# Toward an Insider Threat Education Platform: A Theoretical Literature Review

Haywood Gelman <sup>1</sup>, John D. Hastings <sup>1</sup> David Kenley <sup>1</sup>, and Eleanor Loiacono <sup>1</sup>

Abstract—Insider threats (InTs) within organizations are small in number but have a disproportionate ability to damage systems, information, and infrastructure. Existing InT research studies the problem from psychological, technical, and educational perspectives. Proposed theories include research on psychological indicators, machine learning, user behavioral log analysis, and educational methods to teach employees recognition and mitigation techniques. Because InTs are a human problem, training methods that address InT detection from a behavioral perspective are critical. While numerous technological and psychological theories exist on detection, prevention, and mitigation, few training methods prioritize psychological indicators. This literature review studied peer-reviewed, InT research organized by subtopic and extracted critical theories from psychological, technical, and educational disciplines. In doing so, this is the first study to comprehensively organize research across all three approaches in a manner which properly informs the development of an InT education platform.

Index Terms—Insider Threats (InTs), Psychological Indicators, Behavioral Analytics, InT Detection and Prevention, InT Training

## I. INTRODUCTION

Insider threats (InTs) are among the most impactful risks facing organizations today. Insiders present a great threat to organizations due to their sanctioned access to systems, information, and infrastructure and the damage that can occur should they decide to act against the interests of an employer [1]. Recent statistics highlight the severity of the issue: in 2023, InTs were responsible for approximately 20% of attacks on organizations across a range of attack vectors, while 74% of attacks involved human interaction [2]. This suggests that insider threats are not only technical but also deeply human problems, influenced by a range of psychological, behavioral, and organizational factors.

The increasing prevalence of InT incidents, rising from 68% in 2021 to 74% in 2023 [3], underscores the urgent need for organizations to implement robust detection and mitigation strategies. These strategies must encompass both technological solutions and human-centered approaches to detect and respond to potential threats effectively. However, while significant advances have been made in technological

detection systems, such as machine learning and user behavior analytics, the psychological perspective of insider threats remains underexplored [4]. This study aims to address this gap by classifying theories related to developing the necessary training methods to effectively detect InTs with a particular emphasis on the psychological perspectives. In doing so, this is the first study to comprehensively organize research related to psychological, technological, and educational approaches.

# II. METHODOLOGY

This study conducted a theoretical literature review that assessed psychological, technical, and educational perspectives on InT theories and subtopics. [5], [6] guided the approach to safeguard validity, minimize theoretical misinterpretation through triangulation, and to avoid selection bias through applicable search term construction. Content for theory extraction was sourced from searches conducted in peer-reviewed journals and conference papers using IEEE Xplore, ACM, Web of Science, and Google Scholar. Keywords included "psych", "educ", ontology", "framework", "model", "persona", "PMT", "trust", "machine", "big data", "behav", "analytic", "user analytic" combined with "inside" and "insider threat". The progressive nature of the field negated the need for a publication date range, which enabled inclusion of three seminal psychological texts [7]–[9]. Theoretical extraction by application yielded common subtopics across psychology, technology, and education domains for analysis. The following sections detail the findings organized by psychological, technological, and educational approaches.

# **III. PSYCHOLOGICAL INT THEORIES**

Psychological theories for InTs address characteristics, motivations, behaviors (CMB) [10], and dark traits [11] used to identify organizational threats. [12] distinguished insiders from InTs based on an employee's sanctioned access to systems, information, and infrastructure, their legitimate physical or virtual presence within the organization's management boundaries, and InT potential to cause organizational harm. [13] set precedent for [12] in stating the juxtaposition of InT attacks are in proximity to adverse employment incidents and work dissolution.

## A. InT Ontology

InT ontology described an InT lexicon to define crucial aspects of InT terminology. Unintentional InT was similarly determined by [14] and [15] to include carelessness, lack of training, and susceptibility to social engineering. [16], citing

<sup>&</sup>lt;sup>†</sup>The Beacom College of Computer & Cyber Sciences, Dakota State University, Madison, SD, USA. Email: haywood.gelman@trojans.dsu.edu

<sup>&</sup>lt;sup>‡</sup>The Beacom College of Computer & Cyber Sciences, Dakota State University, Madison, SD, USA. Email: john.hastings@dsu.edu

[4], added that unintentional InT actions could be caused through "action or inaction without malicious intent."

Intentional threats are distinguished from unintentional threats by their mens rea [14]. [17], citing [9] and [18], described intentional InT by the Five Factor Model and dark traits. The Five Factor Model included "extraversion, agreeableness, conscientiousness, neuroticism, and openness to experience" [9].

Dark traits were described by [18] as sinister aspects of personality considered to be below a level required for diagnosis but can be observed symptomatically [18]. Dark traits include narcissism (self-interest), Machiavellianism (scheming), and psychopathy (lack of self-control) [18], [19]. [19] noted that due to the broad range of identification in the Five Factor Model, the model had not found wide acceptance in InT research circles, validated by [11]. [11] also noted the inclusion of empathy and sense of entitlement to InT characteristics outside of dark traits [11].

[20] introduced the concept of InT triggered by opportunity to commit an InT action. [20] also cited [21], stating that "both motivation and opportunity play a role in crime; however, opportunity may be the 'trigger' to committing a crime." [20]. [22] also described similarities to Cressey's Fraud Triangle [8]: behavioral characteristics that enable an InT to self-incentivize to commit an act, possessing the foresight to perceive an opening, and the ability to justify the behavior.

# B. Frameworks and Models

InT frameworks and models are methods for creating predictability in InT detections. [23] proposed the implementation of a detection model based on a combination of CMB of attackers, simulated attacks, and case studies. Research focused on building a library of case studies, dissecting them for their characteristic value, and extracting predictability features.

Where [23] concentrated on malicious and accidental InT attacks, [20] addressed threats from an opportunity landscape perspective. Citing [21], [20] noted the presence of incentive and prospectus in the commission of a crime, connecting these factors to InT who are catalysts to commit an InT act but wait for the prospect to surface. [24] modified this theory, granting heavier weight to prospectus over incentive. Padayachee's position was contradicted by [25], stating three well-known factors of crime commission – means, motive, and opportunity – where the reduction of one reduced the likelihood and/or impact of an InT attack.

Rather than addressing the criminological perspective of opportunity-based threats, [26] proposed a framework for InT detection based on behavioral indicators. Technology and nontechnology based indicators were compiled from case studies to create an ontology of InT to inform the model. The research used the risk management model OCTAVE to validate indicators, although the model developers caution [27] that it is not specified for InT risk management.

In contrast to [26] and [20], [24], [28] proposed a conventional layered defense model through technological and user entity behavioral anomaly detection.

# C. Personas

In addition to opportunity-based threats, unintentional and intentional threats address the most commonly seen InTs in organizations. [29] [11] CERT Insider Threat Team described CMB of unintentional InTs to include carelessness, lacking mindfulness of surroundings, and reduced awareness of consequences of unconscious compromise. [15] and [16] agreed with [29], but also determined that unintentional InTs can cause damage by either active participation or inactivity.

[30] and [14] described the Cybersecurity Questionnaire (CSEC) as an instrument to determine the level of risk an unintentional InT poses to an organization based on cyber habits. Contrary to [15], [14] noted the characteristic of communal involvement, where such activity could be viewed negatively in relation to social engineering.

[31] expanded on social engineering, explaining that the susceptibility of individuals to the act was related to six ideologies of influence: authority, commitment, reciprocity, liking, social proof, and scarcity.

Discussing intentional InTs, [32] described the decision to commit a malicious act as predicated on a perceived injustice, progressing through several stages before completion and flight. [11] identified the traits necessary to commit an intentional InT act as dark traits: non-criminal characteristics that enable an individual to bypass morality, willfully cause damage, and consciously plan an escape.

Dark traits were extended by [19] to include a complex set of associated emotions and behaviors, applicable to both intentional and unintentional InTs. [22] assented on emotional complexity, adding cognitive nullification as a negative counterbalance to committing an InT crime.

Protection Motivation Theory (PMT) applied to intentional InTs exhibited unique properties. According to [33], PMT psychological behavior applied to those in a position to cause harm chose to protect individuals and organizations instead. This unique property demonstrates an opposing view to [11] and [32]. [34] and [35] concurred.

# D. Prevention

Prevention strategies seek to identify methods to mitigate InT attacks. [36] organized InT defense into three categories, "detection approaches, detection & prevention approaches, or prevention approaches."

[1] identified a detection approach based on psychological antecedents. Their method assessed emotional state, complaints outside the workplace, distraction, and other characteristics that were indicative of an impending InT attack.

[37] proposed a prevention strategy based on stress from organizational peer relationships and consequences enforced by the organization for violations. The research concluded that InT behaviors can be manipulated by internal and external factors.

[38] agreed with [37] on influencing factors, adding psychological triggers as a preceding act. [39] studied the preventive impact of distress petitions on the protection response of organizational IT communities, finding a positive correlation.

[40] proposed a detection and prevention approach by identifying numerous work and personal indicators of stress and compromise. Although [40]'s indicators were accurately identified, research minimally described noted traits as psy-chologically impacting, departing from the focus of the paper. [41] appraised performance management, control failure, behavioral moderation, authentication policy, and preemptive detection.

#### **IV. TECHNOLOGICAL THEORIES**

Technological theories are models that utilize technology to aid in InT discovery and mitigation. Subtopics include datadriven and machine-learning, trusted user approaches, and user behavior analytics.

#### A. Data-Driven & Machine Learning Theories

[42] proposed a system-level framework that detected and prevented unauthorized database changes through an automated security-defense mechanism based on administrative policy. [43] presented an approach directly applicable to detection through behavioral analysis and game theory simulation. [43] implemented machine learning for data analysis but used game simulation to collect data for the model.

[44] also proposed a game theory approach using a World of Warcraft dataset to preemptively model InT behavior through a machine learning approach applied to psychological profiling and graph learning. Using structural anomaly detection (analysis of normal computer-use behavior) and psychological profiling (assessment of anomalous behavior arising out of computer use tracking), the model effectively predicted InT behavior when combining indicators.

[45] proposed creation of a neural network, DANTE, for detecting InT anomalous behavior in system logs. Although DANTE showed a 93% success rate detecting InTs, the dataset was simulated [46], and it was only successful in identifying known attacks [45].

[47] employed a system dynamics model to assess vulnerabilities in enterprise environments. Through the researchers application of their dynamic trigger hypothesis (assessment of inferential indicators that create an environment in which InTs can thrive) the model was simulated to stimulate the surfacing of psychological precursors to vulnerabilities. Research concluded that technology and behavioral modeling of InTs were only as effective as humans ability to interpret them.

[48] proposed the use of a machine learning simulation for their InT immersion study but with participant observational awareness and a requirement to act with fraudulent intent during the study. Simulation demonstrated a positive result for InT detection.

[49] concurred on the use of machine learning to overcome the non-real-time nature of IT vulnerability processing. [50] observed higher correlation for InT detection with unsupervised learning over supervised machine learning models.

# B. Trust Theories

Trust theories involve human-dependent access levels to systems, information, and infrastructure relative to human reliability [51]. Organizational trust levels increase as reliability increases, while simultaneously demonstrating an exponential increase in the relationship between trust levels and damage caused by trusted insiders [51].

[52] proposed use of the SI\* modeling language to address InT behavior using an asset, role, and behavior-based framework to establish simulated trust levels between objects in a patient observation setting. The model proposed a design to enable IT staff to model user behavior on systems and permissions to preemptively determine individuals as malicious insiders.

[53] described a taxonomy for exploiting trusted social networking applications and the insertion of social networking malware (socioware) to steal personal information. In contrast to [52] and [53], [54] proposed an unsupervised machine learning model to mine system logs for untrusted activities, noting [55] observed higher correlation with unsupervised learning.

[25] studied a trust-matrix framework based on characteristics derived from CERT's Common Sense Guide to Mitigating Insider Threats dataset [46]. The model distilled trust aspects, character and competence, into behaviors associated with intent, integrity, capability, and results across a behavioral lifespan. The study instrument demonstrated positive correlation for the model.

[56] assessed trustworthiness through the perception of humans-as-sensors, trained to observe anomalous behavior, akin to a firewall. The research determined a positive correlation between trained human observers and detection of InTs.

[57] discovered a positive correlation between distributed intrusion detection appliances and InT detection when implementing multi-level trust across collective detectors. In their qualitative study and in contrast to technological models, [58] addressed the replacement of the trusted computing model to reduce the risk of InTs through participant interviews.

#### C. User Behavioral Analytics Theories

User behavioral analytics theories model and analyze human behavior through unsupervised machine learning, user roles, behavioral profiling & historical analysis, and user intent. [59]'s literature review described industry approaches to user entity behavioral analysis (UEBA) tools that use supervised and unsupervised machine learning to mine logging facilities for evidence of InT behavior, but did not provide a novel approach to solve the problem.

Similar to [25] and [45], [60] used CERT's Common Sense Guide to Mitigating Insider Threats dataset [46] to model InT behavior. Unlike [25]'s assessment of trust behaviors and [45]'s known-behavior limitation, [60] trained a deep-learning model on historical user behavioral sequencing to achieve a 99.15% detection success rate.

[48] approach to environmental simulation enlisted participants with awareness of the experiment but not the scenario to encourage expected InT behaviors. Participants were required to commit actions designed to trigger machine learning recognition.

[61] designed a model based on a human-driven augmented decision making framework. In their model, data extraction methods used by [60], in conjunction with the CERT InT dataset [46], and an unsupervised deep-learning model similar to [54], and [50], produced improved results over existing test methods at a mean of 84.12%.

#### V. EDUCATIONAL FRAMEWORKS AND MODELS

Educational frameworks and models refer to theories applied to teaching security education, training, and awareness (SETA) concepts to an array of participant profiles. To assess educational frameworks and models for InTs, it is necessary to include generalized SETA so a complete set of theories can be drawn. [62] and [63] reformed national cybersecurity protection initiatives specific to InTs. Also, [64] provides a strong foundation for generalizable SETA that can be modified for InT education purposes. The NICE Framework [65] presents a competency and role-based training solution founded on task, knowledge, and skill objectives. In addition, CDSE Insider Threat training [66], the MERIT program [13] and the CERT Guide to Insider Threats [4] are crucial examples of effective InT training. These generalized and InT-specific education initiatives embody critical perspectives that directly address this research's focus. The following section enumerates important educational frameworks and models applicable to psychologyfocused InT training.

[67] applied Bloom's Taxonomy of cognition [7] to cyber education to assess learning levels and outcomes mapped to NICE Framework objectives. [68] applied expectancy theory to SETA to influence "security-related behavior". Expectancy theory involves inducing an outcome by influencing the factors that create it, similar to PMT [33], [35] but with a control. [69] concurred on PMT, while including Theory of Reasoned Action and Behaviorism Theory. [68] discovered positive correlation between SETA and insider security behaviors.

[13] presented a SETA guide on InTs specific to sabotage in the workplace. The model utilized psychological aspects of InTs, along with CMB, in a design to create predictive and preventive behaviors in an organization. [70] employed a case study approach to train nuclear power system educators on how to teach their nuclear system operator classes in the United Kingdom.

When teaching in a heterogeneous environment, it is important to employ training methods that accommodate different knowledge absorption techniques, according to the Felder-Silverman learning style model (FSLSM) [71]. FSLSM can also be seen in the interactive, adventure-driven video game CyberCIEGE [72]. The game was used to successfully teach SETA to Navy students through scenarios and problem solving exercises [72]. [73] added hands-on lab exercises to further improve SETA's cognitive impact.

# VI. SUMMARY OF INT THEORIES

This study extracted, compared, and contrasted psychological, technical, and educational InT theories for future synthesis with an InT psychological-focused training initiatives. Supporting psychological theories include CMB, dark traits and cognitive nullification, organizational harm, adverse employment incidents, unintentional InTs and social engineering, intentional InTs, opportunity-based InTs, PMT, prevention categories, antecedents, peer relationships and stress, distress petitions, and preemptive action.

Technological theories include InT behavior modeling, system log behavioral analysis, observational awareness, unsupervised machine learning, trusted insiders, trusted behaviors, historical user behavior deep-learning, and trained human behaviors.

Educational theories include generalized and InT SETA training, Bloom's taxonomy of cognition, security-related behavior, case study analysis, adjusting SETA methods to learners knowledge absorption methods, and hands-on lab exercises.

# VII. CONCLUSION

A large body of knowledge exists on the psychology of InTs. Research addressed existing studies, frameworks, ontologies, and theories that propose identification of InTs from characteristics, motivations, behaviors, and dark traits of InT personas. An equally large body of knowledge exists on technological means of detecting InTs through behavioral and observational analysis, machine learning, and trusted behaviors. Organizations rely heavily upon technology to spot indicators of InTs, most notably when addressing an entity that can be inherently unpredictable. Numerous guidelines exist on how organizations should train employees on InTs, but gaps in training methods possess an imbalance between psychological and technical detection and mitigation methods. Future research will create an awareness training platform for organizations on InTs based on psychology first and technology second. The conceptual framework will draw upon determiners of InT activity from psychological, technological, and educational theories extracted in this paper and implemented as part of a comprehensive InT training platform.
