ \tilde{V}_{34}^C &= \text{cov} [D\pi_D(X)\mathbf{1}(R_C < r_{\gamma,C}), D\pi_D(X)\tilde{m}_C(r_{\gamma,C}, X, S)] = \tilde{V}_4^C. \end{aligned}$$

Therefore, we can verify that

$$\begin{aligned} V_C^{(S1)} - V_C^{(S2)} &= \tilde{V}_4^C - V_3^C - \tilde{V}_2^C \\ &= \text{var} \{D\pi_D(X)\tilde{m}_C(r_{\gamma,C}, X, S)\} - \text{var} \{D\pi_D(X)m_C(r_{\gamma,C}, X)\} \\ &\quad - \text{var} [\{1 - e_D(X)\}\{\tilde{m}_C(r_{\gamma,C}, X, S) - m_C(r_{\gamma,C}, X)\}] \\ &= E \{D\pi_D^2(X)\tilde{m}_C^2(r_{\gamma,C}, X, S)\} - E \{D\pi_D^2(X)m_C^2(r_{\gamma,C}, X)\} \\ &\quad - E [\{1 - e_D(X)\}^2\{\tilde{m}_C(r_{\gamma,C}, X, S) - m_C(r_{\gamma,C}, X)\}^2] \\ &= E \left[\frac{\{1 - e_D(X)\}^2}{e_D(X)} \{\tilde{m}_C^2(r_{\gamma,C}, X, S) - m_C^2(r_{\gamma,C}, X)\} \right] \\ &\quad - E [\{1 - e_D(X)\}^2\{\tilde{m}_C^2(r_{\gamma,C}, X, S) - m_C^2(r_{\gamma,C}, X)\}] \\ &= E [\pi_D(X)\{1 - e_D(X)\}^2 \text{var} \{\tilde{m}_C(r_{\gamma,C}, X, S) | X\}], \end{aligned}$$

where $V_1^C = \tilde{V}_1^C$ and $V_2^C = \tilde{V}_3^C$. Hence, it completes the proof of Corollary 2.

A.6 Additional technical details

A.6.1 Proof of Lemma 1

The proof of Lemma 2.2 in Kallus and Mao (2020) shows that $D \perp \{Y(a), S(a)\} \mid X, A$ under Assumptions 4 and 5. Under Assumption 3, we have $(A, D) \perp \{Y(a), S(a)\} \mid X$, which proves Condition (a), that is, $D \perp \{Y(a), S(a)\} \mid X$, and Conditions (b) and (c) $A \perp \{Y(a), S(a)\} \mid X, D$ by Theorem 17.2 in Wasserman (2013).

A.6.2 Proof of Lemma 2

On the one hand, we can show that

$$\begin{aligned}
P(R_1 \leq r_{\alpha,1} \mid A = 0, D = 1) &= E\{E(R_1 \leq r_{\alpha,1} \mid X, A = 0, D = 1) \mid A = 0, D = 1\} \\
&= E\{E(R_1 \leq r_{\alpha,1} \mid X, A = 1, D = 1) \mid A = 0, D = 1\} \text{ (Assumption 3)} \\
&= \int_{\mathcal{X}} \int_{-\infty}^{r_{\alpha,1}} f(r_1 \mid x, A = 1, D = 1) f(x \mid A = 0, D = 1) dr_1 dx \\
&= \int_{\mathcal{X}} \int_{-\infty}^{r_{\alpha,1}} \frac{f(x \mid A = 0, D = 1)}{f(x \mid A = 1, D = 1)} f(r_1 \mid x, A = 1, D = 1) f(x \mid A = 1, D = 1) dr_1 dx \\
&= E \left\{ \frac{f(X \mid A = 0, D = 1)}{f(X \mid A = 1, D = 1)} \mathbf{1}(R_1 \leq r_{\alpha,1}) \mid A = 1, D = 1 \right\}. \tag{6}
\end{aligned}$$

On the other hand, we can prove that

$$\begin{aligned}
E\{\psi_1(r_{\alpha,1}, W; m, \tilde{m}, e_D, \pi_A)\} &= E[D(1 - A)\{m_1(r_{\alpha,1}, X) - (1 - \alpha)\}] \\
&= E\{P(A = 0, D = 1 \mid X)P(R_1 \leq r_{\alpha,1} \mid X)\} - P(A = 0, D = 1)(1 - \alpha) \\
&= E \left\{ AD \frac{P(A = 0, D = 1 \mid X)}{P(A = 1, D = 1 \mid X)} P(R_1 \leq r_{\alpha,1} \mid X) \right\} - P(A = 0, D = 1)(1 - \alpha) \\
&= \frac{P(A = 0, D = 1)}{P(A = 1, D = 1)} E \left\{ AD \frac{f(X \mid A = 0, D = 1)}{f(X \mid A = 1, D = 1)} P(R_1 \leq r_{\alpha,1} \mid X) \right\} \\
&\quad - P(A = 0, D = 1)(1 - \alpha) \\
&= P(A = 0, D = 1) E \left\{ \frac{f(X \mid A = 0, D = 1)}{f(X \mid A = 1, D = 1)} \mathbf{1}(R_1 \leq r_{\alpha,1}) \mid A = 1, D = 1 \right\} \\
&\quad - P(A = 0, D = 1)(1 - \alpha).
\end{aligned}$$

Combine it with (6), we have $P(R_1 \leq r_{\alpha,1} \mid A = 0, D = 1) = 1 - \alpha + E\{\psi_1(r_{\alpha,1}, W)\} / P(A = 0, D = 1)$.

A.6.3 Proof of Lemma A.1

Lemma A.1. *Under the regularity conditions (A1) and (A2), there exists some constant C_0 such that for any $\delta > 0$,*

$$P\left(|I_1| \leq \frac{C_0 \pi_0 \bar{e}_0 (\underline{e}_0^{-1} + m_0 + \underline{e}_0^{-1} \tilde{m}_0)}{P(A = 0, D = 1)} \sqrt{\frac{\log(1/\delta) + 1}{N}} \mid \mathcal{I}_1\right) \geq 1 - \delta.$$

The proof of Lemma A.1 is adapted from Theorem 3 in Yang et al. (2024). Specifically, we expand the numerator of I_1 into the following four parts,

$$\begin{aligned} & \mathbb{P}\{\widehat{\psi}_1^{(S2)}(r_{\alpha,1}, W)\} - \mathbb{P}_{\mathcal{I}_2}\{\widehat{\psi}_1^{(S2)}(r_{\alpha,1}, W)\} \\ &= \left[\frac{1}{|\mathcal{I}_2|} \sum_{i \in \mathcal{I}_2} \frac{A_i D_i \widehat{\pi}_A(X_i) \widehat{e}_D(X_i, 0) \mathbf{1}(R_1 < r_{\alpha,1})}{\widehat{e}_D(X_i, 1)} - \mathbb{P}\left\{ \frac{AD \widehat{\pi}_A(X) \widehat{e}_D(X, 0)}{\widehat{e}_D(X, 1)} \mathbf{1}(R_1 < r_{\alpha,1}) \right\} \right] \end{aligned} \quad (7)$$

$$+ \frac{1}{|\mathcal{I}_2|} \sum_{i \in \mathcal{I}_2} \{D_i(1 - A_i) - A_i \widehat{\pi}_A(X_i) \widehat{e}_D(X_i, 0)\} \widehat{m}_1(r_{\alpha,1}, X_i) \quad (8)$$

$$\begin{aligned} & - \mathbb{P}\{D(1 - A) - A \widehat{\pi}_A(X) \widehat{e}_D(X, 0)\} \widehat{m}_1(r_{\alpha,1}, X) \\ & + \frac{1}{|\mathcal{I}_2|} \sum_{i \in \mathcal{I}_2} \left\{ A_i \pi_A(X_i) e_D(X_i, 0) - \frac{A_i D_i \pi_A(X_i) e_D(X_i, 0)}{e_D(X_i, 1)} \right\} \widehat{m}_1(r_{\alpha,1}, X_i, S_i) \end{aligned} \quad (9)$$

$$\begin{aligned} & - \mathbb{P}\left\{ A \pi_A(X) e_D(X, 0) - \frac{AD \pi_A(X) e_D(X, 0)}{e_D(X, 1)} \right\} \widehat{m}_1(r_{\alpha,1}, X, S) \\ & - \left\{ \frac{1}{|\mathcal{I}_2|} \sum_{i \in \mathcal{I}_2} D_i(1 - A_i) - P(D = 1, A = 0) \right\} (1 - \alpha) \end{aligned} \quad (10)$$

$$= R_1^{(S2)}(r_{\alpha,1}) + R_2^{(S2)}(r_{\alpha,1}) + R_3^{(S2)}(r_{\alpha,1}) + R_4^{(S2)}.$$

Bound on $\sup_{r_{\alpha,1}} |R_1^{(S2)}(r_{\alpha,1})|$ We define a class of functions \mathcal{F}_1 by

$$\mathcal{F}_1 = \left\{ f_r : f_r = \frac{AD \widehat{\pi}_A(X) \widehat{e}_D(X, 0) \mathbf{1}(R_1 < r_{\alpha,1})}{\widehat{e}_D(X, 1)}, \forall r \right\}.$$

One can observe that $\forall f_r \in \mathcal{F}_1$, we have $|f_r| \leq AD\pi_0\bar{e}_0\underline{e}_0$. Therefore, $AD\pi_0\bar{e}_0\underline{e}_0$ is an envelope function of \mathcal{F}_1 . Let $\|z\|_{\mathcal{F}}$ denote the supremum norm of z over a class of function \mathcal{F} , defined by $\|z\|_{\mathcal{F}} = \sup_{f \in \mathcal{F}} |z(f)|$. For $\mathcal{O}_i = (X_i, A_i, S_i, Y_i, D_i)$ and any function f , we define

$$\mathbb{G}_N = \frac{1}{\sqrt{N}} \sum_{i=1}^N [f(\mathcal{O}_i) - \mathbb{P}\{f(\mathcal{O})\}].$$

Applying Lemma A.2 with $s(a, d, w) = AD\hat{\pi}_A(X)\hat{e}_D(X, 0)/\hat{e}_D(X, 1)$ and $h(w, y) = R_1$ produces $E\|\mathbb{G}_N\|_{\mathcal{F}_1} \leq C_1\pi_0\bar{e}_0\underline{e}_0^{-1}$ with C_1 being a universal constant. By McDiarmid's inequality, we can show that

$$\begin{aligned} P(\|\mathbb{G}_N\|_{\mathcal{F}_1} - E\|\mathbb{G}_N\|_{\mathcal{F}_1} \geq t) &\leq \exp\left(-\frac{2t^2}{\sum_{i=1}^N c_i^2}\right) \\ &\leq \exp\left(-\frac{2t^2}{\sum_{i=1}^N 4\pi_0^2\bar{e}_0^2\underline{e}_0^{-2}/N}\right) = \exp\left(-\frac{t^2}{2\pi_0^2\bar{e}_0^2\underline{e}_0^{-2}}\right), \end{aligned}$$

where

$$\begin{aligned} c_i &\leq \sup_{\mathcal{O}_i, \mathcal{O}'_i} \sup_r \sqrt{N} \left| \frac{1}{N} \frac{A_i D_i \hat{\pi}_A(X_i) \hat{e}_D(X_i, 0)}{\hat{e}_D(X_i, 1)} \mathbf{1}(R_{1,i} < r) \right. \\ &\quad \left. - \frac{1}{N} \frac{A_{i'} D_{i'} \hat{\pi}_A(X_{i'}) \hat{e}_D(X_{i'}, 0)}{\hat{e}_D(X_{i'}, 1)} \mathbf{1}(R_{1,i'} < r) \right| \leq \frac{2\pi_0\bar{e}_0\underline{e}_0^{-1}}{\sqrt{N}}. \end{aligned}$$

Substituting the expectation bound to the inequality gives us

$$P\left(\|\mathbb{G}_N\|_{\mathcal{F}_1} \geq C_2\pi_0\bar{e}_0\underline{e}_0^{-1} \sqrt{1 + \log\left(\frac{1}{\delta}\right)}\right) \leq \delta, \quad (11)$$

for some constant C_2 .

Bound on $\sup_{r_{\alpha,1}} |R_2^{(S_2)}(r_{\alpha,1})|$ Similar to the bound on $\sup_{r_{\alpha,1}} |R_1^{(S_2)}(r_{\alpha,1})|$, a class of function \mathcal{F}_2 is defined by $\mathcal{F}_2 = \{f_r : f_r = \{D(1 - A) - A\hat{\pi}_A(X)\hat{e}_D(X, 0)\} \hat{m}_1(r_{\alpha,1}, X), \forall r\}$, where

$$\begin{aligned} f_r &= \{D(1 - A) - A\hat{\pi}_A(X)\hat{e}_D(X, 0)\} \hat{m}_1(r_{\alpha,1}, X) \\ &= \{D(1 - A) - A\hat{\pi}_A(X)\hat{e}_D(X, 0)\} \int_0^{m_0} \mathbf{1}\{\hat{m}_1(r_{\alpha,1}, X) \geq u\} du \end{aligned}$$

$$= \int_0^{m_0} \{D(1-A) - A\widehat{\pi}_A(X)\widehat{e}_D(X,0)\} \mathbf{1}\{r_{\alpha,1} \geq h(X,u)\} du,$$

where the first equality holds by $\widehat{m}_1(r_{\alpha,1}, X) = \int_0^{m_0} \mathbf{1}\{\widehat{m}_1(r_{\alpha,1}, X) \geq u\} du$, and the second equality holds as $\widehat{m}_1(r_{\alpha,1}, X)$ is monotonously increase in $r_{\alpha,1}$. By Lemma A.2 and McDiarmid's inequality, we have

$$\begin{aligned} E\|\mathbb{G}_N\|_{\mathcal{F}_2} &\lesssim \int_0^{m_0} \max\{1, \pi_0\bar{e}_0\} du \lesssim \pi_0\bar{e}_0 m_0, \\ P(\|\mathbb{G}_N\|_{\mathcal{F}_2} - E\|\mathbb{G}_N\|_{\mathcal{F}_2} \geq t) &\leq \exp\left(-\frac{t^2}{2\pi_0^2\bar{e}_0^2 m_0^2}\right). \end{aligned}$$

Substituting the expectation bound back gives us

$$P\left(\|\mathbb{G}_N\|_{\mathcal{F}_2} \geq C_3\pi_0\bar{e}_0 m_0 \sqrt{1 + \log\left(\frac{1}{\delta}\right)}\right) \leq \delta, \quad (12)$$

for some constant C_3 .

Bound on $\sup_{r_{\alpha,1}} |R_3^{(S_2)}(r_{\alpha,1})|$ Similarly, we first define the class of function \mathcal{F}_3 as

$$\mathcal{F}_3 = \left\{ f_r : \left\{ A\pi_A(X)e_D(X,0) - \frac{AD\pi_A(X)e_D(X,0)}{e_D(X,1)} \right\} \widehat{m}_1(r_{\alpha,1}, X, S) \right\}.$$

The supremum norm of \mathbb{G}_N over \mathcal{F}_3 and the bound of $\|\mathbb{G}_N\|_{\mathcal{F}_3}$ can be obtained by Lemma A.2 and McDiarmid's inequality, respectively:

$$\begin{aligned} E\|\mathbb{G}_N\|_{\mathcal{F}_3} &\lesssim \int_0^{\tilde{m}_0} \pi_0\bar{e}_0(1 - \underline{e}_0^{-1}) du \lesssim \pi_0\bar{e}_0\underline{e}_0^{-1}\tilde{m}_0, \\ P(\|\mathbb{G}_N\|_{\mathcal{F}_3} - E\|\mathbb{G}_N\|_{\mathcal{F}_3} \geq t) &\leq \exp\left(-\frac{t^2}{2\pi_0^2\bar{e}_0^2\underline{e}_0^{-2}\tilde{m}_0^2}\right), \end{aligned}$$

which yields

$$P\left(\|\mathbb{G}_N\|_{\mathcal{F}_3} \geq C_4\pi_0\bar{e}_0\underline{e}_0^{-1}\tilde{m}_0 \sqrt{1 + \log\left(\frac{1}{\delta}\right)}\right) \leq \delta, \quad (13)$$

for some constant C_4 .

Bound on $\sup_{r_{\alpha,1}} |R_4^{(S2)}|$ The random variables $D_i(1 - A_i)$ is i.i.d., and Hoeffding inequality gives us

$$P\left(\left\{\frac{1}{N} \sum_{i=1}^N D_i(1 - A_i) - P(D = 1, A = 0)\right\} \geq t\right) \leq \exp\left(-\frac{2t^2}{N}\right)$$

which leads to

$$P\left(R_4^{(S2)} \geq (1 - \alpha)\sqrt{\frac{1}{2N} \log\left(\frac{1}{\delta}\right)}\right) \leq \delta. \quad (14)$$

Combining (11), (12), (13), and (14) together with the help of union bound, we can show that with probability larger than $1 - \delta$,

$$\sup_r |R_1^{(S2)}(r_{\alpha,1}) + R_2^{(S2)}(r_{\alpha,1}) + R_3^{(S2)}(r_{\alpha,1}) + R_4^{(S2)}| \lesssim \pi_0 \bar{e}_0 (\underline{e}_0^{-1} + m_0 + \underline{e}_0^{-1} \tilde{m}_0) \sqrt{\frac{\log(1/\delta) + 1}{|\mathcal{I}_2|}},$$

which completes the proof for the bound of I_1 . Analogously, we can show that with probability larger than $1 - \delta$,

$$\sup_r |R_1^{(S1)}(r_{\alpha,1}) + R_2^{(S1)}(r_{\alpha,1}) + R_3^{(S1)}| \lesssim \pi_0 \bar{e}_0 \underline{e}_0^{-1} (1 + m_0) \sqrt{\frac{\log(1/\delta) + 1}{|\mathcal{I}_2|}}$$

holds for $\mathbb{P}\{\widehat{\psi}_1^{(S1)}(r_{\alpha,1}, W)\} - \mathbb{P}_{\mathcal{I}_2}\{\widehat{\psi}_1^{(S1)}(r_{\alpha,1}, W)\}$.

A.6.4 Additional lemmas and theorems

Lemma A.2 (Lemma 8, Yang et al. (2024)). *There exists a universal constant C such that for any functions $s(a, d, w) \in [-\kappa_0, \kappa_0]$ and $h(w, y)$,*

$$E\left[\sup_r |\mathbb{G}_N[s(a, d, w)\mathbf{1}\{h(w, y) \leq r\}]|\right] \leq C\kappa_0.$$

Theorem A.1. *Under Assumptions 2-3, the EIF $\psi_0^{(j)}$ for $r_{\alpha,0}$ under Setting j , for $j = S1, S2, S3$, is given, up to a proportionality constant, by*

$$\begin{aligned} \psi_0^{(S1)}(r_{\alpha,0}, W; m, e_D, \pi_A) &= \psi_0^{(S3)}(r_{\alpha,0}, W; m, e_D, \pi_A) = DA\{m_0(r_{\alpha,0}, X) - (1 - \alpha)\} \\ &+ \frac{(1 - A)De_D(X, 1)}{\pi_A(X)e_D(X, 0)}\{\mathbf{1}(R_0 < r_{\alpha,0}) - m_0(r_{\alpha,0}, X)\}, \end{aligned}$$

and

$$\begin{aligned}\psi_0^{(S2)}(r_{\alpha,0}, W; m, \tilde{m}, e_D, \pi_A) &= DA\{m_0(r_{\alpha,0}, X) - (1 - \alpha)\} \\ &+ \frac{(1 - A)e_D(X, 1)}{\pi_A(X)}\{\tilde{m}_0(r_{\alpha,0}, X, S) - m_0(r_{\alpha,0}, X)\} \\ &+ \frac{(1 - A)De_D(X, 1)}{\pi_A(X)e_D(X, 0)}\{\mathbf{1}(R_1 < r_{\alpha,0}) - \tilde{m}_0(r_{\alpha,0}, X, S)\},\end{aligned}$$

where $\tilde{m}_0(r_{\alpha,0}, X, S) = P(R_0 < r_{\alpha,0} \mid X, S, A = 0, D = 1)$, $m_0(r_{\alpha,0}, X) = P(R_0 < r_{\alpha,0} \mid X, A = 0, D = 1)$.

Corollary A.1. *Under Assumptions 2-3, the efficiency gain from observing surrogates in both datasets (Setting 2) compared to only in the source data (Setting 1) in estimating $r_{\alpha,0}$ is given by*

$$V_0^{(S2)} - V_0^{(S1)} = E \left[\frac{1 - e_D(X, 0)}{e_D(X, 0)} \frac{e_D^2(X, 1)\{e_A(X)\}^2}{1 - e_A(X)} \text{var}\{\tilde{m}_0(r_{\alpha,0}, X, S) \mid X, A = 0\} \right],$$

where

$$V_0^{(S1)} = \text{var}\{\psi_0^{(S1)}(r_{\alpha,0}, W; m, e_D, \pi_A)\}, \quad V_0^{(S2)} = \text{var}\{\psi_0^{(S2)}(r_{\alpha,0}, W; m, \tilde{m}, e_D, \pi_A)\}.$$

B Additional Simulation Studies

In this section, we assess the group-conditional performance of the prediction intervals produced by the SCIENCE framework for categorical outcomes. The data generation procedures for X , A , and S remain the same as before, while the potential primary outcomes $Y(a)$ are generated with five levels under the multinomial distribution as follows:

$$\frac{P(Y(a) = k | X, S)}{P(Y(a) = 1 | X, S)} = \exp \left(-\alpha_{Y(a),k} - \sum_{j=1}^2 \frac{X_j}{2} - \sum_{j=1}^2 \frac{S_j(a)}{2} \right)$$

for $k = 2, \dots, 5$, where $k = 1$ serves as the reference level. The parameters $\alpha_{Y(a),k}$ are adaptively chosen to ensure the marginal probabilities are approximately $P(Y(1) = k) = (0.1, 0.2, 0.4, 0.15, 0.15)$ and $P(Y(0) = k) = (0.3, 0.3, 0.2, 0.15, 0.05)$ for $k = 1, \dots, 5$.

The non-conformity scores for categorical outcomes are derived using the nested prediction sets approach from Kuchibhotla and Berk (2023). Let $F_a(W; t) = \{y : P_{Y(a)}(y | W) \leq t\}$ denote a nested sequence of sets constructed based on the first data fold, \mathcal{I}_1 . The associated non-conformity scores $R(W, Y(a))$ are then defined as $R(W, Y(a)) = \inf\{t : y \in F_a(W; t)\}$, where the conditional probabilities are estimated using multinomial logistic regression from the `nnet` package, with or without the inclusion of surrogates. The semi-parametric efficient estimator for the $(1 - \alpha)$ -quantile r_α of $R(W, Y(a))$ is then computed using the second data fold, \mathcal{I}_2 .

Figure 6(A) presents the empirical coverage of the prediction sets at $\alpha = 0.05$ for the observed primary outcomes of both source and target datasets, conditional on the group variable G . The SCIENCE framework that adjusts for the effect of surrogates on the conditional probabilities yields valid empirical coverage for the prediction sets. In contrast, the efficient estimator without surrogates fails to achieve valid empirical coverage, as the conditional probability model marginalized over the surrogates no longer admits the multinomial logistic specification. This misspecification leads to incorrectly constructed non-conformity scores and therefore poor empirical coverage. Figure 6(B) provides the proportions of the size of prediction sets, varying from 1 to 5, conditional on the group variable G . While the prediction sets produced by the efficient estimator without surrogates tend to be smaller than the SCIENCE framework, these smaller sets can be misleading, as

they often fail to contain the true primary outcomes, indicated by their poor coverage.

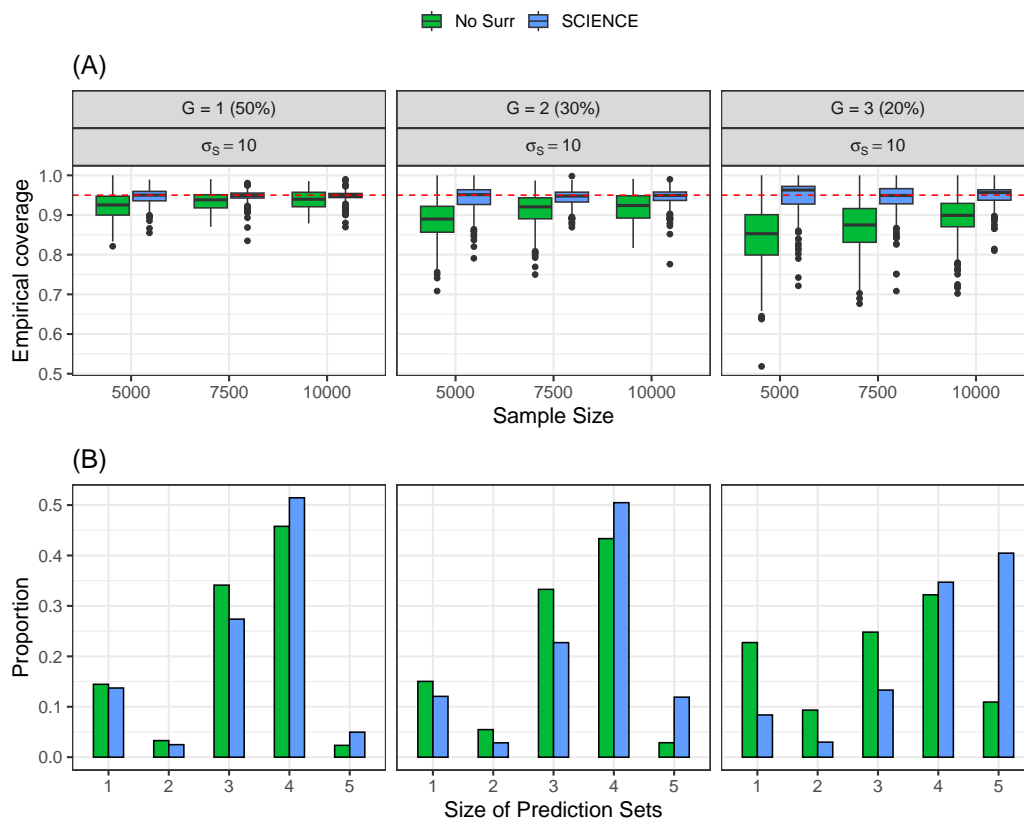

Figure 6: (A) Empirical coverage of the 95% prediction intervals, and (B) the proportions of the size of prediction sets for the ITE of the combined data when $\sigma_S = 10$ and the outcomes are categorical, conditional on the group variable G , across 500 replicates.

C Additional Real Data Analysis

Additional real data results will be included following final review and approval from Moderna.
