Microwave-to-Optical Quantum Transduction with Antiferromagnets

Akihiko Sekine,^{1,*} Ryo Murakami,¹ and Yoshiyasu Doi¹

¹*Fujitsu Research, Fujitsu Limited, Kawasaki 211-8588, Japan* (Dated: December 18, 2024)

The quantum transduction, or equivalently quantum frequency conversion, between microwave and optical photons is essential for realizing scalable quantum computers with superconducting qubits. Due to the large frequency difference between microwave and optical ranges, the transduction needs to be done via intermediate bosonic modes or nonlinear processes. Regarding the transduction mediated by magnons, previous studies have so far utilized ferromagnetic magnons in ferromagnets. Here, we formulate a theory for the microwaveto-optical quantum transduction mediated by antiferromagnetic magnons in antiferromagnets. We derive analytical expressions for the transduction efficiency in the cases with and without an optical cavity, where a microwave cavity is used in both cases. In contrast to the case of the quantum transduction using ferromagnets, we find that the quantum transduction can occur even in the absence of an external static magnetic field. We also find that, in the case with an optical cavity the transduction efficiency takes a peak structure with respect to the sample thickness, indicating that there exists an optimal thickness, whereas in the case without an optical cavity the transduction efficiency is a monotonically increasing function of the sample thickness. Our study opens up a way for possible applications of antiferromagnetic materials in future quantum interconnects.

I. INTRODUCTION

Antiferromagnets have attract attention in the field of spintronics [\[1\]](#page-8-0). Unlike ferromagnets, antiferromagnets do not generate unwanted stray fields because of the zero net magnetization, which can be a merit of utilizing antiferromagnets near the magnetic-field sensitive devices such as superconducting qubits. Moreover, since the dynamics of antiferromagnets such as the antiferromagnetic resonance is typically in the terahertz regime, fast manipulation and utilization of antiferromagnet-based devices are expected. For example, it has been suggested that antiferromagnets can be active elements of a memory [\[2\]](#page-8-1) and logic device [\[3\]](#page-9-0), complementing or replacing ferromagnets.

The quantum transduction, or quantum frequency conversion, between photons at different frequencies is an important quantum technology that enables the interconnects between distant quantum devices. In particular, the quantum transduction between microwave and optical photons is vital for the realization of large-scale quantum computers with superconducting qubits [\[4–](#page-9-1)[6\]](#page-9-2). This is because, optical fibers at the telecom frequency ≈ 200 THz are suitable for long-range quantum state transfer with low loss even at room temperature, while microwaves, by which the superconducting qubits are manipulated, are not suitable for such a purpose. Due to the large frequency difference between the microwave and optical ranges, the quantum transduction needs to be done via intermediate interaction processes between photons and a bosonic mode or via nonlinear interaction processes between photons, such as the optomechanical effect $[7-16]$ $[7-16]$ electro-optic effect $[17–24]$ $[17–24]$, and magneto-optic effect $[25–30]$ $[25–30]$.

The microwave-to-optical quantum transduction via the magneto-optic Faraday effect, i.e., the light-magnon interaction have so far been studied in ferromagnets such as YIG [\[25](#page-9-7)[–30\]](#page-9-8). Such a quantum transduction mediated by ferromagnetic magnons can have a wide bandwidth and can be operated even at room temperature, although there is a room for improvement of the transduction efficiency that is low compared to other transduction methods [\[4–](#page-9-1)[6\]](#page-9-2). Also, the coherent coupling between a ferromagnetic magnon and a superconducting qubit, which is an important step toward the realization of the quantum state transfer between superconducting qubits via optical photon, has been realized [\[31](#page-9-9)[–33\]](#page-9-10).

To the best of our knowledge, the microwave-to-optical quantum transduction utilizing antiferromagnets has not yet been considered. However, a recent experimental study has demonstrated a coherent coupling between microwave cavity photons and antiferromagnetic magnons [\[34,](#page-9-11) [35\]](#page-9-12). Also, a recent theoretical work has studied the coupling between optical cavity photons and antiferromagnetic magnons [\[36\]](#page-10-0). Therefore, we believe that the necessary ingredients for the microwave-to-optical quantum transduction utilizing antiferromagnets are ready to be put together.

In this paper, we study theoretically the quantum transduction between the microwave and optical frequency ranges mediated by antiferromagnetic magnons in antiferromagnets. We derive analytical expressions for the transduction efficiency in the cases with and without an optical cavity, where a microwave cavity is used in both cases. We estimate the magnitude of the transduction efficiency by substituting possible values of the material parameters and the cavity parameters. We also investigate the thickness dependence of the transduction efficiency and find a distinct behavior of the transduction efficiency as a function of the thickness depending on the presence or absence of an optical cavity.

This paper is organized as follows. In Sec. [II](#page-1-0) we introduce a generic lattice model for antiferromagnets with two sublattices and express it in terms of the antiferromagnetic magnon operators. In Sec. [III](#page-1-1) we derive the interaction between microwave cavity photons and antiferromagnetic magnons from the Zeeman interaction in antiferromagnets. In Sec. [IV](#page-2-0) we

[∗] akihiko.sekine@fujitsu.com

derive the interaction between optical cavity photons and antiferromagnetic magnons in the case with an optical cavity, and the interaction between optical itinerant photons and antiferromagnetic magnons in the case without an optical cavity, both from the magneto-optic Faraday effect in antiferromagnets. In Sec. [V,](#page-3-0) starting from a generic description for calculating the transduction efficiency with the input-output formalism, we derive analytical expressions for the transduction efficiency of the microwave-to-optical quantum transduction in the cases with and without an optical cavity. In Sec. [VI](#page-5-0) we present the numerical results for the transduction efficiency. In Sec. [VII](#page-7-0) we briefly discuss a possible experimental realization and the merits of our proposal utilizing antiferromagnets. We also discuss possible ways to improve the transduction efficiency. In Sec. [VIII](#page-8-2) we summarize this study.

II. THEORETICAL MODEL

We study the three-dimensional antiferromagnetic insulators with two sublattices *A* and *B* [see Fig. [1\(](#page-1-2)a)], whose Hamiltonian is described by

$$
H_{\text{AFM}} = J \sum_{\langle i,j \rangle} \mathbf{S}_i \cdot \mathbf{S}_j + |\gamma| \sum_i \mathbf{B}_0 \cdot \mathbf{S}_i - \frac{K_{\parallel}}{2} \sum_i (\mathbf{S}_i^z)^2 + \frac{K_{\perp}}{2} \sum_i (\mathbf{S}_i^x)^2, \tag{1}
$$

where the first through fourth terms are the exchange interaction with $J > 0$ between nearest-neighbor spins, the Zeeman interaction with $B_0 = B_0 e_z$ being an external magnetic field and $|\gamma|$ being is the gyromagnetic ratio, the easy-axis anisotropy with $K_{\parallel} > 0$, the hard-axis anisotropy with $K_{\perp} \geq 0$, respectively.

To quadratic order in the sublattice magnon operators $\hat{a}_{\mathbf{k}}$ and \hat{b}_k in the Holstein-Primakoff transformation [\[37\]](#page-10-1) which satisfy the commutation relations $[\hat{a}_k, \hat{a}_{k'}^\dagger] = \delta_{k,k'}, [\hat{b}_k, \hat{b}_{k'}^\dagger] =$

 (a)

Antiferromagnet

Antiferromagnet

FIG. 1. Schematic illustration of (a) an antiferromagnet with two sublattices of thickness d_{AFI} and (b) the resonance frequencies of an antiferromagnet ($\omega_{\alpha} \ge \omega_{\beta}$) and that of a ferromagnet.

 $\delta_{k,k'}$, $[\hat{a}_k, \hat{a}_{k'}] = 0$, and $[\hat{b}_k, \hat{b}_{k'}] = 0$, it follows that

$$
S_{i\in A}^{+} = \sqrt{2S/N} \sum_{\mathbf{k}} e^{-i\mathbf{k} \cdot \mathbf{r}_{i}} \hat{a}_{\mathbf{k}},
$$

\n
$$
S_{i\in B}^{+} = \sqrt{2S/N} \sum_{\mathbf{k}} e^{-i\mathbf{k} \cdot \mathbf{r}_{i}} \hat{b}_{\mathbf{k}}^{\dagger},
$$

\n
$$
S_{i\in A}^{z} = S - (1/N) \sum_{\mathbf{k}, \mathbf{k}'} e^{-i(\mathbf{k} - \mathbf{k}') \cdot \mathbf{r}_{i}} \hat{a}_{\mathbf{k}}^{\dagger} \hat{a}_{\mathbf{k}'},
$$

\n
$$
S_{i\in B}^{z} = -S + (1/N) \sum_{\mathbf{k}, \mathbf{k}'} e^{-i(\mathbf{k} - \mathbf{k}') \cdot \mathbf{r}_{i}} \hat{b}_{\mathbf{k}}^{\dagger} \hat{b}_{\mathbf{k}'},
$$
 (2)

where *S* is the spin number, *N* is the number of lattice sites in each sublattice, and $S_i^{\pm} = S_i^x \pm iS_i^y$. In order to diagonalize the Hamiltonian [\(1\)](#page-1-3) in terms of magnon operators, we next perform a generalized Bogoliubov transformation [\[38\]](#page-10-2),

$$
\begin{bmatrix}\n\hat{m}_{\alpha,k} \\
\hat{m}_{\beta,-k}^{\dagger} \\
\hat{m}_{\alpha,-k}^{\dagger} \\
\hat{m}_{\alpha,k}^{\dagger}\n\end{bmatrix} = \begin{bmatrix}\nu_{\alpha,a} & \nu_{\alpha,b} & \nu_{\alpha,a} & u_{\alpha,b} \\
\nu_{\beta,a}^* & u_{\beta,b}^* & u_{\beta,a}^* & \nu_{\beta,b}^* \\
\nu_{\alpha,a}^* & u_{\alpha,b}^* & u_{\alpha,a}^* & \nu_{\alpha,b}^* \\
u_{\beta,a} & \nu_{\beta,b} & \nu_{\beta,a} & u_{\beta,b}\n\end{bmatrix} \begin{bmatrix}\n\hat{a}_{\mathbf{k}} \\
\hat{b}_{\mathbf{k}}^{\dagger} \\
\hat{a}_{\mathbf{k}}^{\dagger} \\
\hat{b}_{\mathbf{k}}^{\dagger}\n\end{bmatrix},
$$
\n(3)

or equivalently,

 \sim \sim

$$
\begin{bmatrix}\n\hat{a}_{\mathbf{k}} \\
\hat{b}_{-\mathbf{k}}^{\dagger} \\
\hat{a}_{-\mathbf{k}}^{\dagger} \\
\hat{b}_{\mathbf{k}}\n\end{bmatrix} = \begin{bmatrix}\nu_{a,\alpha} & \nu_{a,\beta} & \nu_{a,\alpha} & u_{a,\beta} \\
\nu_{b,\alpha}^* & u_{b,\beta}^* & u_{b,\alpha}^* & \nu_{b,\beta}^* \\
\nu_{a,\alpha}^* & u_{a,\beta}^* & u_{a,\alpha}^* & \nu_{a,\beta}^* \\
u_{b,\alpha} & \nu_{b,\beta} & \nu_{b,\alpha} & u_{b,\beta}\n\end{bmatrix} \begin{bmatrix}\n\hat{m}_{\alpha,\mathbf{k}} \\
\hat{m}_{\beta,-\mathbf{k}}^* \\
\hat{m}_{\alpha,-\mathbf{k}}^* \\
\hat{m}_{\beta,\mathbf{k}}\n\end{bmatrix},
$$
\n(4)

where the matrix elements in Eq. [\(3\)](#page-1-4) are determined under the condition such that the operators $\hat{m}_{\alpha,k}$ and $\hat{m}_{\beta,k}$ must satisfy the relations $[\hat{m}_{\alpha,\mathbf{k}}, H_{\text{AFM}}] = \hbar \omega_{\alpha,\mathbf{k}} \hat{m}_{\alpha,\mathbf{k}}$ and $[\hat{m}_{\beta,\mathbf{k}}, H_{\text{AFM}}] =$ $\hbar \omega_{\beta,\mathbf{k}} \hat{m}_{\beta,\mathbf{k}}$.

Finally, the original Hamiltonian [\(1\)](#page-1-3) is expressed in a diagonal form in terms of the creation and annihilation operators of antiferromagnetic magnons as

$$
H_{\text{AFM}} = \sum_{\boldsymbol{k}} \left[\hbar \omega_{\alpha,\boldsymbol{k}} \hat{m}_{\alpha,\boldsymbol{k}}^{\dagger} \hat{m}_{\alpha,\boldsymbol{k}} + \hbar \omega_{\beta,\boldsymbol{k}} \hat{m}_{\beta,\boldsymbol{k}}^{\dagger} \hat{m}_{\beta,\boldsymbol{k}} \right], \quad (5)
$$

where α and β denote the two antiferromagnetic magnon modes and k is the wave vector of the magnons. Henceforth we focus on the antiferromagnetic resonance state where all the spins are precessing uniformly (i.e., with $k = 0$) and drop the wave-vector dependence in $\omega_{\mu,k}$ and $\hat{m}_{\mu,k}$. The antiferromagnetic resonance frequencies are given by $\omega_{\alpha,\beta}^2$ = $\omega_E(2\omega_{\parallel} + \omega_{\perp}) + \omega_H^2 \pm \sqrt{\omega_E^2 \omega_{\perp}^2 + 4\omega_H^2 \omega_E(2\omega_{\parallel} + \omega_{\perp})}$ with $\omega_\alpha \ge$ ω_B [\[34,](#page-9-11) [38\]](#page-10-2). Here, the frequencies are given by $\omega_E = JSZ/\hbar$,
 $\omega_H = |\gamma|B_0$, $\omega_H = SK_0/\hbar$, and $\omega_L = SK_0/\hbar$, with Z being $\omega_H = |\gamma| B_0$, $\omega_{\parallel} = S K_{\parallel}/\hbar$, and $\omega_{\perp} = S K_{\perp}/\hbar$, with *Z* being the number of nearest neighbors in the antiferromagnet. A schematic illustration of the magnetic-field dependence of the resonance frequencies ω_{α} and ω_{β} of easy-axis antiferromagnets is shown in Fig. $1(b)$ $1(b)$.

III. MICROWAVE-MAGNON INTERACTION IN ANTIFERROMAGNETS

In this section, following Refs. [\[34,](#page-9-11) [35\]](#page-9-12), we consider the interaction between the antiferromagnetic magnons and microwave cavity photons. Generically, the interaction between the magnetization M and a magnetic field B comes from the Zeeman interaction $M \cdot B$. In the antiferromagnetic resonance state, the spins are precessing around the ground-state direction (the *z* axis in our case). Thus, the small fluctuation of the magnetization density around the ground-state direction $\delta m_{\perp} = \delta m_{x} e_{x} + \delta m_{y} e_{y}$, which is equivalent to the magnon excitation, couples with the applied ac magnetic field. Here, $\delta m_x = S_{i\in A}^x + S_{i\in B}^x$ and $\delta m_y = S_{i\in A}^y + S_{i\in B}^y$.
For concreteness let us consider the ca

For concreteness, let us consider the case of easy-axis antiferromagnets with $K_{\perp} = 0$. In this case, we have [\[39\]](#page-10-3)

$$
u_{a,\alpha} = u_{b,\beta} \equiv U = \frac{1}{\sqrt{2}} \sqrt{\frac{\omega_E + \omega_{\parallel}}{\sqrt{\omega_{\parallel} (2\omega_E + \omega_{\parallel})}} + 1},
$$

$$
v_{a,\beta} = v_{b,\alpha} \equiv V = -\frac{1}{\sqrt{2}} \sqrt{\frac{\omega_E + \omega_{\parallel}}{\sqrt{\omega_{\parallel} (2\omega_E + \omega_{\parallel})}} - 1},
$$
 (6)

and the other coefficients are zero. Then, the explicit forms of the magnetization density components δm_x and δm_y in the antiferromagnetic resonance state is given by

$$
\delta m_x = \sqrt{S/2N}(U+V)\left(\alpha + \alpha^{\dagger} + \beta + \beta^{\dagger}\right),
$$

\n
$$
\delta m_y = (1/i)\sqrt{S/2N}(U+V)\left(\alpha - \alpha^{\dagger} - \beta + \beta^{\dagger}\right)
$$
 (7)

In general, the strength of the easy-axis anisotropy is much smaller than that of the exchange interaction, i.e., $\omega_{\parallel} \ll \omega_E$. In this limit, we get $U + V \approx (\omega_{\parallel}/2\omega_E)^{1/4}$ to leading order in ω[∥]/ω*^E*.

The coupling between microwave photons and antiferromagnetic magnons originates from the Zeeman interaction term in Eq. [\(1\)](#page-1-3): $H_{\text{Zeeman}} = |\gamma| N \delta m_{\perp} \cdot B$. To see this, we consider the quantized magnetic field in a microwave cavity of the form

$$
B(r) = \sum_{n,\lambda} i \cos\left(\frac{n\pi r_j}{L}\right) \sqrt{\frac{\hbar \omega_n \mu_0}{V_c}} \left(\hat{a}_{n\lambda} e_j \times e_\lambda - \hat{a}_{n\lambda}^\dagger e_j \times e_\lambda^*\right),\tag{8}
$$

where we have assumed that the magnetic field is propagating only in the *j* direction. Here, μ_0 is the vacuum permeability, L is the length of the cavity in the *j* direction, V_c is the volume of the cavity, *n* is the frequency mode of the cavity photon, λ denotes the polarization, e_{λ} is the polarization unit vector, and $\hat{a}_{n\lambda}$ is the annihilation operator of a photon with mode *n* and polarization λ .

We assume a magnetic field propagating in the *y* direction √ with a circular polarization basis $e_{\pm} = (e_x \mp i e_z)/\sqrt{2}$. Also, we consider only the lowest-energy cavity mode $n = 1$ with $\omega_1 =$ consider only the lowest-energy cavity mode $n = 1$ with $\omega_1 \equiv$ $\omega_{\rm e}$. Then, the resultant Hamiltonian describing the coupling between microwave photons and antiferromagnetic magnons reads

$$
H_g = \sum_{\lambda = \pm} \sum_{\mu = \alpha \beta} \hbar \lambda g_{\mu} \left(\hat{a}_{\lambda}^{\dagger} \hat{m}_{\mu} + \hat{m}_{\mu}^{\dagger} \hat{a}_{\lambda} \right), \tag{9}
$$

where

$$
g_{\alpha} = g_{\beta} = g_0 \left(\frac{\omega_{\parallel}}{8\omega_E}\right)^{1/4} \sqrt{2SN} \tag{10}
$$

with $g_0 = \eta |\gamma| \sqrt{\hbar \omega_c \mu_0/(4V_c)}$. Here, $\eta \le 1$ is the spatial over-
lan factor between the cavity mode and the antiferromagnet lap factor between the cavity mode and the antiferromagnet and V_c is the volume of the cavity. We note that only the expression for the coupling strength for the lower-energy mode $g_β$ in Eq. [\(10\)](#page-2-1) was obtained in Ref. [\[34\]](#page-9-11).

IV. LIGHT-MAGNON INTERACTION IN ANTIFERROMAGNETS

In this section, we derive the light-magnon interaction in antiferromagnets in the cases with and without an optical cavity, both from the magneto-optic Faraday effect in antiferro-magnets. For concreteness, as in Sec. [III,](#page-1-1) we focus on the easy-axis antiferromagnets with $K_{\perp} = 0$.

A. The case with an optical cavity

First, let us consider the case with an optical cavity. It has been proposed that the interaction between a circularly polarized light propagating in the direction perpendicular to the *z* axis and the antiferromagnetic magnons is described by [\[36\]](#page-10-0)

$$
H_{\zeta} = -\hbar \hat{b}^{\dagger} \hat{b} \left[G_{\alpha} \left(\hat{m}_{\alpha}^{\dagger} + \hat{m}_{\alpha} \right) + G_{\beta} \left(\hat{m}_{\beta}^{\dagger} + \hat{m}_{\beta} \right) \right], \tag{11}
$$

where \hat{b} is the annihilation operator of a photon with a (right or left) circular polarization. If we assume the equivalent Faraday rotation angles for the two sublattices *A* and *B*, the coupling strength G_{μ} ($\mu = \alpha, \beta$) is given by [\[36\]](#page-10-0)

$$
G_{\mu} = \frac{\kappa_{\mu}}{\sqrt{2SN}} \frac{c\theta_{\rm F}}{4\sqrt{\varepsilon}},\tag{12}
$$

where κ_{μ} is determined from the coefficients in the Bogoliubov transformation [\(3\)](#page-1-4), *c* is the speed of light, θ_F is the Faraday rotation angle per unit length, and ε is the relative permittivity of the antiferromagnet. In the case of easy-axis antiferromagnets with $\omega_{\parallel}/\omega_E \ll 1$, we have

$$
\kappa_{\alpha,\beta} = \left(\frac{\omega_{\parallel}}{2\omega_E}\right)^{1/4} \pm K \left(\frac{2\omega_E}{\omega_{\parallel}}\right)^{1/4},\tag{13}
$$

where *K* denotes an intrinsic magneto-optic asymmetry be-tween two sublattices [\[36\]](#page-10-0). Note that the expression for κ_u in Eq. [\(13\)](#page-2-2) is independent of the external magnetic field.

As is well known, the presence of a cavity enhances the coupling strength. To see this, we define the steady-state cavity population as $\bar{n}_{\text{cav}} = \langle \hat{b}^{\dagger} \hat{b} \rangle$. The photon operator can be split into an average coherent amplitude $\langle \hat{b} \rangle$ and a fluctuating term $\delta \hat{b}$ as $\hat{b} = \langle \hat{b} \rangle + \delta \hat{b}$ [\[40\]](#page-10-4). Substituting this expression into Eq. (11) , we obtain

$$
H_{\zeta} = -\hbar \left[\zeta_{\alpha} \left(\hat{m}_{\alpha}^{\dagger} + \hat{m}_{\alpha} \right) + \zeta_{\beta} \left(\hat{m}_{\beta}^{\dagger} + \hat{m}_{\beta} \right) \right] \left(\delta \hat{b}^{\dagger} + \delta \hat{b} \right), \quad (14)
$$

where we have assumed without loss of generality that $\langle \hat{b} \rangle$ is real valued as $\langle \hat{b} \rangle = \sqrt{\bar{n}_{\rm cav}}$ and we have retained only the terms linear in $\delta \hat{b}$. The coupling strength ζ_{μ} ($\mu = \alpha, \beta$) is given by

$$
\zeta_{\mu} = G_{\mu} \sqrt{\bar{n}_{\text{cav}}}.\tag{15}
$$

Typically, the steady-state photon number in an optical cavity can be $\bar{n}_{cav} \sim 10^6$ [\[29\]](#page-9-13). In what follows, we replace $\delta \hat{b}$ by \hat{b} in Eq. (14) for simplicity of notation Eq. [\(14\)](#page-2-4) for simplicity of notation.

B. The case without an optical cavity

Next, let us consider the case without an optical cavity. In this case, we also start with Eq. (11) but consider it in a generalized form [\[36\]](#page-10-0):

$$
H_{\zeta} = -\hbar \left(\hat{b}_{R}^{\dagger} \hat{b}_{R} - \hat{b}_{L}^{\dagger} \hat{b}_{L} \right) \left[G_{\alpha} \left(\hat{m}_{\alpha}^{\dagger} + \hat{m}_{\alpha} \right) + G_{\beta} \left(\hat{m}_{\beta}^{\dagger} + \hat{m}_{\beta} \right) \right], \tag{16}
$$

where $\hat{b}_{R,L}$ is the annihilation operator of a photon with a right circular (left circular) polarization. For concretences let right-circular (left-circular) polarization. For concreteness, let us consider an incident light propagating in the *x* direction (which is a direction perpendicular to the ground-state direction of the magnetic moments). For a strong *z*-polarized light we have $\hat{b}_{R,L}(t) = (\hat{b}_y \mp i\hat{b}_z)/\sqrt{2} \approx (\hat{b}_y \mp i\hat{b}_z)/\sqrt{2}$, where $\hat{c}_{R,L}(t) = \sqrt{B_L/(bQ_L)} e^{-iQ_0 t}$ with $B_L(Q_L)$ the network (engular free $\langle \hat{b}_z \rangle = \sqrt{P_0/(\hbar \Omega_0)} e^{-i\Omega_0 t}$ with $P_0 (\Omega_0)$ the power (angular fre-
 i(\hat{b}_z) = $\sqrt{P_0/(\hbar \Omega_0)} e^{-i\Omega_0 t}$ with $P_0 (\Omega_0)$ the power (angular frequency) of the incident light [\[41\]](#page-10-5). Because in the present case \hat{b} and \hat{b}^{\dagger} represent itinerant photon operators whose dimension is $[\text{time}]^{-1/2}$, the interaction Hamiltonian [\(16\)](#page-3-1) needs to be integrated over the interaction time [\[30\]](#page-9-8).

In order for the interaction time $\tau = d_{\text{AFI}}/c$ with d_{AFI} the thickness of the antiferromagnet to be much shorter than the time scale of the antiferromagnetic dynamics (i.e., the antiferromagnetic resonance frequency) $1/\omega_{\mu} \sim 10^{-12}$ s, the thickness d_{AFI} needs to be of, or shorter than, $O(1 \mu \text{m})$. When this condition is satisfied, the integrand, i.e., the operators in Eq. [\(16\)](#page-3-1) can be regarded as constant during the interaction, enabling the integration over the interaction time as $\int_0^{\tau} dt = \tau$. Then, setting $\hat{b}_y \equiv \hat{b}_{\text{in}}$, we arrive at the interaction Hamiltonian of the form

$$
H_{\xi} = -i\hbar \left[\sqrt{\xi_{\alpha}} \left(\hat{m}_{\alpha}^{\dagger} + \hat{m}_{\alpha} \right) + \sqrt{\xi_{\beta}} \left(\hat{m}_{\beta}^{\dagger} + \hat{m}_{\beta} \right) \right] \times \left(\hat{b}_{\text{in}} e^{i\Omega_{0}t} - \hat{b}_{\text{in}}^{\dagger} e^{-i\Omega_{0}t} \right), \tag{17}
$$

which is indeed the sum of the beam-splitter type and parametric-amplification type interactions representing the Faraday effect [\[25,](#page-9-7) [41\]](#page-10-5). The light-magnon interaction strength ξ_{μ} ($\mu = \alpha, \beta$) is given by

$$
\xi_{\mu} = G_{\mu}^{2} \frac{d_{\text{AFI}}^{2}}{c^{2}} \frac{P_{0}}{\hbar \Omega_{0}} = \frac{\kappa_{\mu}^{2}}{32 \varepsilon} \frac{\phi_{\text{F}}^{2}}{SN} \frac{P_{0}}{\hbar \Omega_{0}}
$$
(18)

with $\phi_F = \theta_F d_{\text{AFI}}$ being the total Faraday rotation angle of the antiferromagnet (which should not be confused with θ_F).

V. MICROWAVE-TO-OPTICAL QUANTUM **TRANSDUCTION**

Having the key ingredients obtained so far, i.e., the strengths of the microwave-magnon interaction and the lightmagnon interaction, we are now in a position to derive the explicit expressions for the transduction efficiency between the microwave range and the optical range in antiferromagnets. The Hamiltonian of the system is given by

$$
H_{\rm sys} = H_0 + H_g + H_{\zeta(\xi)},\tag{19}
$$

where $H_0 = \hbar \omega_e \hat{a}^\dagger \hat{a} + \hbar \delta \omega_o \hat{b}^\dagger \hat{b} + \hbar \omega_a \hat{m}_a^\dagger \hat{m}_a + \hbar \omega_\beta \hat{m}_\beta^\dagger \hat{m}_\beta$ for existence with microwave and optical cavities, while $H_0 =$ systems with microwave and optical cavities, while H_0 = $\hbar \omega_e \hat{a}^\dagger \hat{a} + \hbar \omega_a \hat{m}_\alpha^\dagger \hat{m}_\alpha + \hbar \omega_\beta \hat{m}_\beta^\dagger \hat{m}_\beta$ for systems with a microwave
cavity but without an optical cavity. Here $\delta \omega = \omega_0 - \omega_0$ cavity but without an optical cavity. Here, $\delta \omega_0 \equiv \omega_P - \omega_0$ is the detuning of the optical cavity frequency from the pump frequency [\[29\]](#page-9-13).

A. General consideration

We consider a generic description to obtain an expression for the transduction efficiency [\[6\]](#page-9-2), which can be applied to the setups with and without an optical cavity. Let us define the vectors $\vec{c} = [\hat{a}, \hat{m}_\alpha, \hat{m}_\beta, \hat{b}]^T$, $\vec{c}_{in} = [\hat{a}_{in}, 0, 0, \hat{b}_{in}]^T$, and $\vec{a} = [\hat{a}_{in}, 0, 0, \hat{b}_{in}]^T$ and $\vec{c}_{\text{out}} = [\hat{a}_{\text{out}}, 0, 0, \hat{b}_{\text{out}}]^T$. Here, \hat{a}_{in} and \hat{a}_{out} (\hat{b}_{in} and \hat{b}_{out}) are the incoming and outgoing itinerant microwave (on- \hat{b}_{out}) are the incoming and outgoing itinerant microwave (optical) photons, respectively. Then, the equations of motion $\dot{c}_j = (i/\hbar)[H_{\text{total}}, \hat{c}_j]$, with \hat{c}_j being the *j*-th component of \hat{c} and H_{total} being the total Hamiltonian of the system including the bath Hamiltonian, in the matrix representation can be written in a generic form

$$
\dot{\vec{c}} = -A\vec{c} - B\vec{c}_{\text{in}},\tag{20}
$$

where *A* and *B* are 4×4 matrices. We employ the standard input-output formalism to take into account the presence of the incoming and outgoing itinerant photons, giving rise to

$$
\vec{c}_{\text{out}} = \vec{c}_{\text{in}} + B^T \vec{c}, \qquad (21)
$$

where T is the transpose of a matrix. Combining Eqs. (20) and (21) , the scattering matrix *S* that connects the incoming and outgoing itinerant photons is introduced to obtain

$$
\vec{c}_{\text{out}} = S \, \vec{c}_{\text{in}},\tag{22}
$$

where $S = I_{4\times4} - B^T[-i\omega I_{4\times4} + A]^{-1}B$ with $I_{4\times4}$ being the $A \times A$ identity matrix and we have used the Fourier transform 4×4 identity matrix and we have used the Fourier transform defined by $\vec{c}(t) = \int dt/(2\pi) e^{-i\omega t} \vec{c}(\omega)$. Finally, the microwave-
to-optical transduction efficiency *n* is defined by to-optical transduction efficiency η is defined by

$$
\eta = \left| \frac{\langle \hat{b}_{\text{out}} \rangle}{\langle \hat{a}_{\text{in}} \rangle} \right|^2 = |S_{4,1}|^2 = |S_{1,4}|^2,\tag{23}
$$

with $S_{i,j}$ being an matrix element of S . In a similar way as the transduction efficiency η , we can obtain other quantities from the matrix elements $S_{i,j}$, such as the reflection coefficient for the itingrant microwave mode $S_{i,j}$ ² the itinerant microwave mode $|S_{1,1}|^2$.

B. The case with an optical cavity

First, let us consider the microwave-to-optical quantum transduction in the case with an optical cavity, as schematically depicted in Fig. [2.](#page-4-0) The equations of motion including

FIG. 2. Schematic illustration of our setup for the quantum transduction with microwave and optical cavities in terms of the operators $(\hat{a}_{in},$ $\hat{a}_{\text{out}}, \hat{a}, \hat{m}_{\mu}, \hat{b}, \hat{b}_{\text{in}}$, and \hat{b}_{out}), frequencies $(\omega, \omega_{e}, \omega_{\mu}, \omega_{o}, \text{and } \Omega_{0})$, coupling strengths $(\kappa_{e,e}, g_{\mu}, \zeta_{\mu}, \text{and } \kappa_{o,e})$, and losses $(\kappa_{e,i}, \gamma_{\mu}, \text{and } \kappa_{o,i})$.

losses for the microwave cavity photon \hat{a} , the antiferromagnetic magnons \hat{m}_{μ} ($\mu = \alpha, \beta$), and the optical cavity photon \hat{b} are, respectively,

$$
\dot{\hat{a}} = -i\omega_{\rm e}\hat{a} - i\sum_{\mu}g_{\mu}\hat{m}_{\mu} - \frac{\kappa_{\rm e}}{2}\hat{a} - \sqrt{\kappa_{\rm e,c}}\hat{a}_{\rm in},\tag{24}
$$

$$
\dot{\hat{m}}_{\mu} = -i\omega_{\mu}\hat{m}_{\mu} - ig_{\mu}\hat{a} - i\zeta_{\mu}\hat{b} - \frac{\gamma_{\mu}}{2}\hat{m}_{\mu},\tag{25}
$$

and

$$
\dot{\hat{b}} = -i\delta\omega_0 \hat{b} - i \sum_{\mu} \zeta_{\mu} \hat{m}_{\mu} - \frac{\kappa_0}{2} \hat{b} - \sqrt{\kappa_{0,\text{e}}} \hat{b}_{\text{in}},\tag{26}
$$

where $\kappa_e = \kappa_{e,e} + \kappa_{e,i}$ and $\kappa_o = \kappa_{o,e} + \kappa_{o,i}$. The incoming and outgoing itinerant photons are related by the input-output foroutgoing itinerant photons are related by the input-output formalism as

$$
\hat{a}_{\text{out}} = \hat{a}_{\text{in}} + \sqrt{\kappa_{\text{e,e}}}\hat{a},
$$
\n
$$
\hat{b}_{\text{out}} = \hat{b}_{\text{in}} + \sqrt{\kappa_{\text{o,e}}}\hat{b}.
$$
\n(27)

Combining the above ingredients, the matrices *A* and *B* in Eq. [\(20\)](#page-3-2) are obtained as

$$
A = \begin{bmatrix} i\omega_e + \kappa_e/2 & ig_\alpha & ig_\beta & 0 \\ ig_\alpha & i\omega_\alpha + \gamma_\alpha/2 & 0 & i\zeta_\alpha \\ ig_\beta & 0 & i\omega_\beta + \gamma_\beta/2 & i\zeta_\beta \\ 0 & i\zeta_\alpha & i\zeta_\beta & i\delta\omega_\text{o} + \kappa_\text{o}/2 \end{bmatrix}
$$
(28)

and

$$
B = \begin{bmatrix} \sqrt{\kappa_{e,e}} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \sqrt{\kappa_{o,e}} \end{bmatrix},
$$
(29)

respectively. Finally, introducing the susceptibilities χ_e = $[-i(\omega - \omega_e) + \kappa_e/2]^{-1}$, $\chi_\mu = [-i(\omega - \omega_\mu) + \kappa_\mu/2]^{-1}$, and
 $\chi_e = [-i(\omega - \delta\omega_e) + \kappa_e/2]^{-1}$ the transduction efficiency *n* $\chi_{0} = [-i(\omega - \delta\omega_{0}) + \kappa_{0}/2]^{-1}$, the transduction efficiency η
of the microwave-to-ontical quantum transduction is obtained of the microwave-to-optical quantum transduction is obtained from Eq. (23) as

C. The case without an optical cavity

$$
\eta = \left| \frac{\sqrt{\kappa_{\rm e,e}} \sqrt{\kappa_{\rm o,e}} \left(\zeta_{\beta} g_{\beta} \chi_{\beta} + \zeta_{\alpha} g_{\alpha} \chi_{\alpha} \right)}{\zeta_{\beta}^2 \chi_{\beta} \chi_{\rm e}^{-1} + \zeta_{\alpha}^2 \chi_{\alpha} \chi_{\rm e}^{-1} + \chi_{\rm e}^{-1} \chi_{\rm o}^{-1} + \left(\zeta_{\alpha}^2 g_{\beta}^2 + \zeta_{\beta}^2 g_{\alpha}^2 - 2 \zeta_{\alpha} \zeta_{\beta} g_{\alpha} g_{\beta} \right) \chi_{\alpha} \chi_{\beta} + g_{\beta}^2 \chi_{\beta} \chi_{\rm o}^{-1} + g_{\alpha}^2 \chi_{\alpha} \chi_{\rm o}^{-1}} \right|^2. \tag{30}
$$

When only one of the two antiferromagnetic magnon modes (α or β) is excited, the transduction efficiency η reduces to a simpler expression,

$\eta =$ $\begin{array}{c} \begin{array}{c} \begin{array}{c} \begin{array}{c} \end{array} \\ \end{array} \\ \begin{array}{c} \end{array} \end{array} \end{array} \end{array}$ √ $\frac{\kappa_{e,e}}{2}$ $\frac{\sqrt{\kappa_{e,e}}\sqrt{\kappa_{o,e}}\zeta_{\mu}g_{\mu}}{2\mu\chi_{e}^{-1} + g_{\mu}^{2}\chi_{o}^{-1} + \chi_{\mu}^{-1}\chi_{e}^{-1}\chi_{o}^{-1}}$ ζ $μ$ μ μ μ $\begin{array}{c} \begin{array}{c} \begin{array}{c} \begin{array}{c} \end{array} \\ \end{array} \\ \begin{array}{c} \end{array} \end{array} \end{array} \end{array}$ 2 (31)

with $\mu = \alpha$ or β , which takes the same form as in the case of the microwave-to-optical quantum transduction with ferromagnets [\[6,](#page-9-2) [29\]](#page-9-13).

Next, let us consider the microwave-to-optical quantum transduction in the case without an optical cavity, as schematically depicted in Fig. [3.](#page-5-1) The equations of motion including losses for the microwave cavity photon \hat{a} and the antiferro-

FIG. 3. Schematic illustration of our setup for the quantum transduction with a microwave cavity but without an optical cavity in terms of the operators $(\hat{a}_{\text{in}}, \hat{a}_{\text{out}}, \hat{a}, \hat{m}_{\mu}, \hat{b}_{\text{in}}, \text{and } \hat{b}_{\text{out}})$, frequencies $(\omega, \omega_{e}, \hat{b}_{\text{out}}, \hat{b}_{\text{out}}, \hat{b}_{\text{out}}, \hat{b}_{\text{out}})$, and losses $(\kappa, \hat{b}_{\text{out}}, \hat{b}_{\text{out}}, \hat{b}_{\text{out}}, \hat{b}_{\text{out}}, \hat{b}_{\text{out}})$ $ω_μ$, and $Ω₀$), coupling strengths ($κ_e$, $g_μ$, and $ξ_μ$), and losses ($κ_{e,i}$ and γ_μ).

magnetic magnons \hat{m}_{μ} ($\mu = \alpha, \beta$) are, respectively, ^{[1](#page-5-2)}

$$
\dot{\hat{a}} = -i\omega_{\rm e}\hat{a} - i\sum_{\mu}g_{\mu}\hat{m}_{\mu} - \frac{\kappa_{\rm e}}{2}\hat{a} - \sqrt{\kappa_{\rm e,c}}\hat{a}_{\rm in},\tag{32}
$$

and

$$
\dot{\hat{m}}_{\mu} = -i\omega_{\mu}\hat{m}_{\mu} - ig_{\mu}\hat{a} - \frac{\gamma_{\mu}}{2}\hat{m}_{\mu} - \sqrt{\xi_{\mu}}\hat{b}_{\text{in}},
$$
 (33)

where $\kappa_e = \kappa_{e,e} + \kappa_{e,i}$. The incoming and outgoing itinerant photons are related by the input-output formalism as photons are related by the input-output formalism as

$$
\hat{a}_{\text{out}} = \hat{a}_{\text{in}} + \sqrt{\kappa_{\text{e,e}}}\hat{a},
$$
\n
$$
\hat{b}_{\text{out}} = \hat{b}_{\text{in}} + \sqrt{\xi_{\alpha}}\hat{m}_{\alpha} + \sqrt{\xi_{\beta}}\hat{m}_{\beta}.
$$
\n(34)

Combining the above ingredients, the matrices *A* and *B* in Eq. (20) are obtained as ^{[2](#page-5-3)}

$$
A = \begin{bmatrix} i\omega_{e} + \kappa_{e}/2 & ig_{\alpha} & ig_{\beta} & 0\\ ig_{\alpha} & i\omega_{\alpha} + \gamma_{\alpha}/2 & 0 & 0\\ ig_{\beta} & 0 & i\omega_{\beta} + \gamma_{\beta}/2 & 0\\ 0 & 0 & 0 & 0 \end{bmatrix}
$$
(35)

and

$$
B = \begin{bmatrix} \sqrt{\kappa_{e,e}} & 0 & 0 & 0 \\ 0 & 0 & 0 & \sqrt{\xi_{\alpha}} \\ 0 & 0 & 0 & \sqrt{\xi_{\beta}} \\ 0 & 0 & 0 & 0 \end{bmatrix},
$$
(36)

respectively. Finally, the transduction efficiency η of the microwave-to-optical quantum transduction is obtained from Eq. (23) as

$$
\eta = \left| \frac{\sqrt{\kappa_{e,e}} \left(\sqrt{\xi_{\alpha}} g_{\alpha} \chi_{\alpha} + \sqrt{\xi_{\beta}} g_{\beta} \chi_{\beta} \right)}{g_{\alpha}^2 \chi_{\alpha} + g_{\beta}^2 \chi_{\beta} + \chi_{e}^{-1}} \right|^2.
$$
 (37)

When only one of the two antiferromagnetic magnon modes (α or β) is excited, the transduction efficiency η reduces to a simpler expression,

$$
\eta = \left| \frac{\sqrt{\kappa_{\rm e,e}} \sqrt{\xi_{\mu}} g_{\mu}}{g_{\mu}^2 + \chi_{\mu}^{-1} \chi_{\rm e}^{-1}} \right|^2 \tag{38}
$$

with $\mu = \alpha$ or β , which takes the same form as in the case of the microwave-to-optical quantum transduction with ferromagnets $[6, 25]$ $[6, 25]$ $[6, 25]$.

VI. ESTIMATION OF THE TRANSDUCTION **EFFICIENCY**

So far, we have derived analytical expressions for the transduction efficiency of the microwave-to-optical quantum transduction mediated by antiferromagnetic magnons in antiferromagnets in the cases with and without an optical cavity (where a microwave cavity is used in both cases). In this section, we estimate the magnitude of the transduction efficiency in the cases with and without an optical cavity.

For concreteness, we consider the case of easy-axis antiferromagnetic insulators such as $MnF₂$, as in the previous sections. The spin density of MnF₂ is $SN/V_{AFM} \sim 10^{19}$ mm⁻³ [\[42\]](#page-10-6). Here, V_{AFM} is the sample volume. The exchange and anisotropy frequencies of MnF₂ are $\omega_E/2\pi = 9.3$ THz and $\omega_{\parallel}/2\pi = 0.15$ THz, respectively, and the magneto-optic asymmetry between two sublattices of MnF_2 is $K = 0.007$ [\[43,](#page-10-7) [44\]](#page-10-8). In the following, we use the above values for MnF_2 to obtain the values of g_{μ} , ζ_{μ} , and ξ_{μ} .

It should be noted that the microwave-magnon interaction strength g_{μ} [Eq. [\(10\)](#page-2-1)] depends explicitly on the frequency of the microwave cavity, i.e., the antiferromagnetic resoor the inicrowave cavity, i.e., the antiferromagnetic reso-
nance frequency as $\propto \sqrt{\omega_e}$, while the light-magnon interac-
tion strength ζ . [Eq. (12)] does not. We take as an example tion strength ζ_{μ} [Eq. [\(12\)](#page-2-5)] does not. We take as an example
 ζ_{μ} (2, = ζ_{μ} / $\overline{\zeta_{\mu}}$ with ζ_{μ} = 25 mHz/ ζ_{μ} / $\overline{\zeta_{\mu}}$ = 55 mHz/ ζ_{μ} / $\overline{\zeta_{\mu}}$ = 55 mHz/ ζ_{μ} / $\overline{\zeta_{\mu}}$ = *g*₀/2 π = *A* $\sqrt{\omega_e}$ with *A* = 25 mHz/ $\sqrt{1 \text{ GHz}}$ [\[35\]](#page-9-12). We also assume that $G_{\mu}/2\pi = 0.1\kappa_{\mu}/\sqrt{10^9V_{AFM}/[mm^3]}$ MHz where V_{AFM} is given in units of mm³ [36] V_{AFM} is given in units of mm³ [\[36\]](#page-10-0).

A. The case with an optical cavity

Let us consider the case with an optical cavity. We set $V_{AFM} = (0.1 \text{ mm})^3$. First, we assume that one of the two anti-
ferromagnetic magnon modes (α or β) is excited and the triple ferromagnetic magnon modes (α or β) is excited and the triple resonance condition such that $\omega = \delta \omega_0 = \omega_\mu = \omega_e$ is satisfied. Then, Eq. [\(31\)](#page-4-1) gives rise to an expression for the transduction efficiency in terms of the cooperativities,

$$
\eta = \eta_0 \eta_e \frac{4C_{\text{om},\mu} C_{\text{em},\mu}}{(1 + C_{\text{om},\mu} + C_{\text{em},\mu})^2},\tag{39}
$$

where $\mu = \alpha$ or β , $\eta_0 = \kappa_{0,e}/\kappa_0$, $\eta_e = \kappa_{e,e}/\kappa_e$, and $C_{em,\mu} =$ $4g_\mu^2/(\kappa_e \gamma_\mu)$ and $C_{\text{om},\mu} = 4\zeta_\mu^2/(\kappa_o \gamma_\mu)$ are the cooperativity be-
tween microwave photon and magnon and the cooperativity tween microwave photon and magnon and the cooperativity between optical photon and magnon, respectively. Eq. [\(39\)](#page-5-5)

¹ The factor $e^{\pm i\Omega_0 t}$ in Eq. [\(17\)](#page-3-5) can be eliminated when performing the Fourier transform as follows: $e^{i\Omega_0 t} \hat{b}_{\text{in}}(t) = \int (d\omega/2\pi) \hat{b}_{\text{in}}(\omega) e^{-i(\omega-\Omega_0)t}$ $\hat{m}_{\mu}(t) = \int (d\omega/2\pi) \hat{m}_{\mu}(\omega) e^{-i\omega t} = \int (d\omega/2\pi) \hat{m}_{\mu}(\omega - \Omega_0) e^{-i(\omega-\Omega_0)t}$, and $\hat{a}(t) = \int (d\omega/2\pi) \, \hat{a}(\omega)e^{-i\omega t} = \int (d\omega/2\pi) \, \hat{a}(\omega - \Omega_0) e^{-i(\omega - \Omega_0)t}$.
In this case, we need to put a dummy constant Λ in the matrix

² In this case, we need to put a dummy constant Δ in the matrix element $A_{4,4}$, of Eq. (35) to obtain the inverse matrix of Δ . The final expression for n of Eq. (35) to obtain the inverse matrix of *A*. The final expression for η does not depend on ∆.

coincides with a generic expression for the transduction efficiency mediated by one intermediate bosonic mode [\[6\]](#page-9-2). To estimate the magnitude of the transduction efficiency from Eq. [\(39\)](#page-5-5), suppose that the lower-frequency magnon mode with $\omega_{\beta}/2\pi = 20$ GHz is excited in an easy-axis antiferromagnet, as experimentally realized [\[35\]](#page-9-12). We use the following possible values of parameters: $g_\beta/2\pi \approx 3.3 \text{ MHz}, \zeta_\beta/2\pi \approx 40 \text{ kHz}$ (with $\kappa_{\beta} \approx 0.4$ and $\bar{n}_{\text{cav}} \approx 1 \times 10^6$), $\gamma_{\beta}/2\pi \approx 100 \text{ MHz}$, $\kappa / 2\pi = \kappa / 2\pi \approx 100 \text{ MHz}$, and $\kappa / 2\pi = \kappa / 2\pi \approx 100 \text{ MHz}$. $\kappa_{0,i}/2\pi$ = $\kappa_{0,e}/2\pi \approx 100 \text{ MHz}$, and $\kappa_{e,i}/2\pi = \kappa_{e,e}/2\pi \approx$ 100 MHz [\[29,](#page-9-13) [35,](#page-9-12) [36\]](#page-10-0). Substituting these possible values into Eq. [\(39\)](#page-5-5), the magnitude of the transduction efficiency is estimated to be

$$
\eta \sim 10^{-9},\tag{40}
$$

which is about an order of magnitude smaller than the transduction efficiency utilizing the ferromagnet YIG [\[29\]](#page-9-13). This is mainly due to the fact that YIG has a quite small magnon decay rate of $\gamma_m \approx 1$ MHz, resulting in a higher transduction efficiency.

Next, we turn to the case when the resonance frequencies of the two antiferromagnetic magnon modes are degenerate, which can be realized at zero magnetic field in easyaxis antiferromagnets. Taking MnF_2 as an example, we have $\omega_{\alpha}/2\pi = \omega_{\beta}/2\pi \approx 250$ GHz at $B_0 = 0$ [\[39\]](#page-10-3). In this case, it is not easy to obtain a simpler expression even when the quadruple resonance condition $\omega = \delta \omega_0 = \omega_\alpha = \omega_\beta = \omega_e$ is satisfied. Here, it is important to note that both the microwavemagnon interaction strength g_{μ} and light-magnon interaction strength ζ_μ can be, in general, different depending on the antiferromagnetic magnon mode. In easy-axis antiferromagnets, which we are focusing on here, we have $\zeta_{\alpha} \neq \zeta_{\beta}$ [see Eq. [\(13\)](#page-2-2)] whereas $g_\alpha = g_\beta$ [see Eq. [\(10\)](#page-2-1)]. For example, it has been estimated that $\kappa_{\alpha,\beta} \approx 0.5, 0.4$ [Eq. [\(13\)](#page-2-2)] in the easy-axis antiferromagnet MnF_2 [\[36\]](#page-10-0). We use the following possible values of parameters: $g_{\alpha}/2\pi = g_{\beta}/2\pi \approx 10$ MHz, $\zeta_{\alpha}/2\pi \approx 50 \text{ kHz}, \, \zeta_{\beta}/2\pi \approx 40 \text{ kHz}$ (with $\bar{n}_{\text{cav}} \approx 1 \times 10^6$),
 $\gamma_{\alpha}/2\pi = \gamma_{\alpha}/2\pi \approx 1000 \text{ MHz}$ $\kappa_{\alpha}/2\pi = \kappa_{\alpha}/2\pi \approx 100 \text{ MHz}$ $\gamma_{\alpha}/2\pi = \gamma_{\beta}/2\pi \approx 1000 \text{ MHz}, \kappa_{0,i}/2\pi = \kappa_{0,e}/2\pi \approx 100 \text{ MHz},$ and $\kappa_{e,i}/2\pi = \kappa_{e,e}/2\pi \approx 500 \text{ MHz}$ [\[29,](#page-9-13) [35,](#page-9-12) [36\]](#page-10-0). Here, we have assumed that the magnon decay rates (γ_α and γ_β) and the microwave cavity decay rates ($\kappa_{e,i}$ and $\kappa_{e,e}$) become larger as the antiferromagnetic resonance frequency becomes larger, as in the case of ferromagnets. Substituting these possible values into Eq. [\(30\)](#page-4-2), the transduction efficiency is estimated to be

$$
\eta \sim 10^{-10}.\tag{41}
$$

Note that the smallness of this value compared to Eq. [\(40\)](#page-6-0) is due to the above assumption that the decay rates become larger as the antiferromagnetic resonance frequency become larger. Similar magnitudes of the transduction efficiency to Eq. [\(41\)](#page-6-1) are also obtained when only the higher-frequency magnon mode with $\omega_{\alpha}/2\pi \sim 10^2$ GHz is excited.

B. The case without an optical cavity

Let us consider the case without an optical cavity. Recall that the thickness of the antiferromagnet d_{AFM} should be of, or

shorter than, $O(1 \mu m)$ (see Sec. [IV B\)](#page-3-6). Hence, we set V_{AFM} = $(0.1 \text{ mm})^2 \times 1 \mu \text{m}$ with $d_{AFM} = 1 \mu \text{m}$. First, we assume that one of the two antiferromagnetic magnon modes (α or β) is excited and the double resonance condition such that $\omega = \omega_{\mu} = \omega_{\rm e}$ is satisfied. Then, Eq. (38) gives rise to an expression for the transduction efficiency in terms of the cooperativity,

$$
\eta = \eta_{\rm e} \eta_{\rm m,\mu} \frac{4C_{\rm em,\mu}}{(1 + C_{\rm em,\mu})^2},\tag{42}
$$

where $\mu = \alpha$ or β , $\eta_{m,\mu} = \xi_{\mu}/\gamma_{\mu}$, and the other quantities have been defined in Eq. [\(39\)](#page-5-5). As in the case with an optical cavity, Eq. [\(42\)](#page-6-2) coincides with a generic expression for the transduction efficiency mediated by one intermediate bosonic mode [\[6\]](#page-9-2). To estimate the magnitude of the transduction efficiency from Eq. [\(42\)](#page-6-2), suppose that the lower-frequency magnon mode with $\omega_{\beta}/2\pi = 20$ GHz is excited in an easy-axis antiferromagnet, as experimentally realized [\[35\]](#page-9-12). We use the following possible values of parameters: $g_\beta/2\pi \approx 0.33 \text{ MHz}$, $\gamma_{\beta}/2\pi \approx 100 \text{ MHz}$, and $\kappa_{\text{e,i}}/2\pi = \kappa_{\text{e,e}}/2\pi \approx 100 \text{ MHz}$ [\[35\]](#page-9-12). As for the light-magnon interaction strength [Eq. [\(18\)](#page-3-7)], we assume that $P_0 = 15$ mW and $\Omega_0/2\pi = 193$ THz, which gives rise to $\xi_{\beta}/2\pi \approx 2.1 \times 10^{-7}$ Hz. Substituting these possible values into Eq. [\(42\)](#page-6-2), the transduction efficiency is estimated to be

$$
\eta \sim 10^{-19}.\tag{43}
$$

The smallness of this value results from the small lightmagnon interaction strength ξ_{β} , i.e., the smallness of $\eta_{m,\beta} \sim$ 10^{-15} , as can be seen that the transduction efficiency η is proportional to $\eta_{m,\beta}$ in Eq. [\(42\)](#page-6-2).

When the resonance frequencies of the two antiferromagnetic magnon modes are degenerate, or when the higherfrequency magnon mode with $\omega_{\alpha}/2\pi \sim 10^2$ GHz is excited, the magnon decay rates γ_α and γ_β would be larger than those in the frequency range of $\omega_{\mu} \sim 10^{1}$ GHz (see Sec. VIA). Then, the magnitude of the transduction efficiency would become lower than Eq. [\(43\)](#page-6-3). This is because the magnitude of the transduction efficiency in the form of Eq. (43) is essentially determined by the magnitude of $\eta_{m,\beta}$, as has been discussed in the case of ferromagnets [\[25,](#page-9-7) [30\]](#page-9-8).

C. Thickness dependence

Here, we investigate the thickness dependence of the transduction efficiency in the cases with and without an optical cavity. To this end, we parametrize the sample thickness d_{AFM} [mm] and set the sample volume as $V_{\text{AFM}} = (0.1 \text{ mm})^2 \times$ d_{AFM} . Then, assuming that the lower-frequency magnon mode with $\omega_\beta/2\pi = 20$ GHz is excited in an easy-axis antiferromagnet and using the parameters introduced in Secs. [VI A](#page-5-7) and

FIG. 4. (a) Thickness d_{AFM} dependence of the transduction efficiency η in the case with an optical cavity. (b) Thickness d_{AFM} dependence of the transduction efficiency η in the case without an optical cavity. Note that in (b) the transduction efficiency η is defined when the thickness d_{AFM} is of, or shorter than, $O(10^{-3}$ mm), whereas in (a) there is no restriction on the value of d_{AFM} .

VIB, we obtain

$$
g_{\beta} \approx 10.5 \times \sqrt{\frac{d_{\text{AFM}}}{[mm]}} \text{MHz},
$$

\n
$$
\zeta_{\beta} \approx 1.3 \times 10^{-2} / \sqrt{\frac{d_{\text{AFM}}}{[mm]}} \text{MHz},
$$

\n
$$
\zeta_{\beta} \approx 2.1 \times 10^{-10} \times \frac{d_{\text{AFM}}}{[mm]} \text{MHz}.
$$
 (44)

Here, note that one can consider directly the sample volume *V*AFM dependence instead of the thickness dependence. Of course, these two parameters are essentially equivalent.

As shown in Fig. [4,](#page-7-1) we find a distinct behavior of the transduction efficiency η as a function of the thickness d_{AFM} depending on the presence or absence of an optical cavity. First, we show the result for the case with an optical cavity in Fig. $4(a)$ $4(a)$. In this case, we see that there exists an optimal value of the thickness $d_{AFM} \sim O(10^{-3} \text{ mm})$ at which the transduction efficiency takes a maximum value. This result can be understood as follows. When the value of d_{AFM} is small, the effect of the light-magnon interaction $\zeta_{\beta} \propto 1/\sqrt{d_{\text{AFM}}}$, which
is an decreasing function of d_{AFM} is dominant, and thus the is an decreasing function of d_{AFM} , is dominant, and thus the transduction efficiency scales as $\eta \sim C_{\text{cm}}^{-1} \sim d_{\text{AFM}}$. On the other hand, when the value of d_{AFM} is large, the effect of the other hand, when the value of d_{AFM} is large, the effect of the microwave-magnon interaction $\xi_{\beta} \propto \sqrt{d_{\text{AFM}}}$, which is an in-
creasing function of d_{AFM} is dominant, and thus the transduccreasing function of d_{AFM} , is dominant, and thus the transduc-

FIG. 5. Schematic illustration of our experimental setup for the microwave-to-optical quantum transduction without an optical cavity. A static magnetic field is applied along the easy axis of the antiferromagnet. A linearly polarized laser with the frequency of 193 THz is applied perpendicular to the easy axis of the antiferromagnet.

tion efficiency scales as $\eta \sim C_{\text{em},\beta}^{-1} \sim d_{\text{AFM}}^{-1}$.
Next we show the result for the case with

Next, we show the result for the case without an optical cavity in Fig. [4\(](#page-7-1)b). In this case, we see that the transduction efficiency is a monotonically increasing function of the thickness $d_{\rm AFM}$. This result can be understood from that both the lightmagnon interaction ξ_{β} and the microwave-magnon interaction g_B are increasing functions of d_{AFM} , and thus the transduction is also an increasing function of d_{AFM} .

Finally, we note that the above distinct behavior of the transduction efficiency with respect to the sample thickness depending on the presence or absence of an optical cavity will also be observed when utilizing ferromagnets, since both the microwave-magnon and light-magnon interaction strengths in ferromagnets have the same sample thickness dependences as Eq. [\(44\)](#page-7-2) [\[25,](#page-9-7) [30,](#page-9-8) [45\]](#page-10-9) [see also Eq. [\(10\)](#page-2-1) and Eqs. [\(12\)](#page-2-5) and [\(18\)](#page-3-7), respectively].

VII. DISCUSSION

Let us briefly discuss a possible experimental setup of the microwave-to-optical quantum transduction utilizing antiferromagnets. A schematic illustration of our experimental setup for the case without an optical cavity is shown in Fig. [5.](#page-7-3) For concreteness, we show the case of an easy-axis antiferromagnet where only one of the two antiferromagnetic magnon modes (α or β) is excited. A static magnetic field is applied along the easy axis and a linearly polarized laser with the frequency of 193 THz is applied perpendicular to the easy axis. On the other hand, when we take into account an optical cavity, we can for example use an optical waveguide as has been used for the microwave-to-optical quantum transduction utilizing the ferromagnet YIG [\[29\]](#page-9-13). As we have considered in Sec. [IV A,](#page-2-6) the light needs be applied perpendicular to the easy axis.

One of the merits of utilizing antiferromagnets for the microwave-to-optical quantum transduction is the wide frequency tunability of the microwave cavity frequency (corresponding to the antiferromagnetic resonance frequency), ranging from $O(1 \text{ GHz})$ to $O(1 \text{ THz})$. This means that a variety of quantum devices that operate at these frequencies can be interconnected via the quantum transducer utilizing antiferromagnets. Another merit would be the operating temperature of $O(100 \text{ K})$ of the quantum transduction higher than those of other transduction methods using the optomechanical and electro-optic effects [\[4–](#page-9-1)[6\]](#page-9-2), originating from the fact the antiferromagnetic resonance can occur at $O(100 \text{ K})$. (Note that this merit also applies to the case of ferromagnets.)

The magnitudes of the transduction efficiency we have estimated so far are not sufficient for practical use as a quantum transducer, since it has been suggested theoretically that $\eta = 0.5$ is the lower limit for realizing the quantum state transfer between quantum devices [\[4](#page-9-1)[–6\]](#page-9-2). Let us consider possible ways of improving the transduction efficiency. As we have seen in Secs. [VI A](#page-5-7) and [VI B,](#page-6-4) in both cases with and without an optical cavity the transduction efficiency gets improved as the magnon decay rate becomes smaller. Thus, utilizing antiferromagnets with a low magnon decay rate is one possible direction. Another direction may be to utilize the heterostructures consisting of an antiferromagnet and a nonmagnetic insulator, in a similar way to the topological insulator heterostructures [\[30\]](#page-9-8). Here, we take a look at the case with an optical cavity, because there is a sample size limitation in the case without an optical cavity where there is no limitation in the case with an optical cavity (see Sec. [IV B\)](#page-3-6). For a heterostructure of N_L antiferromagnet layers and N_L nonmagnetic insulator layers, the microwave-magnon and light-magnon interaction strengths microwave-magnon and light-magnon interaction stre
are modified as $g_{\mu} \to \tilde{g}_{\mu} = g_{\mu} \sqrt{N_{L}}$ and $\zeta_{\mu} \to \tilde{\zeta}_{\mu} = \zeta_{\mu}$
respectively. This is because the magnon operators are ng *N*L, respectively. This is because the magnon operators are modified as $\hat{m}_{\mu} \to \hat{m}_{\mu} = \frac{1}{\sqrt{N_{\mu}}} \sum_{i=1}^{N_{\rm L}} \hat{m}_{i,\mu}$, where $\hat{m}_{i,\mu}$ is the magnon operator of the *i*-th antiferromagnet layer and \hat{m}_{μ} is the collective magnon operator satisfying the commutation relation $[\hat{m}_{\mu}, \hat{m}_{\mu}^{\dagger}] = 1$ [\[30\]](#page-9-8). Then, we find that the transduction effi-
ciency *n* [Eq. (39)] in the triple resonance condition scales as ciency η [Eq. [\(39\)](#page-5-5)] in the triple resonance condition scales as $\eta \sim N_L^2$, since with the parameters we have used in this study
the cooperativities are small so that $n \sim C$ and Γ_R (39) the cooperativities are small so that $\eta \sim C_{\text{om},\mu} C_{\text{em},\mu}$ in Eq. [\(39\)](#page-5-5). If a heterostructure with N_L = 5000 and d_{AFM} = 1 μ m (the thickness of each layer) is possible, then the transduction efficiency is improved from $\eta \sim 10^{-9}$ [Eq. [\(40\)](#page-6-0)] to

$$
\eta \sim 10^{-2},\tag{45}
$$

which is comparable to the current achievements in optomechanical and electro-optic systems [\[4–](#page-9-1)[6\]](#page-9-2).

Finally, we mention a recent study on a microwave-to-

optical quantum transduction using antiferromagnetic topo-logical insulators [\[46\]](#page-10-10). The quantum transduction studied in Ref. [\[46\]](#page-10-10) is based on a strong nonlinear optical interaction via spin-orbit coupling, which gives rise to the effective Hamiltonian of the form $H_{int} = \hbar \mathcal{G}(\hat{a}^\dagger \hat{b} + \hat{b}^\dagger \hat{a})$, where \hat{a} and \hat{b} are the annihilation operator of microwave and optical photons, respectively. This mechanism is similar to that of the quantum transduction via the electro-optic effect, which is thus different from ours, i.e., the quantum transduction via the intermediate bosonic mode.

VIII. SUMMARY

To summarize, we have formulated a theory for the microwave-to-optical quantum transduction mediated by antiferromagnetic magnons in antiferromagnets. We have derived analytical expressions for the transduction efficiency in the cases with and without an optical cavity, where a microwave cavity is used in both cases. The derived expressions for the transduction efficiency take complicated forms when the two antiferromagnetic magnon modes coexist, while they reduce to the same expressions as in the case utilizing ferromagnets when one of the two antiferromagnetic magnon modes are excited. We have found that the quantum transduction can occur even in the absence of an external static magnetic field, which is in contrast to the case of the quantum transduction using ferromagnets where an external static magnetic field is essential to cause the resonance state. We have also found that, in the case with an optical cavity the transduction efficiency takes a peak structure with respect to the sample thickness, indicating that there exists an optimal thickness, whereas in the case without an optical cavity the transduction efficiency is a monotonically increasing function of the sample thickness. It is expected that by utilizing a heterostructure consisting of an antiferromagnet and a nonmagnetic insulator the transduction efficiency can be improved to the magnitude that is comparable to the up-to-date values achieved so far in optomechanical and electro-optic systems. Owing to the wide tunability of the antiferromagnetic resonance frequency, it is expected that a variety of quantum devices that operate at the wide frequency ranges from $O(1 \text{ GHz})$ to $O(1 \text{ THz})$ can be interconnected via the quantum transducer utilizing antiferromagnets. Our study opens up a way for possible applications of antiferromagnetic materials in future quantum interconnects.
