An anisotropic flat band fermion system with a novel dispersion that is linear along one direction and cubic along another is proposed in Phys. Rev. X. 13, 021012 (2023). We study the effects of Coulomb interaction in this fermion system by renormalization group theory and Dyson-Schwinger gap equation. We perform renormalizaton group analysis and find that fermion velocity is always restored along the direction that the fermions take cubic dispersion originally. Accordingly, the system takes the similar behaviors to the two-dimensional Dirac fermion system with Coulomb interaction in the low energy regime. Based on Dyson-Schwinger gap equation method, we find that an excitonic gap is generated if the Coulomb strength is large enough, and the system becomes a novel excitonic Chern insulator with quantized anomalous Hall conductivity. Observable quantities of this system in free case, under weak and strong enough Coulomb interaction are all analyzed.

Introduction. Dirac materials attract extensive studies in the past two decades [\[1](#page-4-2)[–9](#page-4-3)]. Graphene is a typical two-dimensional (2D) Dirac semimetal [\[1](#page-4-2)[–4\]](#page-4-4). The surface state of three-dimensional (3D) topological insulator is another typical 2D Dirac semimetal [\[3](#page-4-5)[–6](#page-4-6)]. For 2D Dirac semimetal, the Fermi surface is discrete point and density of states takes the behavior $\rho(\omega) \propto \omega$, which vanishes at the Fermi level, i.e. $\rho(0) = 0$. Accordingly, the theoretical studies showed that short-range four-fermion interactions are irrelevant if the interactions are weak, but could drive various quantum phase transitions if the interactions are strong enough [\[2](#page-4-7), [10,](#page-4-8) [11\]](#page-4-9). Whereas, the Coulomb interaction is long-ranged due to the vanishing of density of states. It was shown that Dirac fermion velocity in 2D Dirac semimetal increases logarithmically with lowering of momenta under long-range Coulomb interaction [\[2,](#page-4-7) [12](#page-4-10)[–14\]](#page-4-11). The singular renormalization of fermion velocity has been observed in graphene through many different experiments [\[15](#page-4-12)[–17](#page-4-13)]. There has been also experimental evidence for the singular renormalization of fermion velocity for the surface state of 3D topological insulator [\[18](#page-4-14)].

Turning some parameter properly, the fermion velocity of Dirac materials becomes to vanish and the band becomes flat [\[19](#page-4-15)[–30\]](#page-5-0). For twisted bilayer graphene, the Dirac fermion velocity vanishes if the twist angle between graphene layers is tuned to magic angles [\[19](#page-4-15), [20\]](#page-5-1). For the surface state of 3D topological insulator, it was shown that the Dirac fermion velocity vanishes if periodic potential is applied [\[21,](#page-5-2) [22\]](#page-5-3). Flat band also emerges in twisted multilayer graphene, twisted transition metal dichalcogenide, and other moire materials [\[23](#page-5-4)[–29\]](#page-5-5). For Bernal bilayer graphene and rhombohedral multilayer graphene, the band becomes flat and the energy dispersion of fermions takes the form $E \propto \pm k^N$, where N is number of layers [\[31](#page-5-6)[–34\]](#page-5-7). Accordingly, the density of states satisfies $\rho(\omega) \propto \omega^{\frac{2}{N}-1}$, which is obviously enhanced comparing to monolayer graphene. In proper conditions, higher-order van Hove point appears in the

flat band fermion system [\[35](#page-5-8)[–39\]](#page-5-9).

For a fermion system with flat band, the kinetic energy is suppressed, and thus correlation effects are usually much enhanced [\[23](#page-5-4)[–30](#page-5-0)]. Many novel strong correlated phenomena, including Mott insulator [\[40](#page-5-10)[–42](#page-5-11)], unconventional superconductivity [\[43](#page-5-12)[–54\]](#page-5-13), non-Fermi liquid behaviors [\[55,](#page-5-14) [56\]](#page-6-0), various quantum phase transitions [\[23](#page-5-4)[–30\]](#page-5-0), fractional quantum anomalous Hall effect [\[57](#page-6-1)– [59](#page-6-2)] etc., are found in the flat band fermion systems.

Recently, Sheffer et al. found that an anisotropic flat band emerges in the surface state of 3D topological insulator if C_4 broken periodic potential is imposed properly [\[60\]](#page-6-3). They showed that the Dirac fermion velocity holds along one direction and vanishes along another direction. Accordingly, the fermion dispersion is linear along one direction and cubic along the another. They raised a very interesting question about the behaviors of this system if interactions are considered, which yet to be resolved.

In this Letter, we study the influence of Coulomb interaction on this anisotropic flat band fermion system with a linear-cubic fermion dispersion. This fermion system can be also regarded as an anisotropic semimetal state. In this system, the density of states takes the form $\rho(\omega) \propto \omega^{\frac{1}{3}}$ which vanishes that the Fermi level. Thus, the Coulomb interaction in this system is long-ranged, which could induce strong-correlated phenomena.

Influence of long-range Coulomb interaction on various semimetal state attracted broad interest [\[62](#page-6-4)[–82\]](#page-6-5). These studies manifest that the results subtly depend on the dispersion of fermions and dimension of the system, and thus need careful analysis. In the following, we study the influence of long-range Coulomb interaction on this anisotropic flat band fermion system by renormalization group (RG) theory [\[61\]](#page-6-6) and self-consistent Dyson-Schwinger gap equation. We reveal the behaviors of the system not only in presence of weak Coulomb interaction but also with strong Coulomb interaction.

The model. The action of free fermions can be writ-

FIG. 1: Fermion dispersion of anisotropic band with linearcubic fermion (a) in free case, (b) with weak Coulomb interaction becomes, and (c) with strong enough Coulomb interaction.

ten as

$$
S_{\psi} = \int \frac{d\omega}{2\pi} \frac{d^2 \mathbf{k}}{(2\pi)^2} \psi^{\dagger} \left(-i\omega + \mathcal{H}_f(\mathbf{k}) \right) \psi, \tag{1}
$$

where the Hamiltonian for the the fermions is

$$
\mathcal{H}_f(\mathbf{k}) = v_x k_x \sigma_1 + d_y k_y^3 \sigma_2.
$$
 (2)

The field operator ψ is a two-component spinor. σ_i with $i = 1, 2, 3$ are the Pauli matrices. v_x and d_y are the model parameters. The fermion energy dispersion is given by

$$
E = \pm \sqrt{v_x^2 k_x^2 + d_y^2 k_y^6},\tag{3}
$$

which is linear along one direction, and cubic along another direction.

The Coulomb interaction between fermions takes the form

$$
H_C = \frac{1}{4\pi} \int d^2 \mathbf{x} d^2 \mathbf{x}' \rho(\mathbf{x}) \frac{e^2}{\epsilon |\mathbf{x} - \mathbf{x}'|} \rho(\mathbf{x}'),\tag{4}
$$

where $\rho(\mathbf{x}) = \psi^{\dagger}(\mathbf{x})\psi(\mathbf{x})$ is fermion density operator, e electric charge, and ϵ dielectric constant.

The free fermion propagator reads

$$
G_0(\omega, \mathbf{k}) = \frac{1}{-i\omega + v_x k_x \sigma_1 + d_y k_y^3 \sigma_2}.
$$
 (5)

The bare Coulomb interaction is written in the momentum space as

$$
V_0(\mathbf{q}) = \frac{2\pi e^2}{\epsilon |\mathbf{q}|} = \frac{2\pi \alpha v}{|\mathbf{q}|},\tag{6}
$$

where $\alpha = e^2/\epsilon v_x$ represents the effective interaction strength.

The polarization is defined as

$$
\Pi(\Omega, \mathbf{q}) = -\int \frac{d\omega}{2\pi} \int \frac{d^2 \mathbf{k}}{(2\pi)^2} \text{Tr} [G_0(\omega, \mathbf{k})
$$

$$
\times G_0 (\omega + \Omega, \mathbf{k} + \mathbf{q})]. \tag{7}
$$

Substituting the fermion propagator, we find the polarization can be approximately by [\[83\]](#page-6-7)

$$
\Pi(\Omega, q_x, q_y) = \frac{1}{v_x d_y^{\frac{1}{3}}} \left[\frac{c_1 v_x^2 q_x^2}{\left(\Omega^2 + v_x^2 q_x^2 + \frac{c_3^6}{c_2^6} d_y^2 q_y^6\right)^{\frac{5}{6}}} + \frac{c_3 d_y^{\frac{2}{3}} q_y^2}{\left(\Omega^2 + v_x^2 q_x^2 + \frac{c_3^6}{c_2^6} d_y^2 q_y^6\right)^{\frac{1}{6}}}\right], \quad (8)
$$

where

$$
c_1 = \frac{\Gamma(\frac{1}{6})}{24 \cdot 2^{\frac{1}{3}} \sqrt{\pi} \Gamma(\frac{2}{3})}, \qquad c_2 = \frac{17}{144},
$$

$$
c_3 = \frac{9 \Gamma(\frac{5}{6})}{32 \cdot 2^{\frac{2}{3}} \sqrt{\pi} \Gamma(\frac{4}{3})}.
$$
 (9)

Restoring of fermion velocity. In the following, we analyze the effects of Coulomb interaction through RG method [\[61\]](#page-6-6). Firstly, we calculate the fermion selfenergy neglecting the screen from polarization function. The fermion self-energy can be written as

$$
\Sigma(\omega, \mathbf{k}) = \int \frac{d\Omega}{2\pi} \int' \frac{d^2 \mathbf{q}}{(2\pi)^2} G_0 \left(\omega + \Omega, \mathbf{k} + \mathbf{q}\right) V_0(\Omega, \mathbf{q}) (10)
$$

where \int' represents that a momentum shell will be imposed properly. Substituting the propagator of fermion as shown in Eq. [\(5\)](#page-1-0), and expanding to leading terms of k_x and k_y , we obtain

$$
\Sigma(\omega, \mathbf{k}) = -i\omega\Sigma_0 + v_x k_x \sigma_1 \Sigma_1 + d_y k_y^3 \sigma_2 \Sigma_2 + k_y \sigma_2 \Sigma_L,
$$
\n(11)

where the expressions of Σ_0 , Σ_1 , Σ_2 , Σ_L can be found in the Supplementary Materials [\[83\]](#page-6-7). We notice that linear term of k_y is always generated dynamically. According, the fermion velocity along y axis is restored.

In order to consider this dynamically generated term in RG analysis, we employ the fermion propagator as following

$$
G_0^{new}(\omega, \mathbf{k}) = \frac{1}{-i\omega + v_x k_x \sigma_1 + v_y k_y \sigma_2 + d_y k_y^3 \sigma_2}.
$$
 (12)

The bare value of v_y is taken to be zero in the RG analysis. The fermion self-energy can be written as

$$
\Sigma(\omega, k) = \int \frac{d\Omega}{2\pi} \int' \frac{d^2 \mathbf{q}}{(2\pi)^2} G_0^{new} (\omega + \Omega, \mathbf{k} + \mathbf{q})
$$

× $V_0(\Omega, \mathbf{q}).$ (13)

Substituting the propagator of fermion as shown in Eq. [\(12\)](#page-1-1), and expanding to the leading terms of ω , k_x and k_y , we arrive

$$
\Sigma(\omega, \mathbf{k}) = v_x k_x \sigma_1 C_1 \ell + v_y k_y \sigma_2 C_2^a \ell + d_y k_y^3 \sigma_2 C_2^b \ell(14)
$$

FIG. 2: Flows of $v_x(\ell), v_y(\ell), v_y(\ell)/v_x(\ell)$ and $\alpha(\ell)$ with different initial values of Coulomb strength. (a)-(d) Bare propagator of Coulomb interaction is employed. (e)-(f) Dressed Coulomb interaction is used. Initial value $\beta_0 = 1$ is taken.

 C_1, C_2^a , and C_2^b are functions of the parameters α, β , and $_2,$ and \cup_2 γ , which are defined as $\alpha = \frac{e^2}{\epsilon v}$ $\frac{e^2}{\epsilon v_x}, \ \beta = \frac{d_y \Lambda^2}{v_x}$ $\frac{y}{v_x}, \delta = v_y/v_x.$ The expressions of C_1 , C_2^a , and C_2^b are shown in [\[83\]](#page-6-7). The RG scheme $-\infty < \Omega < +\infty$, $b\Lambda < |\mathbf{q}| < \Lambda$ has been utilized, where $b = e^{-\ell}$ with ℓ being the RG running parameter. We get the RG equation as following

$$
\frac{dv_x}{d\ell} = C_1 v_x,\tag{15}
$$

$$
\frac{dv_y}{d\ell} = C_2^a v_y,\tag{16}
$$

$$
\frac{d\alpha}{d\ell} = -C_1\alpha.
$$
 (17)

The RG flows of $v_x(\ell), v_y(\ell), v_y(\ell)/v_x(\ell)$, and $\alpha(\ell)$ are shown in Figs. [2\(](#page-2-0)a)[-2\(](#page-2-0)d). $v_x(\ell)$ increases nearly linearly with increasing of ℓ . $v_y(\ell)$ grows from zero and also increases nearly linearly with increasing of ℓ . These results indicate that the fermion velocities v_x and v_y acquire logarithmic-like dependence on momenta. The ratio of fermion velocities $v_y(\ell)/v_x(\ell)$ approaches to 1 slowly with increasing of ℓ . The result that $\alpha(\ell)$ flows to zero slowly in the low energy limit $\ell \to \infty$ represents that Coulomb interaction is marginally irrelevant in the low energy regime.

Subsequently, we calculate the self-energy of fermions considering screen of polarization. In order to consider the original fermion dispersion and the influence of restoring of fermion velocity v_y . We employ the dressed Coulomb interaction as following

$$
V^{\star}(\Omega, \mathbf{q}) = \frac{1}{V_0^{-1}(|\mathbf{q}|) + F_1 \Pi(\Omega, \mathbf{q}) + F_2 \Pi_{\text{Dirac}}(\Omega, \mathbf{q})} (18)
$$

where $\Pi(\Omega, \mathbf{q})$ is given by [\(8\)](#page-1-2), and

$$
\Pi_{\text{Dirac}}(\Omega, \mathbf{q}) = \frac{1}{16v_x v_y} \frac{v_x^2 q_x^2 + v_y^2 q_y^2}{\sqrt{\Omega^2 + v_x^2 q_x^2 + v_y^2 q_y^2}}, \quad (19)
$$

$$
F_1 = e^{-\frac{v_y \Lambda}{d_y \Lambda^3}} = e^{-\frac{v_y}{d_y \Lambda^2}}, \tag{20}
$$

$$
F_2 = e^{-\frac{uy^{\Lambda}}{vy^{\Lambda}}} = e^{-\frac{uy^{\Lambda}}{vy}}, \qquad (21)
$$

where Π_{Dirac} is the polarization induced by 2D Dirac fermions [\[2\]](#page-4-7). Considering the dressed Coulomb interaction, the RG equations for v_x and v_y become

$$
\frac{dv_x}{d\ell} = (C_1^\star - C_0^\star)v_x,\tag{22}
$$

$$
\frac{dv_y}{d\ell} = (C_2^{a*} - C_0^*) v_y,
$$
\n(23)

$$
\frac{d\alpha}{d\ell} = (-C_1^* + C_0^*)\,\alpha,\tag{24}
$$

where C_0^* , C_1^* , C_2^* , and C_2^{a*} are the functions of α , β , and δ [\[83\]](#page-6-7). The RG flows of $v_x(\ell), v_y(\ell), v_y(\ell)/v_x(\ell)$ and $\alpha(\ell)$ considering of screen from polarization functions are shown in Figs. $2(e)-2(h)$ $2(e)-2(h)$ $2(e)-2(h)$. We can find that these RG flows have the qualitatively same behaviors as the ones shown in Figs. $2(a)-2(d)$ $2(a)-2(d)$ $2(a)-2(d)$.

Generation of excitonic gap. If the Coulomb interaction is strong enough, an excitonic gap can be generated [\[84](#page-6-8)[–93\]](#page-6-9). In order to study the generation of excitonic gap, we employ the Dyson-Schwinger equation method [\[84](#page-6-8)[–91\]](#page-6-10). The gap equation to lowest order can be written as

$$
\Delta(p_x, p_y) = \frac{1}{2} \int \frac{d^2 \mathbf{k}}{(2\pi)^2} \frac{\Delta(k_x, k_y)}{\sqrt{v_x^2 k_x^2 + d_y^2 k_y^6 + \Delta^2(\omega, k_x, k_y)}}
$$

$$
\times V_0(\mathbf{p} - \mathbf{k}).
$$
(25)

Through numerical calculation, we can find that excitonic gap $\Delta(p_x, p_y)$ is dynamically generated if the Coulomb interaction α is larger enough. Relations between $\Delta(0,0)$ and α with different values of β are pre-sented in Fig. [3\(](#page-3-0)a). It is easy to notice that $\Delta(0,0)$ becomes finite if α is larger than a critical value. Dependence of $\Delta(p_x, p_y)$ on p_x and p_y is shown in Fig. [3\(](#page-3-0)b).

FIG. 3: (a) and (b) $\Delta(0,0)$ and $\Delta(p_x, p_y)$ calculated by bare propagator of Coulomb interaction. (c) and (d) $\Delta(0,0)$ and $\Delta(p_x, p_y)$ calculated by dressed Coulomb interaction including the screen of polarization. In (b) and (d), $\alpha = 0.5$ and $\beta = 1$ are taken.

We find that $\Delta(p_x, p_y)$ approaches to a constant value $\Delta(0,0)$ when p_x and p_y approach to zero. $\Delta(p_x, p_y)$ drops quickly when vp_x or $\dot{d}_y p_y^3$ is larger than the energy scale given by $\Delta(0,0)$.

Considering the correction from polarization to lowest order, the dressed Coulomb interaction becomes

$$
V(\Omega, \mathbf{q}) = \frac{1}{V_0^{-1}(\mathbf{q}) + \Pi(\Omega, \mathbf{q})},\tag{26}
$$

where $\Pi(\Omega, \mathbf{q})$ is given by Eq. [\(8\)](#page-1-2). Employing the instantaneous approximation [\[84](#page-6-8)[–86\]](#page-6-11), the Coulomb interaction becomes

$$
V(\mathbf{q}) = \frac{1}{V_0^{-1}(\mathbf{q}) + \Pi(0, \mathbf{q})}.
$$
 (27)

Replacing $V_0(\mathbf{q})$ in Eq. [\(25\)](#page-2-1) with $V(\mathbf{q})$ as shown in Eq. [\(27\)](#page-3-1), we obtain the gap equation considering the screening from polarization function under instantaneous approximation. Dependence of $\Delta(0,0)$ on α and dependence of $\Delta(p_x, p_y)$ on momenta p_x and p_y considering screen from polarization function are presented in Figs. [3\(](#page-3-0)c) and 3(d) respectively. Comparing Fig. 3(c) with $3(a)$, and $3(d)$ with $3(b)$, we can find that the magnitude of excitonic gap is suppressed if the screening from polarization is considered.

Observable quantities. For free linear-cubic fermion system, the observable quantities including density of states $\rho(\omega)$, specific heat $C_v(T)$, compressibility $\kappa(T)$, diamagnetic susceptibility $\chi_D(T)$, and optical conductivities along the two directions $\sigma_{xx}(\omega)$ and $\sigma_{yy}(\omega)$ take the behaviors [\[83\]](#page-6-7)

$$
\rho(\omega) \propto \omega^{1/3}, \qquad C_v(T) \propto T^{4/3},
$$

\n
$$
\kappa(T) \propto T^{1/3}, \qquad \chi_D(T) \propto T^{-1/3},
$$

\n
$$
\sigma_{xx}(\omega) \propto \omega^{-2/3}, \qquad \sigma_{yy}(\omega) \propto \omega^{2/3}, \qquad (28)
$$

where ω represents the energy, and T is the temperature.

Under weak Coulomb interaction, the system takes the similar behaviors as 2D Dirac semimetal with Coulomb interaction. Thus, the observable quantities can be written as [\[2](#page-4-7), [94](#page-6-12)]

$$
\rho(\omega) \propto \frac{\omega}{\ln^2\left(\frac{\omega_0}{\omega}\right)}, \qquad C_v(T) \propto \frac{T^2}{\ln^2\left(\frac{T_0}{T}\right)},
$$
\n
$$
\kappa(T) \propto \frac{T^2}{\ln^2\left(\frac{T_0}{T}\right)}, \qquad \chi_D(T) \propto \frac{\ln^2\left(\frac{T_0}{T}\right)}{T},
$$
\n
$$
\sigma_{xx,yy}(\omega) \propto \sigma_0 \left[1 + \frac{\tilde{C}\alpha}{1 + \alpha \ln\left(\frac{\omega_0}{\omega}\right)}\right]. \qquad (29)
$$

If the Coulomb interaction is strong enough, an excitonic gap Δ is generated. Then the observable quantities take the behaviors [\[83](#page-6-7)]

$$
\rho(\omega) \propto \frac{|\omega|}{(\omega^2 - \Delta^2)^{\frac{1}{3}}} \theta(|\omega| - \Delta),
$$

\n
$$
C_v(T) \propto \frac{\Delta^{\frac{10}{3}}}{T^2} e^{-\frac{\Delta}{T}},
$$

\n
$$
\kappa(T) \propto \frac{\Delta^{\frac{4}{3}}}{T} e^{-\frac{\Delta}{T}},
$$

\n
$$
\chi(T) \propto \frac{1}{\Delta^{\frac{1}{3}}},
$$

\n
$$
\sigma_{xx}(\omega) \propto \frac{1 + 12\frac{\Delta^2}{\omega^2}}{(\omega^2 - 4\Delta^2)^{\frac{1}{3}}} \theta(|\omega| - 2\Delta),
$$

\n
$$
\sigma_{yy}(\omega) \propto (\omega^2 - 4\Delta^2)^{\frac{1}{3}} \left(1 + \frac{20}{3}\frac{\Delta^2}{\omega^2}\right) \theta(|\omega| - 2\Delta)(30)
$$

The behaviors of $C_v(T)$, $\kappa(T)$, and $\chi_D(T)$ are valid in the limit $T \ll \Delta$.

Considering the excitonic gap Δ , the Hamiltonian can be written as

$$
\mathcal{H}_{\Delta} = D_x \sigma_x + D_y \sigma_y + D_z \sigma_z, \tag{31}
$$

where the vector **is defined as**

$$
\mathbf{D} = v_x k_x \mathbf{e}_x + d_y k_y^3 \mathbf{e}_y + \Delta \mathbf{e}_z.
$$
 (32)

The topological property of this Hamiltonian is determined by the unit vector

$$
\hat{\mathbf{D}} = \frac{\mathbf{D}}{|\mathbf{D}|} = \frac{v_x k_x \mathbf{e}_x + d_y k_y^3 \mathbf{e}_y + \Delta \mathbf{e}_z}{\sqrt{v_x^2 k_x^2 + d_y^2 k_y^6 + \Delta^2}}.
$$
(33)

The corresponding Chern number is given by [\[95](#page-6-13), [96](#page-7-0)]

$$
C = \frac{1}{4\pi} \int d^2 \mathbf{k} \left(\frac{\partial \hat{\mathbf{D}}}{\partial k_x} \times \frac{\partial \hat{\mathbf{D}}}{\partial k_y} \right) \cdot \hat{\mathbf{D}}.
$$
 (34)

Substituting the expression of $\hat{\mathbf{D}}$, we can get

$$
C = \frac{1}{4\pi} \int d^2 \mathbf{k} \frac{3v_x d_y k_y^2 \Delta}{\left[v_x^2 k_x^2 + d_y^2 k_y^6 + \Delta^2\right]^{\frac{3}{2}}}.
$$

= $\frac{1}{2} \text{sgn}(v_x) \text{sgn}(d_y) \text{sgn}(\Delta).$ (35)

$$
\sigma_{xy} = C \frac{e^2}{h},\tag{36}
$$

where h is the Planck constant. The system becomes a novel excitonic Chern insulator under strong Coulomb interaction.

Discussion. In summary, we study the influence of long-range Coulomb interaction on an anisotropic flat band fermion with a dispersion which is linear along one direction and cubic along another. Based on RG theory, we show that the fermion velocity is always restored along the direction which has cubic dispersion originally. Accordingly, the system takes the qualitatively same behaviors as the 2D Dirac fermion system with Coulomb interaction. Through self-consistent Dyson-Schwinger gap equation method, we find that the system is driven to excitonic Chern insulator phase if the Coulomb interaction is strong enough.

In Ref. [\[60\]](#page-6-3), there is a term $k_x^2 k_y \sigma_2$ for the Hamiltonian. In this Letter, we neglect this term to simplify the calculation. Our conclusions will be not changed qualitatively if this term is considered.

Due to vanishing of density of sates at the Fermi level, weak four-four interaction is irrelevant in the view of RG theory, but strong four-fermion interaction could become relevant and drive the system to a new phase. Considering four-fermion interaction $g_3(\psi^{\dagger} \sigma_3 \psi)^2$, through analysis of mean-field method, we find that an excitonic gap Δ is generated if g_3 is larger than a critical value g_{3c} , and it takes the form $\Delta \propto (g_3 - g_{3c})^3$ [\[83](#page-6-7)].

Studies about the interplay of Coulomb interaction and short-range four-fermion interaction, and the quantum critical behaviors between the gapless anistropic band fermion phase and excitonic Chern insulator phase are also interesting.
