Article type: perspective.

Abstract

Superfluorescence in upconversion nanoparticles (UCNPs) is a room-temperature quantum phenomenon which can dramatically increase the rate and overall quantity of photons emitted by neodymium (Nd³⁺) doped UCNPs. This perspective article contextualizes how SF-UCNPs could be exploited as a class of optical nanomaterials for second generation quantum technology applications.

1. Introduction

A second generation quantum technology can be succinctly defined as any technology in which one or more quantum processes — e.g. quantum entanglement, coherence, confinement, spin, etc. — is exploited for the purposes of a second generation quantum technology application, e.g. quantum sensing, quantum imaging, quantum timing, quantum navigation, quantum cryptography, or quantum computing.^{1–12}

Second generation quantum technologies generally tend to have been developed after 1990.⁵ Accompanying these second generation quantum technologies are supporting technologies, such as cooling systems, electronics, production technologies, and optical control systems.^{6,13} Likewise, it is arguable that some optical materials may be regarded as components, or even the core part of a quantum technology. For example, quantum dots (QDs) operating on quantum confinement principals¹⁴ are arguably a first generation quantum technology (i.e. pre-1990s),⁵ which amongst their myriad applications in displays, imaging, and sensing, have subsequently been applied to various second generation quantum technology application areas, e.g. quantum simulation, and quantum computing.^{6,15–19}

Photonic upconversion materials were first developed in bulk form in the 1960s,²⁰ with a subsequent eruption of scientific interest in upconversion nanoparticles (UCNPs) since the mid 2000s.²¹ In brief, upconversion materials consist of a crystalline host structure, such as the commonly utilized sodium yttrium fluoride (NaYF₄).²² In this host lattice are various lanthanide ions which can absorb multiple low-energy photons, such as neodymium, ytterbium, and erbium ions (Nd³⁺, Yb³⁺, and Er³⁺) which absorb at ~800 nm, ~980 nm, and ~1500 nm respectively. These sensitizer ions then non-radiatively transfer energy to various emissive ions, such as erbium and thulium (Er³⁺, Tm³⁺) resulting in emission of a higher-energy photon, typically in the visible wave range.^{22–25} Hence the name “upconversion”, deriving from the upconversion of photon energy.

UCNPs have many attractive practical photonic properties, such as near-infrared and infrared excitation, resistance to photobleaching, physically robust nature, and tunable “line-like” emission. Additionally, their long-lived emission lifetime (typically $\tau \sim 100 - 1000 \mu\text{s}$ arising from $4f \rightarrow 4f$ parity-forbidden lanthanide transitions),^{26,27} can be utilized for time-gated imaging and sensing.^{28,29} Consequently, UCNPs have attracted widespread interest in applications such as temperature sensing,³⁰ pressure sensing,^{30,31} plasmonics,³² photocatalysis,³³ solar cells,³⁴ security inks,^{28,35} data storage,^{36,37} display screens,³⁸ biosensing,³⁹ photodynamic therapy, multi-modal deep-tissue biological imaging,^{29,40} and optogenetics.^{41,42}

Whilst exhibiting many desirable optical properties, UCNPs have the downside of being relatively inefficient optical emitters, with the highest UCNP quantum yield on record being ~9% for core-shell NaYF₄:Yb,Er@NaYF₄ beta-phase UCNPs in dry form.²² As a colloidal suspension in organic solvents or water, the quantum yield of UCNPs is more typically fractions of a percent.^{43,44} In particular, UCNPs are prone to quenching by the OH- vibrations in water molecules.²⁷ In contrast quantum dots (QDs) offer quantum yields in ranges of 25-75% and rhodamine 6G in ethanol has a quantum yield of 95%.^{45,46} This relatively inefficient emission has appeared to be a fundamental limitation of upconversion materials for decades.

Despite the lanthanide-based photophysics of UCNPs being underpinned and described by quantum processes,⁴⁷ UCNPs themselves have typically not meet the criteria to be considered an optical material for second generation quantum technologies due to lack of appropriate quantum processes and appropriate applications (see the first paragraph in this introduction). This is in contrast to related materials, such as polynuclear lanthanide complexes and solid rare earth ion systems, which have been proposed as quantum bits (qubits) for quantum information processing and quantum computing.^{48–50}

Recent demonstrations of a new quantum phenomenon in UCNPs — superfluorescence (SF) — has change how we can consider UCNPs to be quantum optical nanomaterials. SF in UCNPs was first demonstrated by a group of researchers in the USA (Huang et al., 2022),⁵¹ where the SF phenomenon resulted in Nd³⁺ doped UCNPs emitting photons at a rate ~10,000 greater than via conventional upconversion emission processes. Notably SF occurs at room-temperature.⁵¹ A second study has demonstrated that SF can achieve 70x enhancement in UCNP emission intensity.⁵² Therefore SF-UCNPs bypass the fundamental limitations of UCNPs, and SF-UCNPs could be exploited as a second generation quantum technology in any application where an increased photon emission rate and corresponding increase in brightness is advantageous, with obvious utility in sensing and imaging technologies.

2. Superfluorescence in optical materials

SF is a quantum optical phenomena based upon quantum coherence (i.e. the phase stability of a superposition state).⁵³ In SF systems, individual emissive dipoles (normally of a random phase) are coherently coupled to generate a single (phase aligned) large collective macroscopic dipole,

resulting in very fast emission (see Figure 1). This is analogous to a large crowd at a sporting match: normally what any individual is saying cannot be heard clearly – but in the aligned state, i.e. the crowd chanting together (analogous to SF) – the message is very clear!⁵⁴

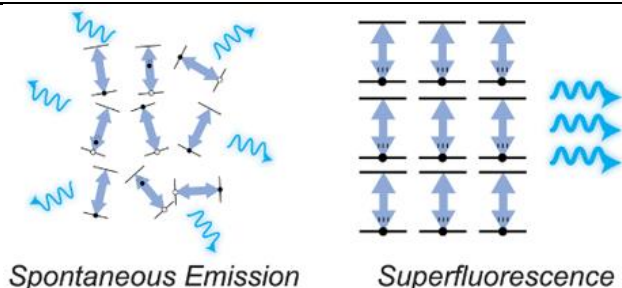

Figure 1. Simple diagram depicting SF. Left: under conventional emission conditions, the phase of each individual dipole emitter (represented by direction of arrow) is randomly aligned. Right: under SF conditions, the phase of many individual dipole emitters is aligned, and so the system acts as a macroscopic giant dipole. Figure reproduced in part from Russ and Eisler (2024)⁵⁴ under a Creative Commons 4.0 International Licence.

SF was first proposed by Dicke in 1954,^{55,56} and was first experimentally demonstrated in 1973.⁵⁷ In typical SF systems, the SF lifetime is proportional to normal emission lifetime of the system divided by the number of phase aligned dipoles, whereas SF emission intensity scales proportionally to the square of the number of aligned dipoles.⁵¹ It has been proposed that SF systems may be of utility for quantum computing, cryptography,⁵⁴ and super-resolution microscopy.⁵²

SF in QDs was first demonstrated experimentally in arrays of many lead halide perovskite QDs by Rainò et al. in 2018.⁵⁸ They showed that colloiddally-synthesized lead halide perovskite QDs can be formed into micrometer sized superlattices arrays via controlled evaporation, and due to coherence effects, these QD superlattices exhibited SF at ultra-low temperatures (i.e. 6K) when excited with a 3.06 eV laser (i.e. ~405 nm) operating at 40 MHz with a pulse duration of 50 ps. Rainò et al.⁵⁸ proposed that SF-QDs could be used for entangled multi-photon quantum light sources.⁵⁸ Zhou et al., (2020)⁵⁹ demonstrated that SF from QD superlattices can be achieved at somewhat higher temperatures (e.g. 77K) using a 400 nm excitation laser (10 kHz, 40 fs pulse width) via appropriate control of the QD superlattice, which they proposed as a “quantum container”.⁵⁹ Based upon our earlier criteria, SF-QDs can be categorized as a second generation quantum technology optical nanomaterial. However, SF-QDs require cryogenic cooling, limiting their application. Notably, room-temperature SF was first demonstrated in hybrid perovskite (CsPbBr₃) systems in a study published in April 2022.⁵³ For a more comprehensive timeline of SF optical materials, readers are referred to a recent excellent review by Russ and Eisler (2024).⁵⁴

3. Experimental demonstrations of SF-UCNPs

SF-UCNPs utilize electromagnetically induced quantum coherence coupling of a large ensemble of photoactive lanthanide ions inside a UCNP into an effective single microscopic dipole, resulting in optical emission on the timescale of ns. To achieve this, a high intensity ns or fs laser pulse at an appropriate wavelength is required to induce the coherence coupling of closely packed emissive ions, by first exciting all ions into an excited state (uncorrelated dipoles of randomly orientated phases), leading to spontaneous emission and subsequent coherent coupling, generating a macroscopic giant dipole, where all dipoles are aligned in phase through a spontaneous synchronization process (see Figure 1). In the case of SF-UCNPs, the emissive ions are closely packed Nd³⁺ ions, which exhibit the required properties, including robustness against dephasing due to thermal and environmental perturbation, and proclivity to Nd³⁺ to Nd³⁺ energy transfer via cross-relaxation processes.^{51,52}

Room-temperature (i.e. 17°C/290K) SF in UCNPs was first demonstrated in a landmark *Nature Photonics* paper published by Huang et al. in July 2022.⁵¹ This research was a collaboration between the USA-based groups of Prof. Gang Han and Prof. Shuang Fang Lim of University of Massachusetts and North Carolina State University respectively. Huang et al. utilized beta-phase⁶⁰ core@shell and core@shell@shell UCNPs produced via the hot injection method and featuring a high proportion of Nd³⁺ ions in either the core or shell layers (see Figure 2). For measurement, the UCNPs were drop cast in a dry form on a quartz glass slide (drop cast via an ethanol solution which was allowed to evaporate). SF excitation was provided by a tuneable optical parametric oscillator (OPO) and diode-pumped solid-state (DPSS) Q-switched pump laser (NT253-1K-SH-H, Ekspla), operating at 800 nm, with a pulse repetition rate of 1 kHz and a pulse width of 4.5 ns. Detection was via a single photon counting detector. The 800 nm wavelength is selected to excited Nd³⁺ ions.^{61–63}

Huang et al, demonstrated SF in Nd³⁺ doped UCNPs where the Nd³⁺ ions were localized exclusively to either the core or shell UCNPs layers (see Figure 2). They noted that Nd³⁺ ions have a favorable coherence state and pack closely, thereby enabling SF. They also proposed an upconversion energy transfer mechanism based upon proximal Nd³⁺ ions, involving ground state absorption, cross relaxation, and excited state absorption processes. They demonstrated that a critical threshold of ~20% Nd³⁺ doping was necessary to achieve SF (due to the proximity of Nd³⁺ ions) and that brighter SF was observed in SF-UCNPs with a high degree of Nd³⁺ doping (i.e. 90%), estimated to correspond to an average of 11 coupled Nd³⁺ dipoles. With conventional continuous wave (CW) laser excitation, these UCNPs exhibited an emission lifetime of 466 μs, whereas the SF-UCNPs studied exhibited an emission lifetime of 46 ns; a ~10,000 fold improvement in emission lifetime. SF-UCNPs was observed at excitation power densities ranging from ~2 to 20 kW/cm². Huang et al., also demonstrated SF emission from clusters of UCNPs and from single UCNPs, observing variations of SF photophysics in SF-UCNP clusters and

noting that SF-UCNPs could be utilized in a wide range of applications.⁵¹

In November 2024, a SF-UCNP study was published by Zhou et al. in *Nature Communications*.⁵² This research was led by Prof. Xueyuan Chen (China). This study built upon and substantially improved SF-UCNP performance. They used beta-phase core@shell UCNPs, produce via the hot injection method. Nd³⁺ was confined to the core of the UCNPs and Nd³⁺ level were varied. At low Nd³⁺ doping levels, these UCNPs had hexagonal plate morphology, but at high Nd³⁺ doping levels, the UCNPs were of a dumbbell morphology (i.e. exposed core with two caps of NaYF₄ (see Figure 2). For measurement, the UCNPs were in a dry form, having been drop-cast onto a glass coverslip via a dilute ethanol dispersion. The SF state was induced by a regeneratively amplified femtosecond Ti-sapphire laser system seeded by a femtosecond Ti-sapphire oscillator (Spitfire Pro-FIKXP, Spectra-Physics). This laser operated at a wavelength of 800 nm, a pulse repetition rate of 1 kHz, a pulse width of 120 fs, and an average energy of 4 mJ per pulse. They noted that being able to fine-tune the laser wavelength is advantageous for optimizing Nd³⁺ excitation. Indeed, this has been reported in prior studies of Nd³⁺ excitation in various materials.^{61–63} SF-UCNP emission detection was via a photomultiplier system.

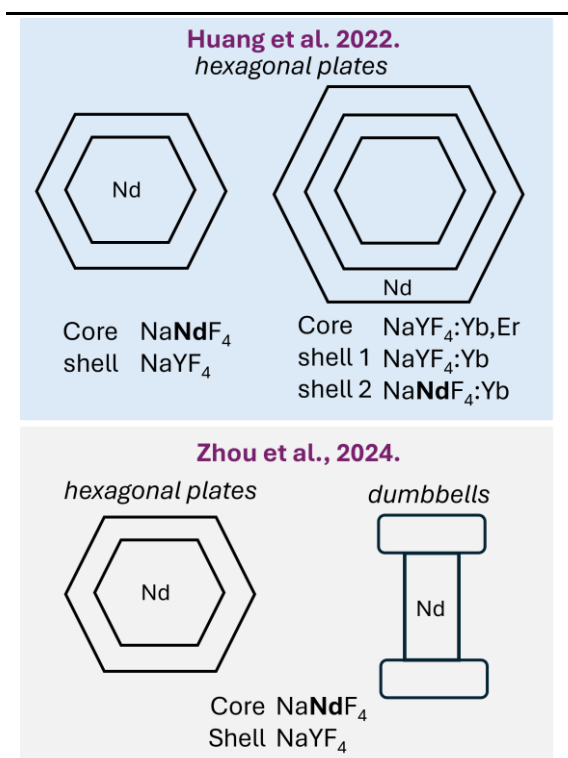

Figure 2. Morphologies of SF-UCNPs demonstrated to-date. Only Nd³⁺ containing core and shell layers are labelled for clarity.^{51,52}

Zhou et al., found that SF was observed in all UCNPs with 25 mol% Nd³⁺ doping or greater, which aligns with the prior findings of a critical Nd³⁺ doping level for SF by Huang et al.^{51,52} Building on this, Zhou et al., found that a Nd³⁺ doping level of 50 mol% in their core@shell UCNPs provided optimal SF at an excitation power density of ~2 kW/cm², postulating that this optimized coherently coupled dipole

formation and dephasing. They reported that they achieved a coherent coupling of 912 Nd³⁺ ions. Under conventional CW excitation, these UCNPs had an emission lifetime of ~2 μs. In their SF state, the SF-UCNPs exhibited an emission lifetime of 2.5 ns, which is an order of magnitude faster than the SF-UCNP lifetime previously demonstrated by Huang et al. (i.e. 46 ns).⁵¹ The SF-UCNP state corresponded to a roughly 70x increase in upconversion emission intensity over conventional CW excitation. Zhou et al., remarked that the number of coupled Nd³⁺ ions (i.e. 912) was limited mainly by their instrumentation. Therefore they expect that it is possible to achieve a greater number of coherently coupled Nd³⁺ ions with future improved instrumentation. Further suggestions were made by Zhou et al., such as SF-UCNPs being used for quantum optics, solid-state single-photon emission, and high-speed high rate super resolution microscopy imaging.⁵²

4. Future prospects and challenges for SF-UCNPs

The room-temperature SF-UCNPs demonstrated by Huang et al. (2022) and Zhou et al. (2024) are initial forays into a new field which will likely attract intense interest from the upconversion nanoparticles, photophysics, and quantum physics research communities. However, there are several practical and scientific challenges that may slow development and application of SF-UCNPs.

1. SF-UCNP research requires coordination and collaboration between (A) skilled chemists to synthesize the sophisticated suitable SF-UCNPs, (B) experimental optical physicists and engineers (to enable optical control), and (C) theoretical physicists to best understand results and propose experiments.
2. The excitation and detection instrumentation currently required for SF-UCNP is very expensive and presents a high barrier of entry to the field. Can more affordable apparatus be found? Certainly that would expedite applications.
3. Do SF-UCNPs have to be produced via the demanding and highly skill hot-injection method, or autoclave and microwave synthesis methods be utilized to make suitable SF-UCNPs?²¹
4. Can SF be generated in other UCNP materials? For example, SF effects have been demonstrated in Er³⁺ doped materials at various temperatures.^{64,65} Therefore, is SF emission possible in Er³⁺ doped UCNPs, such as those recently developed for biological imaging in the second near-infrared window (~1500 nm)?^{66,67}
5. What methods can be used to measure the SF quantum yield (and therefore brightness) of SF-UCNPs? This is challenging even in conventionally excited UCNPs.⁴³ Indeed, this challenge was noted by Zhou et al. in their open peer-review documents co-published with their paper.⁵²
6. What effects temperature have on SF-UCNP emission? Indeed, the group of Prof. Shuang Fang Lim have already explored conventional UCNP temperature dependence between 20 and 70 °C with the same pulsed laser source

used for their SF-UCNP experiments.^{51,68} Further, in their 2022 SF-UCNP paper, they noted that studying temperature dependence could reveal additional insights into photophysics of SF-UCNPs.⁵¹ Therefore the SF-UCNP temperature dependence question may be answered in due course.

7. Could SF-UCNPs be used for pressure sensing?^{30,31} This seems plausible given the SF mechanism is dependent on close packing of Nd³⁺ ions, which will have a pressure dependence.

8. Plasmonic nano-cavities have been shown to induce SF in upconversion materials.⁶⁹ Do SF-UCNP interact with other optical nanomaterials via either plasmonic resonances or fluorescence/luminescence resonance energy transfer (FRET/LRET) in a manner analogous to conventional UCNPs?^{32,70,71}

8. Can SF be generated for UCNPs in a colloidal suspension, i.e. UCNPs in water or an organic solvent? In theory the photoactive core and shell of UCNPs can be protected from solvent quenching by further shell architectures.⁷² Therefore, could suitably designed SF-UCNPs be utilized for liquid applications, such as bio-sensing?

To advance the field, we would welcome discussion of all the above experimental concepts in appropriate formats.

Conclusions

SF in UCNPs is a room temperature quantum optical nanomaterial phenomenon which was demonstrated in UCNPs for the first time in 2022. Whilst many fundamental aspects and practical applications of SF-UCNPs remain to be explored, the prospects of increasing UCNP emission intensity by orders of magnitude beyond conventional excitation is a tantalizing prospect that could enable SF-UCNPs to bypass the limitations of conventional UCNPs and directly compete in terms of brightness against better known high quantum efficiency materials, such as QDs. SF-UCNPs will be of interest for practical applications where higher photon flux is beneficial, such as sensing and imaging. However, there have only been two experimental demonstrations of SF-UCNP emission to-date. Meanwhile, the expense of required instrumentation, and interdisciplinary nature of SF experiments may present considerable barriers to entry to the wider research community. At this early stage of their development, it is expected that SF-UCNPs can be categorized as a nascent second generation quantum optical nanomaterial.

Competing interests

No competing interests to declare.

Funding

L.M. had prior relevant support from the BBSRC [Discovery Fellowship] (BB/T009268/1); The Royal Society of Chemistry [Research Enablement Grant] (E21-5833576777); The Royal Society [Research Grant] (RGS\R1\221139); and The Carnegie Trust [Research Incentive Grant] (RIG013288).

Acknowledgement

Thanks to Dr Luke McLellan for his assistance proof-reading this manuscript.
