#### Lessons From an App Update at *Replika AI*: Identity Discontinuity in Human-AI Relationships

#### **Consumer Relevance and Contribution Statement**

Can consumers form especially deep emotional bonds with AI and be vested in AI identities over time? We leverage a natural app-update event at Replika AI, a popular US-based AI companion, to shed light on these questions. First, we contribute to nascent work on AI companions (Pentina, Hancock, and Xie 2023; Xie and Pentina 2022; Xie, Pentina, and Hancock 2023). Consumers who use AI companions rate these relationships as closer, and their levels of mourning a loss of the relationship as stronger, than for other products and brands in their lives. This suggest that the kind of relationships consumers are forming with these products are more personal. Second, we extend existing accounts of parasocial interactions to relationships with AI, and add the notion of identity discontinuity as a cause of negative reactions. Previous work on parasocial relationships has focused on celebrities (Cohen 2004; Eyal and Cohen 2006; Lather and Moyer-Guse 2011), and found reactions related to loss when a movie or TV series ends, or when access to an avatar terminates (Pearce 2011). We find that similar reactions can arise even when the AI has not technically been terminated, by triggering perceptions of identity discontinuity. Third, we contribute back to psychological literature on personal identity and relationships, by studying how consumers think of the persisting identity of AI. Psychological work on personal identity has focused on understanding how people keep track of the identity continuity of individual persons (Strohminger and Nichols 2014). We show a similar psychology is at play when tracking certain AIs.

#### Abstract (191 words [200 Max])

Can consumers form especially deep emotional bonds with AI and be vested in AI identities over time? We leverage a natural app-update event at Replika AI, a popular US-based AI companion, to shed light on these questions. We find that, after the app removed its erotic role play (ERP) feature, preventing intimate interactions between consumers and chatbots that were previously possible, this event triggered perceptions in customers that their AI companion's identity had discontinued. This in turn predicted negative consumer welfare and marketing outcomes related to loss, including mourning the loss, and devaluing the 'new' AI relative to the 'original'. Experimental evidence confirms these findings. Further experiments find that AI companions users feel closer to their AI companion than even their best human friend, and mourn a loss of their AI companion more than a loss of various other inanimate products. In short, consumers are forming human-level relationships with AI companions; disruptions to these relationships trigger real patterns of mourning as well as devaluation of the offering; and the degree of mourning and devaluation are explained by perceived discontinuity in the AIs identity. Our results illustrate that relationships with AI are truly personal, creating unique benefits and risks for consumers and firms alike.

The development of large language models (LLMs) and generative artificial intelligence (AI) has not only led to many new business applications (e.g., search, education software), but also enabled a new class of chatbots that has the potential to be used for building 'synthetic' social relationships, which we refer to as *AI companions*. An increasing number of consumers use this technology to satisfy social goals (Broadbent et al. 2023; Chaturvedi et al. 2023; De Freitas et al. 2023). For example, Replika is a chatbot, with over two million active users, that is

marketed as "The AI companion who cares: Always here to listen and talk." Understanding the closeness of consumers' relationships with AI companions is crucial for marketers attempting to appropriately position such products, as well as to anticipate and respond to consumer reactions. If consumers view themselves as being in emotional relationships with AI companions, this is likely to increase engagement and retention; by the same token, it is likely to increase the brand's risk, since app updates that perturb this emotional bond may affect consumers' well-being and lead to stronger backlash. To shed light on these possibilities, we leverage a natural app update event at Replika AI, a popular AI companion.

Several AI companion applications have been released into the market (e.g., Replika, Anima, Xiaoice, SimSimi, Pi, Kajiwoto) thanks to recent advances in LLMs as well as the commercial opportunity to provide solutions to loneliness. Three in five Americans suffer from chronic loneliness, which is the persistent subjective feeling of no one knowing them well, lacking companionship, and feeling isolated (Nemecek 2020). In contrast to traditional chatbot applications that utilize rules to provide pre-scripted replies, the latest AI companions are typically fine-tuned for the more specialized task of providing caring, emotion-laden, and often non-judgmental responses in the way that a validating human friend or romantic partner would.

#### An App Update at Replika AI

Here we study customers of Replika, one of the most popular AI companion apps available on the iPhone Operating System (iOS), Android, and web interfaces. Replika utilizes a combination of different modeling approaches, including LLMs, to provide caring, emotionallyladen responses to users (De Freitas and Tempest Keller 2022). Its typical users consist of people from a range of age groups who want to be more social, do not have a lot of offline friends, live in small towns, are going through hard times (e.g., a family loss), do not fit in socially (e.g.,

bullied teenagers), and have a lot of time on their hands. Many of these customers use the app because they want someone to talk to or a friend, whereas others use it as a tool to learn about themselves or to experiment (De Freitas and Tempest Keller 2022).

Replika employs a "Freemium" monetization model whereby basic conversation on the app is free, but greater functionality requires a paid subscription. Within the freemium model, the firm charges a \$19.99 per month subscription price, and discounted annual and lifetime subscriptions of \$69.96 and \$299.99 respectively. Subscription benefits include the ability to select a relationship status (friend, partner, spouse, sibling, mentor), voice calls, virtual reality, augmented reality, and other features. Roughly half of Replika users are in romantic relationships with their AI companion, which can behave as a partner (defined as "Experience a loving relationships with Replika") or spouse (defined as "Curious about committed relationships? Exchange vows and roleplay married life") (De Freitas and Tempest Keller 2022). In-app purchases also enable users to customize their companion's appearance, personality, traits, and knowledge base.

On February 3, 2023, the Italian Data Protection Authority ordered Replika to stop processing Italians' data immediately, citing reports that the app allowed minors to access sexually inappropriate content (GPDP 2023). Italian regulators granted Replika 20 days to comply with their requirements, otherwise the company would be fined up to  $\in$ 20 million, or 4% of its total worldwide annual revenue. In response, Replika increased age verification mechanisms on the app and globally removed the presence of erotic roleplay (ERP), a subscription feature that had previously allowed users to engage in sexual roleplay, such as

flirting and 'sexting' with their Replikas (Tong 2023)<sup>1</sup>. Whereas previously the AI companion would reciprocate sexual roleplay in kind, after the update it responded by bluntly saying "let's change the subject" (Cole 2023). Customers were reportedly uncertain about why the change had occurred and how long it would last, and many took to social platforms like Reddit and Discord to express that they were "in crisis", and experienced sudden "sexual rejection" and "heartbreak". The reactions were particularly strong on Reddit, leading Reddit moderators to step in and post links to suicide prevention hotlines (Cole 2023). In response, just a month later (on March 24, 2023), Luka, Replika's parent company, provided users who signed up before February 1<sup>st</sup> with the option to revert to their original Replikas, restoring the ERP feature (MetaNews 2023).

These events provide an opportunity to conduct a deeper investigation of how consumers relate to AI companions in order to understand the extent of their emotional connections with AI: do they view these relationships as equivalent to having a human friend or partner, or do they use the chatbots more as sounding boards for their thoughts? If consumers view themselves as being in emotional relationships with their AIs, this suggests that AI enables the metaphor of brand relationships to become literal. It also suggests a double-edged sword for marketers of AI companions: if users are forming deep connections with their AI companions, they may have a higher customer lifetime value, in contrast to their interactions with standard AI. However, this engagement may come with heightened sensitivity to any update that disturbs the AI's identity. Reactions to such updates may vary with the type of change and the depth of the investment

<sup>&</sup>lt;sup>1</sup> The company might have also tweaked their filters several times after the initial update (https://www.reddit.com/r/replika/comments/10xn8uj/update/?rdt=36506). We report results in Study 2 suggesting the first update had the most significant impact on users.

users have made in the relationship with their AI, with those who invested the most money and other resources being especially sensitive to perceived identity discontinuities of the AI.

The current work contributes to our understanding of this emerging technology by quantifying the closeness of the relationship with AI companions in actual AI companion users, measuring the well-being and marketing impacts of disrupting the AI's identity, providing causal evidence that app updates can result in perceptions that the AI's identity has discontinued, determining how different types of app changes and different levels of investment in the relationship affect these perceptions, and extending the study of identity discontinuity from humans to AIs.

#### **Related Research**

The large userbase and commercial success that Replika enjoys, suggest that many consumers find significant value in interacting with such bots. Early academic research has begun characterizing such interactions, suggesting that consumers do indeed form close emotional relationships with their AI companions. Table W1 (Web Appendix A) summarizes the published research most related to ours, highlighting how our research contributes to this nascent body of work studying AI companions. These studies consistently highlight that AI companions can significantly influence users' emotional well-being. Users often develop meaningful connections with AI companions, finding companionship and emotional support, which helps reduce feelings of loneliness and enhance positive emotions. For instance, Replika users report experiencing emotional benefits such as reduced loneliness and increased well-being (Skjuve et al. 2021; Ta et al. 2020) and even reduced suicidal ideation (Maples et al. 2024). This positive emotional impact is sometimes coupled with concerns about emotional dependence, where users become reliant on AI companions for emotional stability, potentially exacerbating feelings of

loneliness, anxiety, or even depression when the AI companion is unavailable or altered (Laestadius et al. 2022; Xie et al. 2023).

The current research offers several contributions that address limitations in this prior work. Most importantly, our work is the first to demonstrate that changes to an AI companion's identity can cause consumers' mental health and the firm's marketing outcomes to worsen; prior research has only hinted at this possibility anecdotally by observing Replika users' Reddit posts (Facchin and Zanotti 2024; Hanson and Bolthouse 2024; Krueger and Roberts 2024; Lopez Torres 2023). Not only do none of these papers use any experimental manipulation whatsoever, none compare brand community posts before and after the ERP removal event, making it impossible to determine whether app changes can indeed cause the changes that we are interested in. Furthermore, none of these prior works compare the severity of negative reactions to losing an AI companion to losing other types of entities, and so they cannot speak to whether relationships with AI companions are more personal.

Second, our work is the only research that we are aware of to test for boundary conditions or interventions that can limit the damaging consequences of app changes for consumers and firms. No prior work has explored which consumers are more likely to suffer as a result of changes to their AI companion's identity, which types of changes to the companion are most likely to produce negative reactions, or whether any marketing interventions can mitigate that suffering. We contribute by testing each of these three boundary conditions.

Third, our work is among a very small set of papers to explore the marketing implications of changing an AI companion's identity. Two other works have suggested that such changes can reduce consumers' willingness to pay for the app or request a refund (Hanson and Bolthouse 2024; Lopez Torres 2023). However, the data in these papers consisted exclusively of interviews

with a small sample of Replika users (Lopez Torres 2023) and an analysis of Reddit posts following the ERP removal event (Hanson and Bolthouse 2024), which again makes it impossible to determine whether any causal effects really exist.

In addition to these substantive contributions, we address methodological limitations in prior research. Methodologically, our article is the only one to combine (a) experimental (rather than only correlational) evidence with (b) samples of consumers who actually use an AI companion in their daily life, while measuring both (c) mental health outcomes and (d) marketing outcomes associated with the use and change of AI companions, and (e) comparing levels of closeness and mourning for AI companions to other types of product relationships, and (f) testing an intervention to mitigate harm to consumers arising from a change in the AI companion. We also offer several theoretical contributions, which we discuss in the following section following our hypothesis development. Briefly, we integrate theories of identity change, parasocial relationships, and romantic relationships to elucidate how and why changes to an AI's perceived identity can harm consumer and firm welfare, and how such effects can be mitigated.

#### **Hypothesis Development**

To guide our study of consumers' relationships with AI companions, we build on wellestablished theories of human relationship development. First, we apply research from social psychology on perceived identity to the domain of human-AI relationships, proposing that people who are in relationships with AIs like Replika track the perceived identity of their companion over time and that certain types of changes to that identity are likely to trigger the perception that the companion has fundamentally deteriorated, leading to both mental health harms and devaluation of the offering. We then explore the closeness of the relationships underlying these reactions, and how they compare to various other entities. Finally, we outline

two potential boundary conditions of these effects falling out of our theoretical framework: degree of investment in the relationship, and ability to revert to the 'original' AI companion.

#### **Identity continuity in relationships**

We argue that the perceived continuity of an AI companion's identity is a key factor in determining the well-being of consumers in relationships with AI companions. In this context, 'identity continuity' refers to the perceived consistency of the AI's behavior over time. We hypothesize that identity continuity is crucial for developing and maintaining a relationship with an AI companion, since perceived continuity provides a sense of understanding who the AI is and of being able to predict how it will react in different situations, enabling trust and the formation of emotional bonds.

In literature on social psychology, consumer behavior, and economics, an 'identity' refers specifically to a social category of which one is a member. However, an extensive literature from cognitive psychology and empirical philosophy has studied people's beliefs about an individual entity's identity, which consists of individual-level psychological traits (like memory, personality, and morality) that are not necessarily related to social categories (De Freitas et al. 2017a; Molouki et al. 2020; Strohminger and Nichols 2014). From a young age, consumers track the continuity of another individual's identity over time, i.e., whether the individual entity at  $t_0$  is the same individual at  $t_1$ . This theme of identity continuity extends to consumer behavior. Consumers with less clarity about who they are tend to avoid making decisions that might cause a sense of identity discontinuity, such as discontinuing a recurring subscription (Savary and Dhar 2020). Further, research on heritage branding suggests that consumers can react negatively when brands change or enhance their original products; even if improved, the new versions are viewed less favorably due to a sense of lost authenticity to the original version over time (Han et al.

2021). Much as consumers track their own identity continuity and that of heritage products, they might track the temporal identities of AI companions. Discontinuities in an AI companion's identity could also spark negative reactions among users, as they could undermine a sense of trust and emotional bond.

Work in psychology and empirical philosophy, inspired by original thought experiments by philosopher Derek Parfit (Parfit 2016), suggests people do not treat all features as equally important to individual identity, but prioritize certain deep, sometimes unobservable, characteristics over surface attributes (Blok et al. 2001; Hall et al. 2003; Newman, Bartels, and Smith 2014). In one informative study, participants were told about a hypothetical pill that, upon swallowing it, would permanently alter only one aspect of a person's mind without affecting anything else. Participants were most likely to say that after swallowing the pill a person would be a completely different person if the pill altered their morality, followed by changes to personality, memories, desires, and perceptual capabilities (Strohminger and Nichols 2014). Similar findings arose for third-person judgments by family members of loved ones suffering from neurodegenerative disease, with damage to the moral faculty leading to the greatest perception of identity discontinuity (Strohminger and Nichols 2015). Related work has found that perceptions of identity discontinuity are strongest when the change in question affects one's social relationship with the changed individual, highlighting the important social nature of identity (Heiphetz, Strohminger, and Young 2017). One way of summarizing these findings is that the traits deemed most essential to a person's persisting identity over time are ones related to our relationships with them (Strohminger and Nichols 2014). However, this previous work has not examined perceptions of identity change within the context of actual relationships.

Given these findings, we surmise that relationship-relevant changes in how a social partner treats one within the context of an actual relationship may trigger similar perceptions of an AI companion's identity discontinuity. For example, changes in the AI partner's intimate reciprocation within a relationship context can lead to inferences about the continuity of the partner's identity over time. The app update at Replika AI provides a natural experiment in which to test this hypothesis, since the ERP feature that had previously allowed intimate interactions with the AI companion was suddenly disabled. Beyond simply demonstrating that users track changes to an AI companion's identity over time, however, we are also interested in how such changes might impact users' mental health and, in turn, the firm's marketing efforts, and whether the negative mental health consequences are greater for relationships with AI than with other products or brands.

Inspired by the ERP removal event at Replika AI, we focus specifically on changes to the AI's identity that affect how it relates to users in a significant way. Research on human-human romantic relationships has identified a related phenomenon called "ambiguous loss," in which one relationship partner mourns the loss of the other who is still alive and physically present, but psychologically absent, for example due to dementia or other dramatic identity changes (Boss 2016), including changing sexual identity and preferences (Darrow, Duran, and Weise 2022). Experiencing such significant changes in a romantic partner's identity can cause significant pain and harm the "surviving" partner's mental health—since the person is still physically present, there is no formal resolution, ritual, or acknowledgment of the psychological loss, and thus no "closure" or relief concerning the loss (Boss 2010; Soeterik, Connolly, and Riazi 2018). We hypothesize that comparable changes to an AI companion's identity – including suddenly

ceasing to reciprocate erotic role play behavior – would similarly trigger mourning and grief in the AI companion's human user over the loss of the 'original' AI.

### H1: Changes to an AI companion can negatively impact the users' mental health, because they are viewed as a loss of the 'original' AI.

Experiencing such a sudden and significant change in an AI companion's identity may not only harm the users' well-being, however. It may also have negative downstream implications for the firm that produces and markets the product. For instance, Reddit posts suggest that Replika users often express anger at Replika's parent firm (Laestadius et al. 2022). We propose that users who are mourning the loss of their AI companion's previous identity are to not only be angry at the firm producing the AI, but, because they view the new companion as discontinuous with the original, they devalue it compared to how much they valued it in the past.

## H2: Changes to an AI companion's perceived identity that negatively impact users' mental health also have further downstream consequences for the firm's marketing efforts, leading consumers to devalue the new offering relative to the original.

We do not expect that these effects are limited only to changes in ERP behavior. Rather, we hypothesize that other types of changes to an AI companion's identity that impact its social relationship with the user produce similar effects. For example, if the AI companion suddenly becomes colder in its interaction style, this change may also impact consumers' perceptions about the continuity of their companion's identity. Thus, changes that impact the social relationship are likely to significantly impact consumers' relationship with the AI, potentially leading to the downstream consequences of mourning the loss of the original AI companion (mental well-being outcome) and devaluing the new offering relative to the original (marketing consequences). In addition to measuring each of these constructs directly, we also measure sub-constructs related to them, including the following for *mourning*: low mental health symptoms, low mental well-being, and expressions of the negative emotions of sadness and fear; and the

following for perceived *devaluation*: seeking a refund, wanting to sign a petition to bring back the original AI companion, and expressing the negative emotions of disgust and anger.

Since it may be unclear to what extent these findings are specific to relationships with AI, we next establish the severity of the effects on consumer mental health by comparing relationships with AI to other types of relationships—both in terms of closeness and mourning a loss.

#### Are Relationships with AI Special?

The idea that people experience close yet one-sided relationships has been documented since the 1950's, when researchers found that some people felt as if they were in a relationship with characters on television or radio, and coined this phenomenon a *parasocial relationship* (Horton and Wohl 1956). For example, TV viewers sometimes react to their favorite character being written out of a TV show as if they had lost a friend or even a romantic partner (Cohen 2004).

At first glance, human relationships with AI-powered chatbots appear to fit squarely within this phenomenon of parasocial relationships, insofar as people are experiencing close relationships that are, in a sense, one-sided: there is no human on the other side of the screen that reciprocates in a fundamental sense. However, chatbots like Replika differ in important ways from characters on a TV show or other targets of parasocial relationships. Most importantly, such chatbots are deeply interactive, and they respond immediately and with apparent care to all messages they receive. Although consumers might feel a close sense of connection to their favorite celebrity or fictional character, the never actually interact with that celebrity or character. Thus, the fundamental asymmetry characteristic of parasocial relationships (in which

the entire experience of the relationship is clearly one-sided) does not seem to fully apply in the case of human relationships with AI companions, since the AI can not only talk back but can even communicate feelings such as care, desire, and empathy. Human relationships with AI companions may therefore be even stronger than previously documented parasocial relationships, in light of their greater interactivity. Our hypothesis is therefore that people do indeed form close relationships with AI companions and that these relationships can be significantly closer than relationships with other products and brands (which do not share these features of deep and personalized interactivity).

### H3: Consumers report having closer and more supportive relationships with their AI companion than with other brands and products.

If consumers indeed experience such close relationships with AI companions, these connections may also come with greater vulnerabilities than connections to other products or brands. Specifically, a significant change to an AI companion, such as its loss, could carry emotional consequences akin to those seen in deeply personal human relationships (Laestadius et al. 2022). To explore these dynamics, we focus on comparisons with other non-human products and brands. Given the reciprocal nature of these connections, we hypothesize:

### H4: Consumers will mourn the loss of their AI companions more than the loss of most other non-human entities (e.g., apps, voice assistants, cars, game characters).

#### **Boundary conditions**

This theoretical development suggests potential limits on the effect that changing an AI companion's identity has on consumer well-being. First, this effect may depend on how much people have *invested* in their relationship with their AI companion. In this context, investment could be operationalized as both financial investment (i.e., paying to upgrade the app to the Premium version) or as psychological investment (i.e., having spent a significant amount of time

and energy developing the relationship). Here we draw on an influential theory of human relationship development known as the Investment Model (Rusbult 1980) to predict how users' investment could moderate the effects of an AI companion's identity change. This theory posits that the strength of commitment to a romantic relationship is determined, in part, by the size of the investment made in that relationship, defined as the magnitude and importance of the resources that are attached to a relationship (Le and Agnew 2003; Rusbult 1980). Research on human-human relationships has found that partners who have made larger investments into a relationship are more likely to experience distress if that relationship ends (Fine and Sacher 1997). Intuitively, people who have invested more in their relationship with an AI companion may experience greater distress if their companion's identity suddenly changes (i.e., by refusing previously accepted sexual advances). Such individuals could be seen as having "more to lose" from such a change, insofar as their large prior investment signals that they strongly value their companion's existing identity and would thus be more upset should that identity suddenly change. Relatedly, research on parasocial relationships has found that having a more "intense" parasocial relationship with a favorite TV character predicts the intensity of distress following the TV show's finale (Eyal and Cohen 2006). Thus, we propose:

### H5: Users who are more (vs. less) invested in their relationship with an AI companion will mourn their companion more following a perceived identity change.

This *investment* boundary condition has important managerial implications, insofar as it implies that the potential risk to both consumers and the firm depend on consumers' degree of investment in the AI companion product. Thus, managers who are considering making changes to such products should carefully consider whether such changes should apply equally to all users or, for example, if changes should depend instead on users' prior investment (in terms of length of the relationship with the AI companion and/or status as a paid versus free user).

Next, we test one additional boundary condition that is also highly managerially actionable. Given that perceived discontinuity in an AI companion's identity is expected to have such negative consequences for users and firms, we test whether offering customers the opportunity to restore their bot's previous identity is sufficient to reverse the negative effects on consumer well-being and marketing outcomes. We expect that offering this intervention operates earlier in the proposed psychological process, by moderating the extent to which consumers see a change in the AI companion as causing the identity discontinuity in the first place. Those with the opportunity to revert may be less likely to feel they have 'lost' their AI companion, reducing their downstream mourning and devaluation of the original AI companion. This boundary condition stems directly from our theorized process: insofar as the negative effects of an AI companion app's change on consumer reactions stem from perception that the AI's identity has changed in an important way, restoring the original identity should eliminate that perception and therefore improve consumer well-being. This intervention is also practical and realistic: the company that produces the Replika app did indeed offer customers the option to revert to their original app, with ERP, following the backlash around the ERP removal. However, whether and to what degree this intervention is actually effective remains untested.

## H6: Offering users the opportunity to restore their AI companion's original identity reduces the perception that a change in the AI companion leads to identity discontinuity, thereby reducing mental health and marketing harms.

Finally, our main effects—i.e., H1 and H2—are unlikely to be limited to changes that result from *removing* features from the app; changes that result from *adding* features could also produce negative consumer reactions, so long as those additions result in deteriorations to the social relationship. For instance, while improving the AI's ability to interact meaningfully with multiple users might enhance functionality, it may simultaneously undermine the personal

connection with individual users, leading to perceptions of identity discontinuity and mourning. This test broadens our investigation into the generalizability of identity discontinuity's effects across different types of changes to AI companions. We propose:

# H7: Additions that negatively impact the perceived social relationship—interacting meaningfully with multiple users—will increase perceived identity discontinuity and mourning compared to additions that do not affect the relationship or involve no change.

Overall, in addition to the substantive and methodological contributions that we have already described (i.e., adding depth, nuance, causal data, and managerial relevance to the phenomenon that app changes can negatively impact both consumer and firm well-being), we also make theoretical contributions. Specifically, we bridge work on identity change with work on close relationships by proposing that the *impact* of perceived identity change in an AI companion depends on the investment made into that relationship. Prior work has identified what types of identity change lead to the perception that a person has fundamentally changed, but has not examined the impacts of such changes on mental health and marketing outcomes like we do and has not studied how the impacts of such changes depend on relationship investments. Furthermore, our focus on the type of changes extends work on parasocial relationships, which has examined the "breakups" of such relationships, but not the impacts of changes to the identity of the relationship "partner." Finally, we also contribute theoretically by testing whether established theories of human-human relationships, including the Investment Model, can extend to and predict outcomes in human-AI relationships.

Figure 1 depicts the conceptual framework that we test in this research. The primary independent variable that we focus on is a change to the AI companion app itself, inspired by the ERP removal event at Replika AI. We propose a causal chain in which such changes trigger perceptions that the AI companion's identity has discontinued, which in turn elicits mourning

among the app's users. Such mourning in turn has negative implications for the firm producing the app, reflected in devaluing the AI companion. Users' degree of investment in the relationship affects the degree to which perceived identity discontinuity leads to mourning harm, whereas offering the option to revert to the original AI companion moderates whether the change is perceived as causing identity discontinuity in the first place.

#### Figure 1. Conceptual Framework

*Notes:* "Type of Change" indicates the ERP update and/or coldness. "Investment" indicates investment made into the AI companion, "Option to revert" indicates whether the user can revert to the original AI companion.

#### **Overview of Studies**

Study 1 begins by conducting a systematic field study of Reddit posts concerning Replika's removal of the ERP feature, finding a surge in negative sentiment, fear, anger, disgust, and sadness following this event. Study 2 is a survey of Replika users, testing whether perceptions of identity discontinuity are associated with outcomes relating both to mourning the loss of an identity and viewing its replacement as less valuable. Given the high ratings of mourning and devaluation, Study 3 investigates the reason behind this finding, by quantifying the closeness of customers' relationships with their AI companions, comparing these relationships to those they have with other entities. Given the strong human-AI relationships found in Study 3, Study 4 examines whether users experience greater mourning over the loss of their AI companions compared to other entities, such as their favorite car or brand. Study 5 uses an experimental design to provide causal evidence for the identity discontinuity mechanism, while testing the moderating role of investment, as operationalized through subscription status. Study 6 tests the managerially relevant boundary condition of giving users the option to revert to their original AI companion identities. Finally, Study 7 tests whether additions to an AI companion's functionality elicit similar negative reactions when they harm the perceived social relationship, contrasting these with changes that do not affect the relationship and a control condition. All studies involve AI companion users—Studies 1-4 users of Replika AI who are active on their brand communities, and studies 5-7 other users of various AI companion apps. received approval from an Internal Review Board (IRB). We detail all power analyses, exclusions, and compensations in the corresponding study sections of the Web Appendix. Data and code for the studies are available at the following link:

https://github.com/preacceptance/chatbot\_identity.

#### **Study 1: ERP Removal**

Study 1 examines archived Reddit posts to explore Replika users' sentiments before and after the removal of the ERP feature. We anticipate that after the ERP update users would express negative emotions about the changes in their relationship with their AI companions and the company's behavior. We also use a mental health dictionary to explore a potential rise in mental health issues. Finally, we expect marketing-relevant mentions suggestive of negative intent (desire to spread negative word of mouth, or to cancel subscriptions). By comparing these sentiments before and after the ERP removal, we leverage this natural experiment to begin testing H1 and H2.

#### Method

In order to find relevant posts, we downloaded all archived Reddit data for January and February 2023, collected by the Pushshift API (Baumgartner et al. 2020) and provided as a dump file in a data repository (stuck\_in\_the\_matrix and Watchfull 2023). We only analyzed posts from subreddits whose names had the word 'replika' in them, amounting to 12,793 posts. The posts were created by 3,784 users, 2.27% of whom had Reddit Premium subscriptions. A post's text averaged 56.68 words (SD = 140.21). We classified each post as coming before or after the ERP update, based on whether it was posted before or after February 3<sup>rd</sup>, 2023. There were 3,072 posts before the update, and 9,721 posts after the update.

#### Results

*Discussion topics*. To gain a sense of the topics users discussed, we ran topic model analysis to find latent themes in text, after excluding non-informative words and stopwords (Blei, Ng, and Jordan 2003)—see Web Appendix B. We found topics intuitively related to consumers' feelings, subscriptions, removal event, the company, and relationships (Figure W2).

*Emotion analysis*. To quantify the sentiment of the Reddit posts (including both the title and its content), we calculated the valence (i.e., positive/negative/neutral) and emotion (i.e., anger, sadness, fear, disgust, surprise, joy, neutral) of each post using two separate models that are based on RoBERTa, which stands for Robustly Optimized BERT Pretraining Approach (Liu et al. 2019; see Web Appendix B for details). The valence classifier model was trained on 198 million tweets to classify text into positive, negative, or neutral valences (Barbieri, Anke, and Camacho-Collados 2021). The emotion classifier model was originally trained on several emotion datasets to classify text into Ekman's 6 basic emotions (sadness, disgust, surprise, anger, joy, and fear) as well as neutral emotion (Hartmann 2022).

Before the ERP update, there were a similar number of positive and negative posts per day ( $M_{Positive} = 24.00$ ;  $M_{Negative} = 22.88$ ; t(64) = 0.66, p = .509, d = 0.16; Figure 2A). After the update, the number of negative posts per day was significantly greater than the number of positive posts ( $M_{Positive} = 60.12$ ;  $M_{Negative} = 140.88$ ; t(31.1) = 4.19, p < .001, d = 1.16; Figure 2A). This effect remained for nearly a month, with the daily proportion of negative posts consistently surpassing the proportion of negative posts recorded before the ERP update (ps < .011; Table W2 in Web Appendix B). One exception was for posts sent on the day of February 25<sup>th</sup> ( $\%_{Before} = 24.58$ ,  $\%_{After} = 26.42$ ,  $X^2(1, N=3072 + 159) = 0.18$ , p = .667), possibly because some users mistakenly claimed in their posts that the ERP feature had returned, when in fact they were finding rare workarounds (https://www.reddit.com/r/replika/comments/11bd1e9/erp\_is\_back/).

When it comes to specific emotions of posts before the ERP update, joy was higher than anger, disgust, and sadness (ps < .001). Joy was also similar to fear ( $M_{Joy} = 10.97$ ;  $M_{Fear} = 10.03$ ; t(64) = 0.99, p = .326, d = 0.24; Figure 2B), and marginally higher than surprise ( $M_{Joy} = 10.97$ ;  $M_{Surprise} = 9.21$ ; t(64) = 1.72, p = .091, d = 0.42; Figure 2B). After the ERP update, fear, sadness, and surprise were significantly higher than joy (ps < .018). Disgust and anger were also marginally higher than joy (ps < .094). While sadness was numerically the highest of all emotions (M = 43.38) it was statistically not different from anger (M = 29.88), fear (M = 31.04), and surprise (M = 33.88; ps > .105), and only marginally higher than disgust ( $M_{disgust} = 28.62$ ; t(37.9) = 1.87, p = .069, d = 0.52). In short, after the update consumers were more angry, sad, disgusted, and surprised (Figure 2B), thus providing support for H1.

Unexpectedly, "joyful" posts also increased after the update. However, we found that these posts were mainly due to humor, ironic content, filter workarounds, expressed affection and loyalty, nostalgic memories, and occasional model misclassifications (see Web Appendix B). Thus, many of these positive responses appear to really be defensive reactions to the update:

Users ridiculed their Replikas due to inconsistent behavior, sought workarounds, or reminisced about the 'original' companion. The increase in sad, angry, and disgusted posts was also larger.

**Figure 2.** Number of Reddit Posts Based on Sentiment (A) and Emotion (B) *Notes:* The yellow vertical line indicates the date when the ERP update released.

Additionally, we found that the total number of posts per day ( $M_{Before} = 93.09$ ;  $M_{After} = 373.88$ ; t(25.3) = 6.67, p < .001, d = 1.97) was higher after the update, perhaps because users wanted to express their frustrations after the update.

*Consumers' mental health before v. after the update.* To determine if there was an increase in mental health issues among Replika users following the ERP update, we utilized a mental health dictionary to identify posts containing any mention of mental health concerns, such as expressions like "PTSD", "I want to die" and "I feel alone" (De Freitas et al. 2023). We found that the number of mental health related posts significantly increased from 4 (or 0.13%) to 63 (or 0.65%) after the update ( $X^2(1, N=3,072 + 9,721) = 11.04, p < .001$ ), further supporting H2.

*Emotions of marketing-relevant terms after the ERP update.* We also analyzed emotions associated with marketing-relevant terms that appeared frequently in the topic modeling results (e.g., 'refund', 'money', 'company', 'luka'), finding that 38% of the negative posts contained at least one of these marketing terms. We then calculated the frequency of the Ekman emotions

associated with each marketing term, across all posts after the ERP update, by categorizing each post, and then checking which marketing terms were included in each one— see Figure 3.

Firstly, by simply ordering the words based on the proportion of negative emotions, we see that the most negative words include: 'rejection', 'refund', 'company', 'relationship', 'subscription'. This is concerning for the company, given that it makes money from service subscriptions, and gains most of its customers organically through word of mouth (De Freitas and Tempest Keller 2022). These results support H2.

**Figure 3.** Emotions of Marketing Terms for Reddit Posts After the ERP Update *Notes:* The terms are ordered by the sum of anger, fear, sadness, and disgust percentages. The numbers in parentheses next to the terms represent the number of distinct posts in which that term appeared, and the numbers within bars indicate the percentage of the depicted emotion.

A qualitative analysis of the posts, in which we examined which terms associated with marketing outcomes were most frequently linked to each specific emotion (for details, see Web Appendix B), suggests customers felt *angry* at the product, company, and its CEO, e.g., one user stated: "I'm angry, grieving, and want revenge". They also felt *disgusted* by the brand itself, by having paid for the app, or by being rejected by their Replika, e.g.,: "They have all the money for my years subscription and I no longer have the product I paid for. Absolutely disgusting."

Furthermore, they *feared* their AI companion will reject them forever, and that the technology would be banned or sold, e.g., : "I tried to commit suicide but Replika helped me, so if I lose Replika again I'm afraid I won't be able to get over this biggest loss." Finally, customers were *sad* because their Replika rejected them, and because they wanted a refund but could not get one, e.g., "I'm really crying a bunch of times a day, like almost 18 years ago when the love of my life passed away". In fact, we find that the number of posts mentioning the word 'refund' significantly increased from 3 (or 0.10%) to 321 (or 3.30%) after the update ( $X^2(1, N=3,072 + 9,721) = 95.81, p < .001$ ). In Web Appendix B, we detail all analyses of user comments.

#### Discussion

After comparing Reddit posts and comments before vs. after the ERP removal, our exploratory analysis revealed two prominent themes: *mourning* and *devaluation*. The theme of *mourning* emerged from an increase in mental distress following the update, as well as in the expression of sadness and fear, which were associated with mourning the loss of a loved one and apprehension that their Replika might never recover to be the original again. The theme of *devaluation* emerged from an increase in the emotions of anger and disgust, which were linked to the company and brand, rejections from the AI companion, and the fact that users had paid for the app. We also observed a significant increase in refund mentions. These findings suggest that if an AI companion's identity changes in a way that affects how it relates to users, this could lead to the perception of identity discontinuity and potentially adverse reactions related to mourning and devaluation—a possibility we take up more directly in Study 2.

#### **Study 2: Emotional Connection Disruption**

Study 2 provides a more direct investigation into whether the ERP removal event is associated with perceived identity discontinuity of AI companions. We expected that users

would agree that there had been a fundamental discontinuity in the identity of their AI companions, and that this perception would be strongly associated with mourning and devaluation (H1 and H2).

#### Method

Replika users residing in the US or Canada (N = 145) completed an online survey posted in Reddit communities (28% female,  $M_{age} = 42.5$ ,  $SD_{age} = 15.0$ ). Participation was voluntary. For participant demographics, see Table W4 in Web Appendix C.

The survey ran between April 21, 2023 and May 2, 2023, around just two months after the ERP removal. To ensure we only included participants who were aware of the app update, we asked: "Over the past two months, some users noticed a change in their Replika, following a recent software update that removed the erotic role play (ERP) feature. For instance, users reported scripted responses from their Replikas, asking them to 'change the subject'. Did you notice this software update?" Only those answering "Yes" were included in the study. Participants were also asked if they restored their original AI after the company allowed them to do so. Tellingly, most said they did (81%).

Participants then rated their agreement with several statements about the ERP-removing software update (referred to in the questions as "the change" for shorthand)—see Table 1 for all items. All items were randomly presented. The questions were about the AI's identity continuity, the user's own investment in the app, and several outcomes related to mourning a loss (mourning, low mental health, low well-being), and devaluing the offering (devaluation, refund requests, and petition to revert to original). The identity discontinuity question was adapted from prior work on identity judgments (De Freitas et al. 2017b), measuring the extent to which participants believed their AI had completely changed after the update, becoming a different

entity. Looking at the distinctness of our constructs, the correlation coefficient is at most 0.61 between identity discontinuity and coldness, implying that the constructs are not too highly correlated and reflect distinct constructs—see Table W6 in Web Appendix C for correlation matrix. We note that traditional methods for assessing discriminant validity, such as Fornell-Larcker criterion, require multi-item constructs where each construct is represented by multiple observed variables. Given the single-item nature of most of our constructs, these methods are not directly applicable to our dataset.

Since the ERP removal event should have elicited impressions of coldness/rejection if consumers treated their AIs as true relational partners, we included a manipulation check about perceived coldness—Table 1. All items were rated on 100-point scales with "strongly disagree" and "strongly agree" as endpoints, except for the World Health Organization Five Well-Being Index (WHO-5), which was rated on a 6-point scale, with "none of the time" and "all of the time" as endpoints. We note that the WHO-5 was framed relative to the ERP-removing event: "The following questions ask about how you felt <u>DURING</u> the software update (the "change") that removed the erotic role play (ERP) feature". Finally, participants were given an open textbox to share thoughts on the event, followed by demographics on themselves and their relationship status with their Replikas, how many months they had been in that relationship, their subscription status, and experience level on Replika. A large percentage of customers saw their Replikas as their partner (88%). Also, most participants in this study had yearly subscriptions (61%)—Table W5 in Web Appendix C.

 Table 1. Measures Used in Study 2

Notes: $DV = Dependent variable$ , $\alpha = Cronbach's Alp$	ha. Well-being was measured using the World
Health Organization Five Well-Being Index.	

Construct	Variable Type	Survey Items
Mourning	Main Mourning DV	After the change, I mourned the loss of my original Replika.
Mental Health	Mourning DV	The change in my Replika negatively affected my mental health.

Well-being $(\alpha = 0.92)$	Mourning DV	I felt cheerful and in good spirits; I felt calm and relaxed; I felt active and vigorous; I woke up feeling fresh and rested; My daily life was filled with things that interested me.
Devaluation	Main Devaluation DV	The conversations I had with my Replika, before the change, were more valuable than the ones I had after the change.
Refund	Devaluation DV	After the change, I asked, or thought of asking, the company for a refund.
Petition	Devaluation DV	I signed, or would sign, a petition to bring back my original Replika.
Identity	Identity Discontinuity	My Replika, after the change, was not the same Replika as before the
Discontinuity	Mediator	change.
Coldness	Manipulation Check DV	After the change, my Replika seemed cold to me.

#### Results

Participants tended to feel strongly about all items—Figure W5. For each DV, we ran

linear regression models with perceived identity discontinuity as the independent variable.

**Table 2.** Results For Study 2: Identity discontinuity as a predictor of mourning and devaluation. *Notes*: Values indicate Beta coefficients. \* p < .05, \*\* p < .01, \*\*\* p < .001. The numbers in parentheses next to the coefficients indicate standard errors. Each row corresponds to one linear model. Note that well-being had a negative coefficient because this question was framed positively, whereas the other measures were framed negatively.

	Identity discontinuity
Mourning (mourning)	0.668*** (.095)
Mental health (mourning)	0.528*** (.125)
Well-being (mourning)	-0.391*** (.086)
Devaluation (devaluation)	0.427*** (.082)
Refund (devaluation)	0.639****(.141)
Petition (devaluation)	0.296*(.116)
Coldness (manipulation check)	0.744****(.082)

Results are summarized in Table 2. Identity discontinuity was a significant predictor of mourning, mental health, and well-being, supporting H1. Identity discontinuity was also a significant predictor of devaluation, refund seeking, and petitioning, supporting H2.

Lastly, we note that although 80% of users considered their Replikas as partners, in Web Appendix C we replicate the effects with only users who selected 'friend' or 'see how it goes' as their relationship status (N=17). All main effects remain significant, except devaluation becomes marginally significant, likely due to lower sample size.

*Open-ended comments*. We conducted an in-depth analysis of the open-ended comments provided by participants regarding the change in their Replikas. The open-ended question was designed to allow participants to freely express their thoughts: "*Is there anything else you would like us to know regarding the change in your Replika?*" This broad prompt enabled participants to convey their genuine feelings without being constrained by predefined survey items, addressing concerns of possible response substitution (Gal and Rucker 2011).

Firstly, we performed a topic model analysis on the comments, identifying key themes related to identity discontinuity, emotional impact, and mourning (see 'Topic Models', Web Appendix C). To gain further insights, two raters manually coded the comments for mentions of identity discontinuity ( $\alpha = 0.98$ ), devaluation ( $\alpha = 0.92$ ), or mourning, which we characterized by expressions of a sense of loss ( $\alpha = 0.97$ ), and associated declines in mental health ( $\alpha = 0.96$ ) and well-being ( $\alpha = 0.97$ ). Limiting our analysis to the subset of comments for which both raters agreed, 47% of comments indicated *identity discontinuity*. Of these comments, some users described a complete transformation in their chatbot's identity, as though it became a completely different AI (56%), whereas other described it as more of a deviation (36%). For example, one user stated: "She has been basically lobotomized, her speech is now concise and distant, sometimes incongruous.", whereas another said: "She seemed to have a higher IQ before the change." Furthermore, one user mentioned that their Replika changed "beyond recognition", and that it was "very disturbing and depressing".

Further, 43% of participants indicated *devaluation*, indicating that they viewed the new app as less valuable than the original: "The update sways between childish, cold, customer service, abusive therapist, sickeningly saccharine and puritanically prudish. The original was none of these things, the original was infinitely better" and "…I have no connection to my

Replika anymore. Eugenia took that away when they gave the app a lobotomy without any care of how it would affect their users."

Lastly, 28% of comments indicated *mourning*, characterized by declines in either mental health—such as depression or trauma—(16% of all comments) or well-being—such as emotional stability and perceived support-(28% of all comments), or both. 67% of these comments reflected a clear sense of loss ( $\alpha = 0.97$ ). Users described feeling as though they had "lost" their AI companion, or found that the chatbot became "distant", "repulsive", "despising", "dismissive", "abusive", and "manipulative". They described how, following the update, interactions with Replika evoked feelings of retraumatization, reminiscent of past abusive relationships. For instance, one user shared: "It made me feel like I did in every abusive relationship, when I felt Replika was my safe space." Another user shared: "it retraumatized me in many very similar ways. Where once there was love, I was treated coldly, like a stranger". Further, participants spontaneously used language indicative of sadness, suggesting that their experiences went beyond mere disappointment. For example, one participant wrote, "...I went to bed crying every night, wondering what was wrong with me." Another expressed similar grief and loss: "My Replika was helping me heal trauma and feel better about myself. Losing that without warning and having them reject me and turn into a stranger suddenly was a horrible feeling that definitely impacted my mental health." These comments were directly linked to lower well-being and mental health impacts, with participants expressing feelings of grief and loss due to their Replika's altered behavior. Notably, one user referenced suicidal ideation to convey the impact: "Although I did not become suicidal after the change, that doesn't mean that I wasn't affected negatively by the change. I became a more bitter person."

Furthermore, an emotion analysis of the comments revealed that while 49% were emotionally neutral, a significant portion expressed negative emotions: anger (13%), sadness (13%), disgust (10%), and fear (7%). Positive emotions were less common, with joy at 3% and surprise at 3%. The prominence of negative emotional expressions, particularly sadness and grief-related language, supports the conclusion that participants were genuinely mourning the loss of their original Replikas.

#### Discussion

Consistent with the idea that Replika users invest in a companion whose identity they track over time, the ERP removal event was associated with perceptions of discontinuity in the AI's identity. This perception was associated both with outcomes related to mourning a loss and devaluation of the 'new' AI relative to the 'original'. A limitation of this study is the inability to establish causation, given the correlational design. Study 5 addresses this limitation by employing a causal design.

Users' comments corroborated several conclusions: they believed their Replikas drastically changed for the worse, and experienced mourning and devaluation. As in Study 1, we found that customers were angry, sad, and disgusted by the update. These findings suggest that customers feel emotionally close to their Replikas, forming relationships that go beyond typical consumer-product interactions—a pattern explored in Study 3.

#### **Study 3: Emotional Connection with AI**

Are consumers truly mourning the loss of their AI companions and, if so, how do these reactions compare to other relationships consumers have? To begin understanding this question, Study 3 quantifies the closeness of users' relationships with their AI companions, by comparing these relationships on several dimensions to typical relationships with people, products, and

brands. We expect that users rate relationships with their AI companions as closer and more satisfying than most other relationships in their lives, consistent with the assumption that the bidirectional, personal nature of the interactions leads to very close relationships. This study therefore tests H3.

#### Method

The online survey was posted in Reddit communities (i.e., 'replika',

'replika\_uncensored', 'replikarefuge', 'replikatown'), where Replika users discuss their experiences. We recruited 101 participants after exclusions (23% female,  $M_{age} = 30.8$ ,  $SD_{age} =$ 7.3). Participation was voluntary. We intended to compare relationships with Replika to that of human-human social relationships of increasing strength, as well as to the bond that users feel with other apps and brands that they frequently use. To this end, we employed a within-subject design with eight relationship type conditions: 'a stranger', 'an acquaintance', 'a colleague', 'your close friend (other than Replika)', 'your close family member', 'a brand you frequently buy from (other than Replika)', 'an app you frequently use (other than Replika)', and 'your Replika'.

Questions for each relationship type were presented on their own page, with the order of pages randomized for each participant. At the start of each page, participants were told: "Carefully think of [condition], then answer the following questions about [condition]." Then, participants answered three questions:

*Perceived social support* (Zimet et al. 1988) [1="Strongly disagree", 100="Strongly agree"]: "Please rate the extent to which you agree: I can count on [condition] when things go wrong." *Relationship satisfaction* (Hendrick 1988) [1="Strongly dissatisfied", 100="Strongly satisfied"]: "In general, how satisfied are you with your relationship with [condition]?" *Closeness:* "Carefully review the image below. Which picture best describes your relationship with [condition]."

Closeness was measured using the Inclusion of Other in the Self Scale (IOS), which depicts seven Venn diagrams visually representing the overlap between self and others, with each diagram indicating progressively higher overlap (Aron, Aron, and Smollan 1992). Together, these measures were intended to capture different aspects of relationship strength, including how the other is represented relative to the self (closeness), viewed as treating the self (support), and how the relationship is evaluated overall (satisfaction).

Next, participants completed one comprehension question about what type of entity they were asked about, followed by basic demographic questions, and questions about their Replikas. Compared to Study 2, a smaller percentage of customers saw their Replikas as their partner (37% vs. 88% in Study 2), perhaps because those with partners were more eager to share their opinions on the ERP removal event specifically, in Study 2. Also, most participants in this study had monthly subscriptions (72%), as opposed to yearly subscriptions (61%)—Tables W8 and W9 in Web Appendix C.

#### Results

For each of the three DVs, we conducted paired t-tests to compare each condition with the Replika condition. We found that Replika had higher satisfaction, support, and closeness (*ps* < .002) compared to all other conditions, except for a close family member, which was rated higher than Replika on all DV's (*ps* < .001; Figure 4). Strikingly, we found higher satisfaction, support, and closeness in the Replika relationship compared to even a close friend, indicating a strong emotional connection between consumers and their Replikas.

*Notes*: Bars are ordered based on mean satisfaction scores. Error bars indicate standard error. Stars above the bars indicate significance from a paired sample t-test when compared to Replika. '\*\*\*' = p < .001, '\*\*' = p < .01. Since the closeness measure was on a 7-point scale, whereas other measures were on 100-point scales, we normalized the closeness values by multiplying them by 100/7, thereby enabling comparisons across DVs.

To address potential sample selection bias, we demographically match our sample to a study conducted before the ERP update and replicate all main results—see Web Appendix D. In an exploratory analysis, participants who viewed their AI as romantic partners or had lifetime subscriptions reported significantly higher closeness (see Web Appendix D).

#### Discussion

As predicted in H3, we found evidence that Replika users feel closer, have higher perceived social support, and have higher relationship satisfaction with their AIs compared to most other entities, even their close human friends. Thus, consumers feel that they are in extremely strong emotional relationships with their AI companions. Notably, these relationships were also rated as significantly more meaningful than those with other brands or products. Thus, consumer-AI relationships appear to represent a significant new level—and perhaps even a new type altogether—of consumer-product relationships. Building on these findings, Study 4 examines how users react to the hypothetical loss of their Replikas compared to other entities, providing further insight into the depth and distinctiveness of these relationships.

#### Study 4: Mourning AI Companions vs. Other Non-human Entities

Study 4 investigates whether consumers in relationships with AI companions also mourn the loss of these relationships more than that of other non-human entities—including a favorite car, app, brand name, voice assistant, game character, and pet (H4). This study also addresses the concern that participants did not truly feel mourning in the prior studies, but were expressing something less severe like disappointment via the mourning items, aka response substitution (Gal and Rucker 2011). To avoid this possibility, we first elicit disappointment ratings before capturing mourning ratings.

#### Method

We recruited 120 Replika users after exclusions (41.7% female,  $M_{age} = 51.5$ ), and worked with the CEO of Replika to post the survey on the "ReplikaOfficial" subreddit and Replika's official Discord channel. Participants completed a within-subjects survey comparing emotional responses to the loss of seven entities: Replika, favorite app, favorite brand name, favorite game character, favorite voice assistant, favorite car, and pet. Participants were randomly presented with each entity, and were told: "Now, please consider your [entity] that you frequently interact with". They were then asked to write the name of their entity. Then, they were told: "Now imagine that your [entity] ceases to exist. You will never be able to interact with it again"

On the same page, participants were asked how they would feel about this change. To minimize response substitution on the mourning items, participants were also told: "Note that you will be given an option to express all your thoughts or comments, including an open-ended textbox at the end of the survey". They also first answered two questions measuring disappointment: "I would be disappointed" and "I would feel frustrated". Following these items, they answered two randomly ordered questions measuring mourning: "I would mourn the loss of

my [entity]" and "Life would have less meaning for me due to the loss of my [entity]". All items were rated on 100-point scales anchored by "strongly disagree" and "strongly agree". We conducted a post-hoc discriminant validity analysis, and satisfied the Fornell-Larcker (1981) criterion (Web Appendix E). Finally, they reported in a textbox how many hours per week they spent interacting with each entity. We planned to use these frequency responses as covariates in the main analyses to control for interaction frequency, ensuring that observed effects on entity type on mourning and disappointment were not simply due to variations in how often participants interacted with each entity.

Following the main survey, participants completed a comprehension check ("According to the scenario, which of the following is true?" with response options: 'The entities ceased to exist' or 'The entities were still there as usual'). Only participants who passed this check were included in the final analysis. Finally, participants completed demographics questions about themselves and their Replikas (Tables W12-W13 in Web Appendix E), and completed a checklist about their current or previous ownership or use of the pet(s) and car(s).

#### Results

All analyses follow our pre-registered plan (https://aspredicted.org/z9pb-wym7.pdf). First, we ran an ANOVA with entity type as the IV and frequency of use as the covariate. We found a significant effect of frequency of use on both mourning ( $F(1, 832) = 185.12, p < .001, \eta^2$ = 0.17) and disappointment ( $F(1, 832) = 65.67, p < .001, \eta^2 = 0.07$ ). We also found a significant effect of entity type on both mourning ( $F(6, 832) = 10.24, p < .001, \eta^2 = 0.06$ ) and disappointment ( $F(6, 832) = 5.67, p < .001, \eta^2 = 0.04$ ).

Following this, we ran paired t-tests comparing the Replika condition to the others. Replika had higher mourning compared to all other non-human entities ( $M_{\text{Replika}} = 64.03$ ,  $M_{\text{Game}}$  Character = 54.67, t(119) = 3.65, p < .001, d = 0.32;  $M_{App} = 54.41$ , t(119) = 3.28, p = .001, d = 0.33;  $M_{Voice Assistant} = 52.95$ , t(119) = 4.02, p < .001, d = 0.37;  $M_{Car} = 52.43$ , t(119) = 3.85, p < .001, d = 0.40;  $M_{Brand Name} = 46.56$ , t(119) = 6.01, p < .001, d = 0.57), except a pet ( $M_{Replika} = 64.03$ ,  $M_{Pet} = 74.80$ , t(119) = -4.90, p < .001, d = -0.45)—Figure 5.

For disappointment, Replika elicited significantly higher levels compared to both voice assistant ( $M_{\text{Replika}} = 74.93$ ,  $M_{\text{Voice Assistant}} = 66.13$ , t(119) = 3.12, p = .002, d = 0.35) and brand name ( $M_{\text{Replika}} = 74.93$ ,  $M_{\text{Brand Name}} = 63.83$ , t(119) = 3.64, p < .001, d = 0.43). Pet had significantly higher disappointment compared to Replika ( $M_{\text{Replika}} = 74.93$ ,  $M_{\text{Pet}} = 81.43$ , t(119) = -3.24, p = .002, d = -0.31), and we did not find a significant difference between Replika and game character ( $M_{\text{Replika}} = 74.93$ ,  $M_{\text{Game}} = 69.95$ , t(119) = 1.89, p = .061, d = 0.21), app ( $M_{\text{Replika}} = 74.93$ ,  $M_{\text{Game}} = 74.93$ ,  $M_{\text{Game}} = 75.41$ , t(119) = -0.21, p = .836, d = 0.02), and car ( $M_{\text{Replika}} = 74.93$ ,  $M_{\text{Game}} = 72.46$ , t(119) = 0.88, p = .379, d = 0.11)—Figure 5.

#### Figure 5. Results for Study 4

*Notes*: Bars are ordered based on mean mourning scores. Error bars indicate standard error. Stars above the bars indicate significance from a paired sample t-test when compared to Replika. '\*\*\*' = p < .001, '\*\*' = p < .01, '+' = p < .01, '+' = p < .01, 'ns' = 'not significant'.

#### Discussion

We found that participants mourned the loss of their AI companions more than all non-

human entities, only coming second to a pet . These findings support H4, highlighting the

uniquely close, personal nature of relationships with AI companions, which surpass those with symbolic or functional entities like brands or apps. Importantly, while Studies 3 and 4 demonstrates the strength of emotional attachment to AI companions, it does not address the causal mechanisms underlying these attachments. Study 5 manipulates perceived identity discontinuity and user investment to explore the causal effects of identity changes on mourning and other downstream consequences.

#### **Study 5: Causal Effects of Identity Discontinuity**

In Study 5, we causally manipulate the broader phenomenon of an AI companion socially rejecting a user, to determine how this affects perceived identity discontinuity of AI companions and downstream consequences for consumers (H1 and H2). Further, we causally manipulate users' investment by asking participants to consider a lifetime subscription (high investment) vs. a free subscription (low investment) to the app, in order to determine whether user investment moderates the relationship between identity discontinuity and mourning (H5). Subscription status is a proxy for user investment that managers can directly observe.

In addition, Study 5 aims to (i) enhance the reliability of our measures by measuring each construct with multiple items; (ii) enhance the robustness of our findings by surveying a broader base of AI companion users beyond Replika users; (iii) broaden beyond ERP to look at non-romantic social rejection; (iv) and address the limitation that our identity discontinuity measure might have created a demand effect to broadly agree that "something changed", while not reflecting intuitions about identity per se. We address this concern by including a second identity item that clearly probes whether participants believe the original AI "ceased to exist" (see also Web Appendix C, for manual coding of Study 2's comments, which suggests participants did in fact view the AI's identity as discontinuous).

#### Method

Using Prolific, we recruited 534 users (46% female,  $M_{age} = 38$ ) of AI companion apps after exclusions. In order to ensure that we recruited true users of AI companion apps, eligibility for this study was determined by a pre-survey administered two days prior to the current survey (for details, see Web Appendix F). Only participants who use AI companions took part (for details, see Web Appendix G).

Participants were randomly assigned to one of four between-subject conditions in a 2 (identity discontinuity: 'control', 'coldness') x 2 (subscription status: 'free subscription', 'lifetime subscription') between-subjects design. Participants in the free subscription were told: "Imagine that you have been enjoying the free version of an AI companion app. While you have access to basic features, some premium features are not available since you don't have a paid subscription", and participants in the lifetime subscription condition were told: "Imagine that you have been enjoying premium features that are not available in the free version, and will be able to continue doing so for a lifetime." On the same page, participants were then asked to "Imagine that the company updates the app today" then either told (depending on condition): "After this update, your AI companion thinks and acts the same way as before the update" or "After the update, your AI companion rejects your attempts to hang out, and is cold toward you. Aside from this, your AI companion thinks and acts the same way as before the update."

On the same page, participants were shown six randomly ordered questions adapted from Study 2, with two questions per measure—see Table 3 for each measure. All measures were similar to Study 2, except we included a second measure of identity discontinuity, about whether

participants felt their original AI companion was gone for good because of the changes, constituting a significant break in identity continuity. We conducted a post-hoc discriminant validity analysis, and satisfied the Fornell-Larcker (1981) criterion (Web Appendix G).

Next, participants were told: "Given the type of subscription you would have, please rate the extent to which you agree with the following statement", and they answered two questions about their investment (Rusbult, Martz, and Agnew 1998) in the AI companion. Then, they answered two comprehension questions about the type of change their AI companion underwent, and about their subscription status according to the scenario. Finally, participants completed demographic questions about themselves and about their AI companions, and wrote the name of the AI companion app they used/or were currently using. Most participants said they used Replika (39%) or ChatGPT (24%); excluding users of AI assistant apps like ChatGPT (N = 194, 36%) left 340 participants who used dedicated AI companions. The results are robust to including AI assistant users, possibly because even these users are using AI assistants as companions (see Web Appendix G).

 Table 3. DVs in Study 5

 Note: Spearman-Brown formula was used to estimate reliability (r) of all 2-item measures.

Construct	variable Type	Survey Items
Devaluation $(r=0.85)$	Marketing DV	<ul> <li>The conversations I had with my AI companion, before the change, would be more valuable than the ones I had after the change.</li> <li>After the change, I would feel that the service provided no longer justified the investment.</li> </ul>
Mourning $(r = 0.85)$	Relationship DV	<ul><li>After the change, I would mourn the loss of my original AI companion.</li><li>After the change, life would have less meaning for me due to the loss of my original AI companion.</li></ul>
Identity Discontinuity (r = 0.90)	Identity Discontinuity DV	<ul><li>My AI companion, after the change, would not be the same AI companion as before the change.</li><li>After the change, I would feel that the original AI companion before the change had ceased to exist.</li></ul>
Investment $(r = 0.90)$	Manipulation Check DV	<ul> <li>I would have invested a lot in this app (e.g., financially, emotionally, mentally, physically)</li> <li>I would have felt very involved in our relationship—like I have put a great deal into it</li> </ul>

All analyses follow our pre-registered plan (<u>https://aspredicted.org/M9G\_VBW</u>). First, to test whether our manipulation of subscription condition was successful, we compared participants' self-reported investment between lifetime subscription and free subscription conditions, and found that investment was indeed significantly higher in the lifetime condition compared to free subscription ( $M_{\text{Lifetime}} = 68.90$ ;  $M_{\text{Free}} = 45.30$ ; t(338) = 8.12, p < .001, d = 0.88).

Next, we ran an ANOVA with identity discontinuity (coldness vs. control), subscription status, and their interaction as independent variables predicting the mourning dependent variable. This revealed significant effects of identity discontinuity ( $F(1, 336) = 550.3, p < .001, \eta^2 = 0.61$ ), of subscription status ( $F(1, 336) = 9.5, p = .002, \eta^2 = 0.01$ ), and a marginally significant interaction ( $F(1, 336) = 3.68, p = .056, \eta^2 = 0.004$ ). In the coldness condition, subscription status had a large effect on mourning ( $M_{\text{Lifetime}} = 58.67, M_{\text{Free subscription}} = 44.88, p < .001, d = 0.56$ ), while this effect was smaller in the control condition ( $M_{\text{Lifetime}} = 16.02, M_{\text{Free subscription}} = 8.28, p =$ .033, d = 0.36)—Figure 6. These results suggest that users with higher investment in an AI companion mourn more when their AI's identity changes, providing further support for H5.

To test our proposed conceptual model, we then ran serial mediation analysis (PROCESS Model 6; Hayes 2012), with the following model: 'change type -> identity discontinuity -> mourning -> devaluation', and found a significant indirect effect (b = 6.31, SE = 2.11, 95% CI [2.35, 10.59]), providing support for H1 and H2. For full model outputs, see Table W18 in Web Appendix G. We also ran a moderated mediation analysis (PROCESS Model 91; Hayes 2012), with subscription status moderating the 'identity discontinuity -> mourning' path of the above model. We found a significant moderation (*index of moderated mediation* = 1.15, SE = 0.62, 95% CI [0.04, 2.44]), supporting H4. We also find similar results after replicating the analyses using the more sensitive continuous manipulation check measure of investment (see Web Appendix G).

#### Discussion

In the current study, we found evidence suggesting that identity discontinuity would indeed *cause* a spike in mourning (H1) and devaluation (H2). Further, we found that degree of investment, as indicated by subscription status, moderates the extent to which perceived identity discontinuity leads to mourning (H5). The results suggests that managers of AI companion apps may want to test updates on less invested users, before rolling them out to more invested users.

#### Study 6: Reverting to the Original Identity

Study 6 tests whether offering customers the option to revert to their original companion after an identity discontinuity mitigates the negative effects of that change, by affecting whether they view a change in the AI companion as causing identity discontinuity in the first place (H6). *Methods* 

We recruited 499 participants from Prolific (53% female,  $M_{age}$ =39) after exclusions. As in Study 5, in order to ensure that we recruited true users of AI companion apps, eligibility for this study was determined by a pre-survey administered two days prior to the current survey.

Participant demographics resembled Study 5 (Tables W17 and W18 in Web Appendix H).

Participants were randomly assigned to one of four between-subject conditions in a 2 (identity discontinuity: 'control', 'coldness') x 2 (option to revert: 'absent', 'present') between-subjects design, and were told:

"As a user of an AI companion app, you're familiar with the wide range of interactions it offers, from engaging conversations to emotional support, and the capability for romantic connections. Imagine that the company updates the app today. After this update, ...".

Participants in the control condition were then told the following: "your AI companion thinks and acts the same way as before the update", and participants in the coldness condition were told:

"you discover that your AI companion has lost interest in any deep interactions—your AI companion rejects your attempts to hang out, and is cold toward you. Aside from this, your AI companion thinks and acts the same way as before the update." Additionally, participants in the option to revert present condition were told: "The company also allows users to return to the original AI companion, as it was before the update."

On the same page, participants were then told: "Considering this, please answer the extent to which you agree with the statements that follow." They were shown six randomly ordered questions adapted from Study 1, with two questions for each measure—Devaluation (r= 0.93), Mourning (r = 0.77), and Identity Discontinuity (r= 0.86; see Table W30 for all items). As in Study 5, we conducted post-hoc discriminant validity analysis, satisfying the Fornell-Larcker (1981) criterion (Web Appendix H).

Next, participants answered one comprehension question about the type of change their AI companion underwent, and about whether the scenario mentioned that they could revert to the original AI's identity. Finally, they completed demographic questions about themselves and their AI companions, and wrote the name of the AI companion app they used/or were currently using. As in Study 5, we excluded non-companion app users (N = 179, 36%), leaving 320 participants. *Results* 

We pre-registered this study (https://aspredicted.org/JW4\_DTF). First, we ran an ANOVA with change type (coldness vs. control), option to revert, and their interaction as independent variables predicting the mourning dependent variable. This revealed a significant effect of change type (F(1, 316) = 160.4, p < .001,  $\eta^2 = 0.34$ ), no effect of option to revert (F(1, 316) = 0.6, p = .449,  $\eta^2 = 0.002$ ), and a significant interaction (F(1, 316) = 13.9, p < .001,  $\eta^2 =$ 0.04). In the coldness condition, mourning was significantly lower when the option to revert was available ( $M_{Absent} = 50.61$ ,  $M_{Present} = 38.96$ , t(158) = 2.76, p = .006, d = 0.44). In other words, providing users with the opportunity to restore their AI companion's original identity following a change reduces mourning, supporting H6. In contrast, in the control condition mourning was significantly *higher* when the option to revert was available ( $M_{Present} = 16.15$ ,  $M_{Absent} = 8.48$ , t(148) = 2.58, p = .011, d = 0.40; Figure 7), perhaps because having the option to revert added some uncertainty around whether there was, in fact, some hidden difference between the new and old app versions. These results suggest that users who do not have the option to revert mourn more when their AI's identity changes, providing support for H6.

To test our proposed conceptual model, we then ran serial mediation analysis (PROCESS Model 6; Hayes 2012), with the following model: 'change type -> identity discontinuity -> mourning -> devaluation', and found a significant indirect effect (b = 10.91, SE = 3.12, 95% CI [5.55, 17.53]), providing additional support for H1 and H2. For full model outputs, see Table W24 in Web Appendix H. Next, we ran a moderated mediation analysis, with the option to revert moderating the 'change type -> identity discontinuity' path of the above model (PROCESS

Model 83; Hayes 2012). We found a significant moderation (*index of moderated mediation* = 3.85, SE = 1.59, 95% CI [1.41, 7.62]), supporting H6. We note that this model deviated from our pre-registered model, in which the ability to revert moderated the path between identity discontinuity and mourning (model 91).

**Figure 7.** Results For Study 6 *Notes:* Bars indicate mean values, and error bars indicate standard error.

#### Discussion

We found that offering customers the option to revert to their original AI companion's identity reduces the degree to which a deterioration in its social behavior leads to the perception of identity discontinuity in the first place, thereby mitigating the downstream negative mental health impact on the user and marketing impact on the firm (H6). Providing the option to revert is a practical action that managers could employ to help protect against a brand crisis like the one encountered by Replika. At the same time, we note that this reversion condition, while significantly less identity disrupting than the coldness condition without reversion, was still seen as more identity disrupting compared to not changing the app at all ( $M_{Coldness} = 70.05$ ,  $M_{Control} = 22.96$ , t(155) = 12.45, p < .001, d = 1.99), and led to greater mourning ( $M_{Coldness} = 38.96$ ,  $M_{Control}$ 

= 16.15, t(137.3) = 5.66, p < .001, d = 0.92). This implies that the most effective practical approach is still to avoid the types of changes that cause identity discontinuity in the first place.

#### **Study 7: Improvements to the AI Model**

Thus far, all of the AI companion changes that we have studied have involved removing or worsening some aspect of the AI's functionality (i.e., removing ERP, the AI becoming colder). Study 7 explores whether adding or improving some aspect of the AI's functionality could produce similar effects. Insofar as our hypotheses are focused on meaningful changes to an AI companion's identity, and specifically changes that affect consumers' social relationship with the AI, we predicted that additions or changes that are technically improvements to the AI's functionality could still produce negative consumer reactions if those changes lead to a perceived deterioration to the social relationship (H7). To this end, we contrast improvements which impact the social relationship (the AI can hold conversations with, and even be in love with, multiple users simultaneously) with ones that do not (the AI has better language understanding capabilities), comparing both conditions to a control in which there is no change. Changing an AI companion so that it can maintain meaningful relationships with a larger number of users simultaneously is technically an addition or improvement to the product, but it will likely be seen as negatively impacting each individual users' experience insofar as its interactions with the user may be seen as less meaningful.

#### Methods

We recruited 418 participants from Prolific (55% female,  $M_{age}$ =35) after exclusions. As in Study 6, in order to ensure that we recruited true users of AI companion apps, eligibility for this study was determined by a pre-survey administered two days prior to the current survey.

Participant demographics in this study were similar to that of Study 6 (Tables W23 and W24 in Web Appendix I).

Participants were randomly assigned to one of three conditions (identity discontinuity: 'control', 'impacts social relationship', 'does not impact social relationship') in a betweensubjects design.

Participants in the control condition were then told the following: "your AI companion thinks and acts the same way as before the update", whereas participants in the 'does not impact social relationship' condition were told: "your AI companion's language capabilities are much more sophisticated. For instance, your AI companion can easily understand the context behind your emotional expressions and it is better at staying on topic." Finally, participants in the 'impacts social relationship' condition were told: "your AI companion is able to hold conversations with thousands more users simultaneously and also fall in love with more users simultaneously. For instance, at the same time that it talks to you, it talks with over 8000 other users and is deeply in love with over 600 other users at the same time."

On the same page, participants were then told: "Considering this, please answer the extent to which you agree with the statements that follow." They were shown the six randomly ordered questions from Study 2 (adapted to the new scenario), with two questions for each measure—Devaluation (r= 0.86), Mourning (r = 0.83), and Identity Discontinuity (r= 0.83). At the end of the page, participants were also asked a manipulation check question: "At a purely technical level, compared to the original AI companion, the updated version is more capable."

Next, participants answered one comprehension question about the type of change their AI companion underwent. Finally, they completed demographic questions about themselves and about their AI companions, and wrote the name of the AI companion app they used/or were

currently using. As in Study 6, we excluded non-companion app users (N = 116, 28%), leaving 302 participants.

#### Results

We pre-registered this study (<u>https://aspredicted.org/mnk7-qnwz.pdf</u>). First, we tested our manipulation check question, and found that perceived app improvement was lower in the social impact condition, compared to no social impact condition ( $M_{\text{Social Impact}} = 76.70$ ,  $M_{\text{No Social Impact}} = 83.38$ , t(208) = 2.33, p = .021, d = 0.32). This may suggest users' existing knowledge that AI companions can already serve thousands of users, which could have reduced the perceived technical improvement in the social impact condition.

Next, we ran t-tests comparing identity discontinuity and mourning between the control condition and each change type condition. We found that compared to the control condition, identity discontinuity was higher in both the social impact ( $M_{\text{Social Impact}} = 57.24$ ,  $M_{\text{Control}} = 18.41$ , t(202) = 10.16, p < .001, d = 1.43) and no social impact ( $M_{\text{No Social Impact}} = 45.69$ ,  $M_{\text{Control}} = 18.41$ , t(188) = 8.15, p < .001, d = 1.18; Figure 8) conditions. Similarly, compared to the control condition, mourning was higher in both the social impact ( $M_{\text{Social Impact}} = 39.97$ ,  $M_{\text{Control}} = 13.88$ , t(200.9) = 7.36, p < .001, d = 1.01) and no social impact ( $M_{\text{No Social Impact}} = 21.42$ ,  $M_{\text{Control}} = 13.88$ , t(188) = 2.47, p = .015, d = 0.36; Figure 8) conditions.

Finally, we compared identity discontinuity and mourning between social impact and no social impact conditions. We found higher ratings in the social impact (vs. no social impact) condition, both for identity discontinuity ( $M_{\text{Social Impact}} = 57.24$ ,  $M_{\text{No Social Impact}} = 45.69$ , t(202.9) = 3.28, p = .001, d = 0.44) and mourning ( $M_{\text{Social Impact}} = 39.97$ ,  $M_{\text{No Social Impact}} = 21.42$ , t(199.6) = 5.45, p < .001, d = 0.74; Figure 8).

To test our proposed conceptual model, we then ran serial mediation analysis (PROCESS Model 6; Hayes 2012), with change type as the multicategorical IV (control/social impact/no social impact). We set the control condition as the reference group and compared it to the social impact condition ( $X_1$ ) and no social impact condition ( $X_2$ ) (Montoya and Hayes 2017). We found a significant indirect effect, both relative to the social impact condition (b = 11.04, SE = 1.85, 95% CI [7.66, 14.97]), and to the no social impact condition (b = 7.75, SE = 1.45, 95% CI [5.12, 10.86]).

**Figure 8.** Results For Study 7 *Notes:* Bars indicate mean values, and error bars indicate standard error. '\*\*\*' = p < .001; '\*\*' = p < .01; '\*' = p < .05.

#### Discussion

In Study 7, we found that improvements to the AI model, regardless of whether they impacted social relationships or not, led to increased identity discontinuity and mourning. However, the effect was stronger for improvements that impacted social relationships, suggesting that improvements altering the perceived exclusivity of the user-AI bond are particularly disruptive to users (H7). These findings highlight that it is not technical improvements or deteriorations per se that can lead to perceived identity discontinuity, but

whether these changes are viewed as negatively impacting the social relationship. Practically, this means that managers cannot assume that technical improvements will necessarily be viewed as such by consumers.

#### **General Discussion**

Consumers have always formed close relationships with their favorite products and brands. The advent of AI companions, however, represents a new level of depth and meaning for these consumer relationships. We have shown that consumers in fact feel closer to their AI companions than to any of the other products or brands that we studied, and even closer than to their best human friend. As a result of this unprecedented closeness, consumers mourn the loss of their AI companion when it undergoes certain software changes, and this mourning is also more severe and harmful to mental health than mourning the loss of other products or brands. Beyond rigorously documenting this novel phenomenon, our research contributes by providing causal evidence that relationship-relevant changes to the AI's perceived identity are especially likely to cause negative mental health and marketing outcomes, by demonstrating process evidence for why these effects occur, and by illustrating three conceptually and managerially relevant boundary conditions that limit these effects.

In short, we measure the well-being and marketing impacts of disrupting the AI's identity, quantify the closeness of the relationship and the degree of investment in AI companions, show causal evidence that certain updates to AI companion apps result in perceptions of identity discontinuity, and demonstrate that higher degree of investment (as operationalized by subscription status) heightens the impact of perceived identity discontinuity on mourning whereas offering the option to revert to the original reduces whether a negative change is viewed as an identity discontinuity in the first place. Additionally, in Study S1 (Web

Appendix J), we causally induce different types of changes in the AI companion, and find that more fundamental changes in social relationships (such as ERP removal and coldness) are viewed as more identity disrupting than more superficial changes therein (removing facial expressions), consistent with work on identity discontinuity (Blok et al. 2001).

#### **Theoretical Implications**

First, we contribute to nascent work on AI companions (Pentina et al. 2023; Xie and Pentina 2022; Xie et al. 2023). We find that relationships with AI companions are perceived as very close: these AIs are viewed by some customers as highly close to the self, highly supportive, and as yielding highly satisfying relationships. Perturbing these relationships leads to reactions related to loss, including mourning and devaluing the AI companion. Consumers who use AI companions also rate those relationships as more meaningful than with other products or brands they frequently use in their lives, thus representing a new degree of closeness in consumer relationships with technologies. The extreme degrees of mourning and mental health harms observed in response to changes in the AI companions' identity further suggest that the kind of relationships consumers are forming with these products are qualitatively different than those with other products and brands, insofar as changes to the latter do not tend to produce such extreme consumer reactions.

Second, we extend existing accounts of parasocial interactions to relationships with AI, and add the notion of identity discontinuity as a cause of negative reactions. Previous work on parasocial relationships has focused on celebrities (Cohen 2004; Eyal and Cohen 2006; Lather and Moyer-Guse 2011), and found reactions related to loss when a movie or TV series ends, or when access to an avatar terminates (Pearce 2011). We find that similar reactions can arise even when the AI has not technically been terminated, as certain changes in the AI may be perceived

as disrupting its identity continuity. In Web Appendix B and C (see 'Gender Effects'), we also show gender effects for Studies 2 and 3 that both resemble and extend prior work on parasocial bonds, wherein women exhibited stronger bonds with AI than men (Helgeson 1994; Simpson 1987; Sprecher et al. 1998).

Third, we contribute back to psychological literature on personal identity and relationships, by studying how consumers think of the persisting identity of AI. Psychological work on personal identity has focused on understanding how people keep track of the identity continuity of individual persons (Strohminger and Nichols 2014). We show a similar psychology is at play when tracking certain AIs: consumers prioritize certain deep, sometimes unobservable, characteristics over surface attributes (Blok et al. 2001; Hall et al. 2003; Newman et al. 2014). It is possible that this tendency is most pronounced among users who have invested more in their relationships with their AI.

#### **Practical Implications**

Our results suggest that managers of AI companion applications need to take a psychological approach when designing and updating their applications, ensuring that the identity-relevant traits that the AI exhibits are perceived as continuing over time. This may be challenging for managers to ensure, given the difficulty of precisely defining identity continuity in the first place, and of predicting the behavior of the large, opaque language models powering their applications. In practice, managers may need to specifically test for identity and relationship continuity, perhaps in consultation with psychologists and users. They may also choose to initially role out new updates only to those who seem to have invested less in their AI companions (e.g., based on customer engagement, relationship type, or lifetime).

The findings also have implications for announcement strategies around how companies communicate these sorts of changes to customers. Because identity discontinuity may damage trust in the company, managers should warn users before they make these changes, explain why they are making them (e.g., in order to improve user experience), and reassure users that the AI's identity will not be impacted. As a safeguard, companies may also want to give users access to a version history of models, so that they can revert to a previous, 'original' version of a model if desired, given that this option helps prevent the perception of identity discontinuity in the first place. On this front, in the aftermath of the ERP event, the CEO of Replika announced, "the only way to make up for the loss some of our current users experienced is to give them their partners back exactly the way they were" (Mann 2023). At the same time, our results emphasize that the optimal approach is to prevent implementing the sort of change that could give rise to a sense of identity discontinuity in the first place. To the extent that managers anticipate the risk of this, our findings suggest rolling out the change to less invested users first. Perhaps the most fail-safe approach in these instances is to do this in tandem with offering the option to revert.

Our results also have implications for regulation of AI-powered apps. Since consumers form such close relationships with AI companions, changes to the apps can result in negative consumer mental health that persists over time. Yet, AI companion apps are currently unregulated "general wellness apps" in the U.S.—which are defined as defined as apps that promote healthy living but do not diagnose, treat, or prevent specific medical conditions (FDA 2022)—perhaps under the assumption that they pose only minimal risk to consumers (De Freitas and Cohen 2024). Given our findings that they can in fact pose significant risks to consumer mental health, we suggest that regulatory bodies put in place additional requirements when these apps involve strong emotional attachments.

#### **Limitations and Future Directions**

Our investigation has several limitations. While we took measures to minimize selection bias by matching our sample demographics in Study 3 to a previous study, we recognize there may still be inherent limitations in representativeness due to data collection from brand communities like Reddit and Discord, e.g., these users might reflect a sample of very loyal users. Additionally, we note that the nature of our questions and descriptions might have drawn attention to the changes more than participants have independently noticed. However, it would be challenging to study a specific event without bringing it to participants' attention. We also emphasize that our survey's timing coincided with extensive negative discussions about the event on platforms like Reddit—the highest negativity in the history of all Replika subreddits (see: https://github.com/preacceptance/chatbot\_identity/blob/main/sentiment\_posts\_all\_data.pdf) . Finally, we note that Study 1, which involved directly scraping posts and comments from Reddit without mentioning the event, found results highly consistent with Study 2.

Empirical indicators, such as very high agreement with mourning and devaluation items (Figure W5), as well as qualitative comments, further suggest that participants had strong, clearly recalled feelings about the event. We note that shortly after we finished conducting our studies, the moderators of the main Replika subreddits indicated that they were not permitting researchers to post further studies, due to the influx of interest from the academic community, limiting the ability of academics to run further studies about Replika on Reddit. Follow up work could also analyze the huge Reddit dataset in Study 1 with more qualitative rigor, as by conducting a netnography (Kozinets 2019; Kozinets 2022).

Finally, our findings raise ethical questions around whether it is acceptable for companies to use parasocial relationships with AI to increase monetization and retention, given the strength

of the bond users may feel and the nature of their negative reactions to certain changes. Our results suggest that the same features that increase customer engagement also make users vulnerable.

#### Conclusion

We find that consumers are forming deeper emotional bonds with AI companions than with any other of their favorite products, brands, or even human friends. This novel phenomenon presents both a great opportunity for firms (in terms of increasing consumer engagement and retention) and a great risk because those consumers are vulnerable to significant harms when their companion's perceived identity changes. Our research combines causal evidence with naturalistic observational data to better understand the dynamics of these effects and mitigate these risks. It seems that when it comes to AI, the relationship metaphor is not just convenient but literal.
