As one class of typical quantum materials, Kagome metals in  $AV_3Sb_5(A = K, Rb, Cs)$  have attracted extensive attentions due to their interesting physical properties and different quantum phases of charge density wave (CDW), superconductivity and nontrivial topology. Recently, a new CDW phase in  $ScV_6Sn_6$  was experimentally observed and inspired a wide study of the mechanism of driving force. To have a clear understanding of the correlation effect in the CDW phase in  $ScV_6Sn_6$ , we performed a systematic density functional theory plus dynamical mean field theory (DFT + DMFT) calculations. The resulting static local spin susceptibility is nearly independent of temperature, indicating the absence of local moment on atom V, in full agreement with experimental measurements. The mass enhancements of quasiparticles and bandwidth renormalizations near the Fermi level show a weak correlation strength in  $ScV_6Sn_6$ . In addition, the comparable mass enhancements of quasiparticles in  $ScV_6Sn_6$  with CDW order and  $YV_6Sn_6$  without CDW phase suggests that electronic correlations corresponding to Fermi surface nesting do not play the dominant role in the formation of CDW order in  $ScV_6Sn_6$ .

## I. INTRODUCTION

Kagome lattice has received significant attention in last decades due to its fundamental symmetry and physics, which often present as linear band crossing, saddle point, and flat band, etc[\[1–](#page-4-0)[8\]](#page-5-0). In recent years, much effort has been devoted to the study of these characteristic features present by Kagome lattice in real materials and impressive progresses have been made in this direction. For example, linear band crossings and flat bands in paramagnetic CoSn [\[9,](#page-5-1) [10\]](#page-5-2) and antiferromagnetic FeSn [\[11,](#page-5-3) [12\]](#page-5-4), and saddle points generated van Hove singularity in anti-ferromagnetic YMn<sub>6</sub>Sn<sub>6</sub> [\[13\]](#page-5-5) and paramagnetic  $GdV_6Sn_6$ [\[14\]](#page-5-6). These realistic materials provide practical platforms for the study of the novel quantum phases, such as the anomalous Hall effect, topological band structure, flat bands, as well as fractional quantum Hall effect, etc.

In addition, some other interesting properties were found in Kagome metals. A series of Kagome metals in  $AV_3Sb_5$  ( $A = K$ , Rb, Cs) were discovered to exhibit superconductivity at low temperatures ranging from 0.9 to 2.5 K [\[15–](#page-5-7)[17\]](#page-5-8). Moreover, charge density wave (CDW) transitions at temperatures between 80 and 100 K were also observed in these systems[\[15–](#page-5-7)[22\]](#page-5-9), and van Hove singularity was believed to be one of the most important prequirements [\[23–](#page-5-10)[34\]](#page-6-0). Very recently, a long-range CDW order of  $q_{CDW} = (1/3, 1/3, 1/3)$  was observed in ScV<sub>6</sub>Sn<sub>6</sub> below 92 K, where the Kagome lattice constituted of atoms V [\[37\]](#page-6-1), the same as  $AV_3Sb_5$  ( $A = K$ , Rb, Cs). However, the CDW order in  $ScV_6Sn_6$  is mainly caused by the out-plane charge density modulation [\[37\]](#page-6-1), which contrasts with  $AV_3Sb_5$  (A = K, Rb, Cs) but coincide with FeGe. To date, several theoretical framework to explore

the origin of the CDW order in  $ScV_6Sn_6$ . According to current understanding, Fermi surface nesting (FSN) was ruled out by density functional theory (DFT) calculations [\[38,](#page-6-2) [39\]](#page-6-3) and a giant q-dependent electron-phonon coupling has been proposed as an underlying mechanism [\[40\]](#page-6-4). However, it is important to consider another possible reason for electronic correlations arising from 3d orbitals in the atoms V that were not taken into account. Therefore, to achieve a comprehensive understanding, it is necessary to investigate the effect of electronic correlations, particularly in the formation of CDW order in  $ScV_6Sn_6.$ 

In this work, we carried out a systematic study on  $\rm ScV_6Sn_6$  by using density functional theory plus dynamical mean field theory (DFT + DMFT) method. The calculated dependence of static spin susceptibility on temperature indicates the absence of local moment on atom V and we attribute it to the strong hybridization between V 3d orbital and Sn 5p, Sc 3d orbitals. The calculated mass enhancement  $m^*/m_{DFT}$  is about 1.3 and insensitive to the variation of temperature, similar to that in  $AV_3Sb_5$  ( $A = K$ , Rb, Cs) [\[41,](#page-6-5) [42\]](#page-6-6). Meanwhile, there are some weak variations in band structure near the Fermi level  $(E_F)$  brought by electronic correlations. Hence,  $\rm ScV_6Sn_6$  is recognized as a weakly correlated metal. Furthermore, the Fermi surface is slightly affected by electronic correlations, validating the conclusion that FSN is not the driving force of CDW order in  $ScV_6Sn_6$  drawn by previous DFT calculations [\[38–](#page-6-2)[40\]](#page-6-4). We also compared the mass enhancements in  $ScV_6Sn_6$  and  $\gamma V_6Sn_6$  where no CDW order was observed. The comparable values suggest that electronic correlations are not crucial for determining the CDW order in  $ScV_6Sn_6$ .

### II. METHODS

We conducted fully charge self-consistent DFT + DMFT calculations by using the eDMFT code [\[43\]](#page-6-7) developed by Haule et al. The DFT part employed the linearized augmented plane-wave method as implemented in the WIEN2K package [\[44\]](#page-6-8). The Perdew-Burke-Ernzerhof generalized gradient approximation [\[45\]](#page-6-9) was utilized for the exchange-correlation functional. Brillouin-zone integrations were performed on a  $21 \times 21 \times 10$  mesh. The atomic sphere radii  $(R_{\text{MT}})$  for Sc, V, and Sn were all set to 2.50 Bohr, and the plane-wave cutoff  $(K_{\text{max}})$ was determined by  $R_{\text{MT}} \times K_{\text{max}} = 7.0$ . In the DMFT calculations, the projector to the local Green's function was fixed to the solution of the Dirac equation at the DFT level. Hybridization functions were considered within an energy window of 20 eV centered around  $E_F$ . We deal with the double counting by the formula of  $U(n-1/2) - J_H(n-1)/2$ , where  $n = 3.0$  represents the nominal occupation of V 3d electrons,  $U=5.0$  eV represents the Coulomb interaction parameter, and  $J_H=0.7$ eV represents the Hund's exchange parameter. The adopted values are consistent with previous calculations in V-based correlated compounds, including  $AV_3Sb_5$  (A  $= K$ , Rb, Cs) [\[41,](#page-6-5) [42\]](#page-6-6)and vanadium oxides including SrVO<sub>3</sub> [\[46,](#page-6-10) [47\]](#page-6-11), CaVO<sub>3</sub> [\[48\]](#page-6-12), VO<sub>2</sub>[\[49\]](#page-6-13) and V<sub>2</sub>O<sub>3</sub>[\[50,](#page-6-14) [51\]](#page-6-15). For the DMFT impurity solver, we adopted the densitydensity form of Coulomb repulsion, which significantly accelerated the calculations. All five V 3d orbitals were treated as correlated. The DMFT quantum impurity problem was solved using the continuous-time quantum Monte Carlo (CTQMC) method [\[52,](#page-6-16) [53\]](#page-6-17) at a temperature of  $T = 116$  K. Upon achieving the desired accuracy, analytical continuation was performed using the maximum entropy method [\[43\]](#page-6-7) to obtain the self-energy on the real axis and subsequently calculate the electronic structure. We have confirmed that the incorporation of spin-orbit coupling has negligible influence on the conclusion. We therefore only present the results without considering spin-orbit coupling in the following.

# III. RESULTS AND DISCUSSION

## A. Crystal structure

Figure  $1(a)$  is the three-dimensional crystal structure of  $ScV_6Sn_6$ , showing a typical HfFe<sub>6</sub>Ge<sub>6</sub>-type compound. Within one unit cell of  $ScV_6Sn_6$ , there are two Kagome layers formed by V and Sn2 atoms, one honeycomb layer formed by Sn3 atoms and one triangular layer formed by Sc and Sn1 atoms, see Fig. 1(b). Within each Kagome layer, Sn2 atoms are slightly off the plane formed by V atoms. The lattice constants and internal coordinates used in our calculations are optimized by the Vienna Ab initio Simulation Package (VASP) [\[54\]](#page-6-18), until the atomic forces become less than  $10^{-3}$  eV/Å. The obtained lattice constants and internal atomic coordinates

are given in Table I, which are in good agreement with experimental reports [\[37\]](#page-6-1) and previous calculations [\[38\]](#page-6-2).

## B. Magnetism

To investigate the magnetism of  $ScV_6Sn_6$  and compare our calculational results with available experimental results, we present the temperature dependent static local spin susceptibility in Fig. 2(a). The static local spin susceptibility from CTQMC approach is defined as  $\chi = \int_0^\beta \langle S_z(\tau)S_z(0) \rangle d\tau$ , here  $\beta$  is the inverse temperature and  $\tau$  is the imaginary time. We take temperatures ranging from 58 to 900 K in the paramagnetic state in the calculations. In a magnetic system with local moments, this value would show a  $T$  dependence, typically following the Curie-Weiss law. However, as presented by the red dots in Fig.  $2(a)$ , the susceptibility exhibits a paramagnetism with an almost flat line independence of T. For good metals, this behavior indicates the the dominance of a Pauli paramagnetic response from itinerant electrons and the absence of local moments. This paramagnetic behavior resembles another V-based Kagome metal  $\rm{KV}_3Sb_5$  [\[42\]](#page-6-6), as shown by the blue line in Fig.  $2(a)$ . The DFT + DMFT results here is consistent with recent experimental measurement [\[37\]](#page-6-1).

To have more insight, we present the probability distribution for the different atomic configurations of  $V$  3d shell in Fig. 2(b). Within the  $DFT + DMFT$  scheme, each V impurity has 1024 3d states. The atomic histogram refers to the probability of finding a V impurity in each atomic state. We note that only those states oc-

FIG. 2. (a) Temperature dependent spin susceptibility obtained from CTQMC. The blue and red dots are  $ScV_6Sn_6$  and  $\rm{KV}_3Sb_5$ , respectively. The values of spin susceptibility of  $\rm{KV}_3Sb_5$  are from reference [\[42\]](#page-6-6). (b) Density functional theory (DFT) + dynamical mean field theory (DMFT) calculated atomic histogram of V 3d orbitals in  $\text{ScV}_6\text{Sn}_6$ , with  $U = 5$  eV and  $J_H =$ 0.7 eV. The states with occupation number exceeding five are not shown due to their negligible probabilities. (c) Imaginary part of the hybridization function on Matsubara frequencies at  $T = 116$  K.

cupied by  $N = 2, 3,$  and 4 electrons have considerable probabilities. Hence the states with larger orbital occupation number  $(N > 5)$  are not presented in Fig. 2(b). For the states with the same occupation number N, we arrange the states in descending order in accordance with their  $|S_z|$  values. Note that in the atomic limit, the configuration with occupancy  $n_d = 3$  should typically favor the high-spin state according to the Hund's rule. However, this is not the case in Fig. 2(b). Here, the close competition between different occupancy and spin states indicates strong charge and spin fluctuations in paramagnetic  $ScV_6Sn_6$ . This can be attributed to the strong hybridization between V 3d, Sn 5p, and Sc 3d orbitals. Figure 2(c) presents the imaginary parts of hybridization functions of the V 3d orbitals, which indicate a substantial delocalization of these orbitals (larger than 0.5 eV), especially for  $V-d_{z^2}$  orbital.

FIG. 3. (a) Imaginary part of the self-energy of V 3d shell on Matsubara frequencies at  $T = 116$  K. (b) The mass enhancement  $m^*/m_{DFT}$  in ScV<sub>6</sub>Sn<sub>6</sub> with different combinations of Coulomb interaction U and  $J_H$  (for each value of U,  $J_H$  is equal to  $0.14 \times U$ ).

### C. Mass enhancement

The effective mass enhancement is a straightforward and quantitative way to characterize the strength of electronic correlations. For weakly correlated systems, it is almost equal to 1 but much greater than 1 in strongly correlated systems, such as iron-based superconductors [\[55\]](#page-6-19) and heavy fermion materials [\[56,](#page-6-20) [57\]](#page-6-21). Within the  $DFT + DMFT$  method, we can obtain the effective mass enhancement  $m^*/m_{DFT}$ , which is equal to 1/Z, and Z is the quasiparticle weight  $Z = 1/(1 - \frac{\partial Im \Sigma(i\omega_n)}{\partial \omega_n})$  $\frac{i \Sigma(i \omega_n)}{\partial \omega_n} |_{\omega_n \to 0}),$ according to the calculated self-energy on Matsubara frequencies.

Figure 3(a) presents the imaginary parts of self-energy for all five V 3d orbitals at the temperature of 116 K in the paramagnetic state. In practice, we obtain  $m^*/m_{DFT}$  for each V 3d orbital by average the values computed by origin and the lowest Matsubara point and the lowest two Matsubara points. Figure 3(b) displays the computed mass enhancement  $m^*/m_{DFT}$  in  $ScV_6Sn_6$ with different values of Coulomb interaction  $U$  ranging from 3 to 7 eV and Hund interaction  $J_H = 0.14 \times U$ . For a typical U of 5.0 eV and  $J_H$  of 0.7 eV that is commonly used for other V-based compounds [\[41,](#page-6-5) [42,](#page-6-6) [46–](#page-6-10)[51\]](#page-6-15), our computed values of  $m^*/m_{DFT}$  in ScV<sub>6</sub>Sn<sub>6</sub> at 116 K are 1.406, 1.266, 1.345, 1.265, and 1.369 for V- $d_{z^2}$ , V- $d_{x^2-y^2}$ ,  $V-d_{xz}$ ,  $V-d_{yz}$ , and  $V-d_{xy}$  orbitals, respectively. These values are significantly smaller than the typical values in strongly correlated systems, suggesting the weak correlations in this compound. As shown in Figure 3(b), the  $V-d_{z^2}$  orbital emerges as the most responsive to changes in the interaction parameters. However, despite setting the value of U to 7 eV, the mass enhancement of  $V-d_{z^2}$ orbital only reaches a maximum value of 1.850. Furthermore, it has been confirmed that the computed value of  $m^*/m_{DFT}$  shows a small variation with temperature. For instance, the calculated  $m^*/m_{DFT}$  of V- $d_{z^2}$  is 1.421 at 58 K and 1.400 at 232 K.

### D. Correlated electronic structure

To investigate the effect of electronic correlations on electronic structure of  $\rm ScV_6Sn_6$ , we firstly plot the energy dispersion and density of states (DOS) calculated by DFT in Fig.  $4(a)$ . There is a large peak in DOS around 0.3 eV above  $E_F$  with a V 3d character, which could be attributed to the flat band alone the  $\Gamma$ -M-K- $\Gamma$  path, a typical feature present by Kagome lattice. From the band structure, we observe that this flat band is mainly contributed by  $V-d_{z^2}$  orbital. Another two characteristics of Kagome lattice can also be seen, including linear band crossings at K and saddle points at M just below  $E_F$ , in agreement with previous studies [\[38,](#page-6-2) [40\]](#page-6-4).

As a comparison, we plot the momentum-resolved spectral functions and momentum-integrated spectral functions obtained by the  $DFT + DMFT$  method in Fig. 4(b). The most obvious feature of the momentumresolved spectral functions is the incoherence away from  $E_F$ , indicating a somewhat short quasiparticle lifetime away from  $E_F$ . However, the spectra near  $E_F$  exhibit good coherence, and the bandwidths are weakly renormalized when compared with the DFT band structure represented by the gold dashed lines. Overall, our calculations show that  $ScV_6Sn_6$  could be a weakly correlated metal. It is necessary to emphasize that while local correlation is adequately considered in the DFT + DMFT calculation, the influence of long-range correlation on the electronic structure of  $ScV_6Sn_6$  has been omitted. Therefore, it is imperative to investigate the impact of longrange correlation in future research. For instance, employing the  $DFT + HSE06$  method would provide valuable insights into this aspect.

Figure 5(a) shows the DFT Fermi surface in the first Brillouin zone. In contrast to  $AV_3Sb_5$  ( $A = K$ , Rb, Cs) [\[41,](#page-6-5) [42\]](#page-6-6), one prominent distinguishing feature is the three-dimensionality with respect to  $k_z$ . Comparing the Fermi surfaces from DFT and DFT + DMFT, one can see that the most obvious variation brought by electronic correlations are the increment of the size of the pocket centered at the middle of  $L - M$ , see Fig. 5(b). This variation could be due to the lift of the bands forming a crossing near  $E_F$  alone  $L-M$ . However, apart from this discrepancy, the Fermi surface obtained by the  $DFT +$ DMFT method is quite similar to that from DFT.

#### E. Charge density wave

FSN is one of the underlying mechanisms of the lattice instability. The idea is that if Fermi surface contours coincide when shifted along the observed CDW wave vector, then the CDW is considered to be nesting derived. The imaginary part of the bare charge susceptibility under zero-frequency limit, namely FSN function, describing the degree of the FSN with a certain nesting vector q is defined as  $\lim_{\omega \to 0} \chi''_0(q,\omega)/\omega =$ 

FIG. 4. (a) Orbital projected DFT energy dispersion and density of states, with V- $d_{z^2}$ , V- $d_{x^2-y^2}$ , V- $d_{xy}$ , V- $d_{xz}$  and V $d_{yz}$  orbitals labeled by blue, cyan, green, yellow and red lines, respectively. (b) Momentum-resolved spectral functions and momentum-integrated spectral functions from DFT + DMFT method at  $T = 116$  K. The DFT band structure given by gold dashed lines is attached for comparison.

 $\sum$  $_{nn^{\prime},\boldsymbol{k}}$  $\delta(\epsilon_{n,\mathbf{k}}-\epsilon_0)\delta(\epsilon_{n',\mathbf{k+q}}-\epsilon_0)$  where  $\delta$  is the Dirac-delta

function,  $\epsilon_{n,k}$  is the eigenvalue of nth band at k point, and  $\epsilon_0$  is the Fermi energy.

FSN was revealed as a strong candidate for driving CDW formation in rare-earth tritellurides, including  $GdTe<sub>3</sub>$  and  $LuTe<sub>3</sub>$  [\[58\]](#page-6-22). However, according to previous DFT calculations, FSN was excluded as the primary driving force behind the CDW order in  $ScV_6Sn_6$  [\[38,](#page-6-2) [39\]](#page-6-3). To take electronic correlations into account, we plot the DFT + DMFT calculated FSN function on the  $q_z = 0$ , 1/3, and 1/2 planes, respectively, in Fig. 6. Here a dense k-mesh of  $100 \times 100 \times 51$  and a small Gaussian broadening factor of 0.001 eV in Dirac-delta functions are used to display

FIG. 6. The DFT  $+$  DMFT calculated imaginary parts of the electron susceptibility  $\chi(q)$ , namely Fermi surface nesting function, on (a)  $q_z = 0$ , (b)  $q_z = 1/3$  and (c)  $q_z = 1/2$  planes. White hexagons in all panels represent the in-plane Brillouin zone, corresponding high-symmetry points on each plane are labeled.

the relative strength of the FSN function at different  $q$ points. In contrast to  $AV_3Sb_5$   $(A = K, Rb, Cs)$  with weak  $q_z$  dependence [\[41,](#page-6-5) [42\]](#page-6-6), the maximum of the FSN function of  $ScV_6Sn_6$  undergoes a transition. Specifically, as  $q_z$  varies from 0 to  $1/3$  to  $1/2$ , the maximum shifts from M (Fig. 6(a)) to alone  $\Gamma - M$  and near  $\Gamma$  (Fig.  $6(b)$ ), and ultimately settles at the middle of  $L-H$  (Fig.  $6(c)$ ). Single crystal x-ray diffraction determined CDW wave vector in  $\text{ScV}_6\text{Sn}_6$  is  $q_{CDW} = (1/3, 1/3, 1/3)[37]$  $q_{CDW} = (1/3, 1/3, 1/3)[37]$ . If the CDW is indeed caused by FSN, the maximum should be located at the  $\overline{K}$  point in Fig. 6(b), but this is not the case. We therefore conclude that FSN is unlikely to be the direct cause of the CDW instability in  $ScV_6Sn_6$ even when electronic correlations are considered.

To further illustrate the dependence of CDW order on electronic correlations, we compare the correlation strength of quasiparticles in  $ScV_6Sn_6$  and non-CDW compound  $\rm{YV_6Sn_6}$ . Owing to the larger radius of atom Y, lattice constant a is larger in  $\rm{YV_6Sn_6}$  than  $\rm{ScV_6Sn_6}$ [\[59\]](#page-6-23). However, as listed in Table II, the calculated orbital occupation numbers and mass enhancements in these two compounds exhibit a striking similarity. For instance, the mass enhancement of the most correlated orbital  $V-d_{z^2}$  is 1.406 in  $ScV_6Sn_6$  and 1.423 in  $\rm{YV_6Sn_6}$ . We propose that electronic correlations are not crucial for the formation of CDW order in  $ScV_6Sn_6$ .

Recently, Cao et al. [\[40\]](#page-6-4) observed a remarkably large

q-dependent electron-phonon coupling, which has been proposed as the underlying mechanism responsible for the CDW order in  $\rm ScV_6Sn_6$ . Given the weak electronic correlation strength observed in our DFT + DMFT calculations, the electronic correlations will not significantly affect this conclusion. Therefore, we support the notion that the  $q$ -dependent electron-phonon coupling is a strong candidate for driving the CDW order in  $ScV_6Sn_6$ .

#### IV. CONCLUSIONS

In summary, based on DFT + DMFT calculations, we studied the magnetism and electronic correlation effects in  $ScV_6Sn_6$ . The spin susceptibility is nearly independent of temperature, indicating the absence of local moment on atom V and consistent with experimental reports. By analyzing the computed atomic histogram and hybridization functions, we attribute the absence of local moment to the strong hybridization between V  $3d$ , Sn  $5p$ , and Sc 3d orbitals. The mass enhancement is about 1.3 and the bandwidths near  $E_F$  are weakly renormalized by electronic correlations, indicating the weak electronic correlation strength in  $ScV_6Sn_6$ . The calculated FSN function with the inclusion of electronic correlations shows no maximum at experimentally determined  $q_{CDW}$ , suggesting that FSN is not the driving force of CDW order in  $ScV_6Sn_6$ . Furthermore, the comparable values of quasiparticle mass enhancements in  $ScV_6Sn_6$  and non-CDW  $\rm{YV}_6Sn_6$  suggest that the electronic correlations play a non-crucial role in the formation of the CDW order in  $ScV_6Sn_6$ .
