Abstract. The Zee-Babu model is an economical framework for neutrino mass generation as two-loop quantum corrections. In this work, we present a UV completion of this model by embedding it into an $SU(5)$ unified framework. Interestingly, we find that loop-induced contributions to neutrino masses arising from colored scalars are just as important as those from color-neutral ones. These new states, which are required from gauge coupling unification and neutrino oscillation data to have masses below $\mathcal{O}(10^3)$ TeV, may be accessible to future collider experiments. Additionally, the model can be probed in proton decay searches. Our Markov chain Monte Carlo analysis of model parameters shows a high likelihood of observable $p \rightarrow e^+ \pi^0$ decay signal in the first decade of Hyper-Kamiokande operation. The model predicts a vector-like down-type quark at the TeV scale, utilized for realistic fermion mass generation and gauge coupling unification. The model is UV-complete in the sense that it is a unified theory which is realistic and asymptotically free that can be extrapolated to the Planck scale.

1 Introduction

The origin of neutrino masses needed to explain a variety of neutrino oscillation experiments remains a mystery today and is a subject of intense experimental and theoretical scrutiny. New physics that go beyond the Standard Model (SM) is required to explain the oscillation data, but the nature of such new physics is completely unknown. A deeper understanding of its origin could have a profound impact on the evolution of the Universe and may also reveal new symmetries and conservation laws. The seesaw mechanism, which introduces gauge singlet fermions to the SM can elegantly explain the smallness of neutrino masses [1–5]; however, the scale of new physics is typically close to the grand unification scale, which cannot be directly tested. This comment also holds true when gauge non-singlet scalars ($SU(2)_L$ triplets in type-II seesaw [6–8]) or fermions ($SU(2)_L$ triplets in type-III seesaw [9]) are introduced to generate small neutrino masses.

An alternative to the high-scale seesaw is the radiative neutrino mass generation mechanism, wherein neutrino mass is zero at tree-level, but is induced via quantum corrections [10–14] (for reviews, see [15, 16]). The smallness of neutrino mass in this context arises from loop and chiral suppression factors, and not from the inverse proportionality to a high scale of new physics. In fact, many realizations of the radiative mechanism require the new physics scale to be close to a TeV, with the potential to be directly tested in collider experiments as well as in flavor observables.

The goal of this paper is to present an ultraviolet (UV) completion of a simple radiative neutrino mass model, the Zee-Babu model [13, 14], by embedding the model into a grand unified theory (GUT) framework [17–22] based on the Georgi-Glashow $SU(5)$ gauge symmetry [19]. Such an embedding would be more satisfying and complete, since the new particles needed for neutrino mass generation would belong to complete multiplets of the GUT symmetry group. Furthermore, the UV-completion we present here is fully realistic, leading to an asymptotically

free theory that can be extrapolated all the way to the Planck scale. This includes compatibility with gauge coupling unification, which is problematic in the Georgi-Glashow $SU(5)$ theory [19], as well as with realistic fermion mass generation, which is also an issue in the original $SU(5)$ theory. The unified model presented here is testable in proton decay search experiments, with our Markov chain Monte Carlo analysis showing a strong likelihood of observing the decay $p \rightarrow e^+\pi^0$ in the first decade of operation of the Hyper-Kamiokande experiment [23]. The model is also testable at colliders through its predictions of a third-family vector-like quark (VLQ), as well as new charged and colored scalars with masses in the TeV–multi-TeV range.

The Zee-Babu model [13, 14] extends the SM with two new scalars, $\eta^+(1, 1, 1)$ and $k^{++}(1, 1, 2)$, with $SU(3)_C \times SU(2)_L \times U(1)_Y$ quantum numbers as indicated. Their Yukawa couplings, $f_{ij}L_iL_j\eta^+ + g_{ij}e_i^c e_j^c k^{--}$, with $f_{ij} = -f_{ji}$ and $g_{ij} = g_{ji}$ (i, j are family indices here), as well as a cubic scalar coupling $\mu(\eta^+\eta^+k^{--})$ jointly break lepton number by two units, and would generate neutrino Majorana masses via two-loop diagrams involving the exchange of these scalar fields. An $SU(5)$ embedding of these fields can be realized by the addition of a 10_H and a 50_H to the scalar sector of minimal $SU(5)$ with antisymmetric 10_H and symmetric 50_H Yukawa coupling matrices, which is what our framework adopts. Note the model has no right-handed neutrino ν_R , which goes well with $SU(5)$ unification, which also has no ν_R . The mass relations $m_b^0/m_\tau^0 = m_s^0/m_\mu^0 = m_d^0/m_e^0 = 1$ among the quarks and leptons predicted by the minimal $SU(5)$ model (the superscripts 0 indicate GUT scale values of the masses), while a good order of magnitude estimate, fail in detail when compared to experimental values by more than 100%. These relations can be corrected by introducing a vector-like pair of fermions in the $5 + \bar{5}$ representation [24]. Gauge coupling unification is realized in this framework consistently, see Fig. 3, by choosing the mass scales of certain particles to be below the GUT scale, as listed in Table 2. A key outcome of our analysis is that, in addition to the original diagrams mediated by η^+ and k^{++} scalars, neutrinos gain mass through diagrams mediated by their color-triplet and color-sextet counterparts [25–27], see Fig. 1. Once the experimental limits from proton decay are combined with gauge coupling unification constraints and perturbativity of Yukawa couplings, we find that both the color-neutral and the colored Zee-Babu states should have masses below $\mathcal{O}(10^3)$ TeV, which can potentially be discovered in future collider experiments, thereby testing the proposed model.

Neutrino mass generation in the framework of $SU(5)$ unification has been studied in conjunction with gauge coupling unification by various authors. Ref. [28] has studied type-II seesaw embedding in $SU(5)$, while Ref. [29] has proposed type-III seesaw embedding. Models of radiative neutrino masses [15, 16] have also been embedded in $SU(5)$. The original Zee model [10], where the neutrino masses arise as one-loop radiative corrections, has been embedded in $SU(5)$ in Ref. [30–32]. For the embedding of other loop-induced neutrino mass models in $SU(5)$, see for example, Ref. [33–41]. To our knowledge the model presented here is the first attempt to embed the Zee-Babu model within $SU(5)$.

This article is organized in the following way. In Sec. 2, we introduce the proposed embedding of the Zee-Babu model in $SU(5)$. In-depth discussions on correcting the wrong mass relations for the charged fermions, computation of the new physics contributions to flavor violating processes, and the generation of neutrino masses are provided in Sec. 3. Perturbativity of the Yukawa couplings is examined in Sec. 4. A detailed gauge coupling unification study, along

with proton lifetime analysis, is carried out in Sec. 5. Finally, we conclude in Sec. 6.

2 Embedding the Zee-Babu model in $SU(5)$

The model we propose extends the Georgi–Glashow $SU(5)$ model with a $10_H + 50_H$ scalar fields and a pair of $5_F + \bar{5}_F$ vector-like fermions. The scalars introduced are essential for generating neutrino masses through the Zee-Babu diagrams, while the vector-like fermion pair is crucial in correcting the wrong mass relations among the charged leptons and the down-type quarks [24]. Together, these particles will also enable realizing consistent gauge coupling unification.

Scalar sector:– The decomposition of the scalar fields in the theory under the SM gauge group, $SU(3)_C \times SU(2)_L \times U(1)_Y$, is shown below.

$$5_H = \phi_1(1, 2, 1/2) + \phi_2(3, 1, -1/3), \quad (2.1)$$

$$24_H = \Phi_1(1, 1, 0) + \Phi_2(1, 3, 0) + \Phi_3(8, 1, 0) + \Phi_4(3, 2, -5/6) + \Phi_4^*(\bar{3}, 2, 5/6), \quad (2.2)$$

$$10_H = \eta_1(1, 1, 1) + \eta_2(\bar{3}, 1, -2/3) + \eta_3(3, 2, \frac{1}{6}), \quad (2.3)$$

$$50_H = \chi_1(1, 1, -2) + \chi_2(3, 1, -\frac{1}{3}) + \chi_3(\bar{3}, 2, -\frac{7}{6}) + \chi_4(6, 1, \frac{4}{3}) + \chi_5(\bar{6}, 3, -\frac{1}{3}) + \chi_6(8, 2, \frac{1}{2}). \quad (2.4)$$

Note that here we denote the original Zee-Babu scalar fields η^+ and k^{--} as η_1 and χ_1 respectively, for uniformity of notation. Among these scalars, only neutral components of the Higgs fields in the adjoint and the fundamental representations acquire vacuum expectation values (VEVs) that break the GUT and the electroweak (EW) symmetries, respectively:

$$SU(5) \xrightarrow{\langle 24_H \rangle} SU(3)_C \times SU(2)_L \times U(1)_Y \quad (2.5)$$

$$\xrightarrow{\langle 5_H \rangle} SU(3)_C \times U(1)_{\text{em}}. \quad (2.6)$$

The VEVs of these fields are denoted as:

$$\langle 24_H \rangle = v_{24} \text{diag.}(2, 2, 2, -3, -3), \quad (2.7)$$

$$\langle 5_H \rangle = (0 \ 0 \ 0 \ 0 \ v_5)^T, \quad (2.8)$$

with $v_5 \simeq 174$ GeV. The nearly degenerate masses of the superheavy gauge boson, $X_\mu^{\pm 4/3}$ and $Y_\mu^{\pm 1/3}$ are given by $M_{X,Y} = 5\sqrt{2}g_{\text{GUT}}v_{24}$ (see, for example, Ref. [42]), where g_{GUT} represents the unified $SU(5)$ gauge coupling.

Once the GUT symmetry is broken, the submultiplets of the scalar fields will receive non-degenerate masses. Although there is no mass relations among the submultiplets of 5_H , 24_H , and 10_H , there exist three relations within the components of 50_H [35, 43], which read

$$m_{\chi_4}^2 = 3m_{\chi_2}^2 - 2m_{\chi_3}^2, \quad (2.9)$$

$$m_{\chi_5}^2 = 2m_{\chi_3}^2 - m_{\chi_1}^2, \quad (2.10)$$

$$m_{\chi_6}^2 = \frac{3}{2}m_{\chi_2}^2 - \frac{1}{2}m_{\chi_1}^2. \quad (2.11)$$

These mass relations will play crucial role in gauge coupling unification, which we discuss in Sec. 5.

Fermion sector:– As noted before, apart from three families of $\bar{5}_F$ and 10_F dimensional fermionic representations, the theory contains one pair of $5_F + \bar{5}_F$ vector-like fermions. These are parametrized as

$$\bar{5}_F^a = \begin{pmatrix} d_r^c \\ d_g^c \\ d_b^c \\ e \\ -\nu \end{pmatrix}_a, \quad 5_F = \begin{pmatrix} d_r \\ d_g \\ d_b \\ e^c \\ -\nu^c \end{pmatrix}_4, \quad 10_F^i = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & u_b^c & -u_g^c & u_r & d_r \\ -u_g^c & 0 & u_r^c & u_g & d_g \\ u_g^c & -u_r^c & 0 & u_b & d_b \\ -u_r & -u_g & -u_b & 0 & e^c \\ -d_r & -d_g & -d_b & -e^c & 0 \end{pmatrix}_i, \quad (2.12)$$

where $i = 1 - 3$ and $a = 1 - 4$ are generation indices. Note that d_4 is an $SU(2)_L$ singlet while $d_{1,2,3}$ belong to doublets. The complete Yukawa interactions in our model take the following form:

$$-\mathcal{L}_Y = \frac{1}{4} 10_F^i Y_{10}^{ij} 10_F^j 5_H + \sqrt{2} \bar{5}_F^a Y_5^{aj} 10_F^j 5_H^* + \bar{5}_F^a \underbrace{(\mu_a + \eta_a 24_H)}_{\equiv \xi_a} 5_F^4 + Y_A^{ab} \bar{5}_F^a \bar{5}_F^b 10_H + Y_S^{ij} 10_F^i 10_F^j 50_H. \quad (2.13)$$

Here, Y_{10} is a 3×3 symmetric matrix, Y_5 is 4×3 arbitrary, ξ_a is 4×1 arbitrary, Y_S is 3×3 symmetric, and Y_A is 4×4 antisymmetric matrices in flavor space. By overall rotations in flavor space that commute with $SU(5)$ one can bring Y_5 to a diagonal form given by

$$Y_5^{\text{diag}} = \begin{pmatrix} y_1 & 0 & 0 \\ 0 & y_2 & 0 \\ 0 & 0 & y_3 \\ 0 & 0 & 0 \end{pmatrix}, \quad (2.14)$$

while maintaining the symmetry properties of Y_S and Y_A . We also define $\hat{Y}_5^{\text{diag}} = \text{diag}(y_1, y_2, y_3)$.

3 Fermion Masses

3.1 Charged fermion mass

Once the electroweak symmetry is broken, the first three terms in Eq. (2.13) determine the charged fermion masses, which read

$$-\mathcal{L}_Y = L^T M_E E^c + D^T M_D D^c + u^T M_U u^c, \quad (3.1)$$

$$M_U = v_5 Y_{10}, \quad M_D = \begin{pmatrix} v_5 \hat{Y}_5^{\text{diag}} & 0 \\ \xi_D^T & \xi_{D_4} \end{pmatrix}, \quad M_E = \begin{pmatrix} v_5 \hat{Y}_5^{\text{diag}} & \xi_E \\ 0 & \xi_{E_4} \end{pmatrix}. \quad (3.2)$$

In the above matrices, we have defined

$$\xi_{D_a} = \mu_a + 2\eta_a v_{24}, \quad \xi_{E_a} = \mu_a - 3\eta_a v_{24}, \quad (3.3)$$

$$\xi_D = \left(\xi_{D_1} \ \xi_{D_2} \ \xi_{D_3} \right)^T, \quad \xi_E = \left(\xi_{E_1} \ \xi_{E_2} \ \xi_{E_3} \right)^T, \quad (3.4)$$

and the fields

$$L = (\ell_1, \ell_2, \ell_3, \ell_4)^T, \quad E^c = (e_1^c, e_2^c, e_3^c, e_4^c)^T, \quad (3.5)$$

$$D = (d_1, d_2, d_3, d_4)^T, \quad D^c = (d_1^c, d_2^c, d_3^c, d_4^c)^T. \quad (3.6)$$

A crucial point to note is the difference between ξ_D and ξ_E , arising from the GUT breaking VEV of 24_H , which helps correct the wrong mass relations of $SU(5)$.

As will be shown later in Sec. 5, from the gauge coupling unification constraints, the vector-like lepton doublet should have a mass near the GUT scale. Therefore, we integrate it out, which yields the light $3 \times$ charged lepton mass matrix and the heavy vector-like lepton mass as [44]

$$M_E^{\text{light}} = \left(\mathbb{1} + \frac{1}{\xi_{E4}^2} \xi_E \xi_E^\dagger \right)^{-1/2} v_5 Y_5, \quad (3.7)$$

$$M_E^{\text{heavy}} = \left(\xi_E^\dagger \xi_E + \xi_{E4}^2 \right)^{1/2} \sim M_{\text{GUT}}. \quad (3.8)$$

The vector-like down-type quark, on the other hand, remains at the TeV scale to maximize the GUT scale – so that proton lifetime limits are satisfied, as discussed in Sec. 5. Hence, for our numerical analysis, we diagonalize the full 4×4 matrix. However, approximate formulas can provide perfect agreement with full numerical solution:

$$M_D^{\text{light}} = v_5 Y_5^T \left(\mathbb{1} + \frac{1}{\xi_{D4}^2} \xi_D \xi_D^\dagger \right)^{-1/2}, \quad (3.9)$$

$$M_D^{\text{heavy}} = \left(\xi_D^\dagger \xi_D + \xi_{D4}^2 \right)^{1/2} \sim \text{TeV}. \quad (3.10)$$

The reason for this excellent agreement is that the VLQs must have masses at least of order TeV, while the light down-type quarks have masses at most above 3 GeV. Analytic solutions to Eqs. (3.7) and (3.9) showing the consistency of down-type quark and charged lepton masses are also discussed in Ref. [24].

It is conceivable that in presence of the scalar fields 10_H and 50_H , the wrong mass relations of $SU(5)$ among the charged fermions can be corrected via loop diagrams, without the need for the vector-like fermions in the $5_F + \bar{5}_F$ representation. While mass relations involving the first two generation quark and leptons can indeed be corrected via loop diagrams involving the exchange of η_3 and χ_3 fields (Cf: Eq. (2.3)-(2.4)), owing to the antisymmetry of Y_5 , the third family fermions receive too small a correction to correct for the wrong mass ratio $m_b^0/m_\tau^0 = 1$. We conclude that the vector-like fermions are essential in this setup for correcting all mass relations.

3.2 A fit to the charged fermion masses

Here, we carry out a numerical study showing the consistency of charged fermion masses. In particular, we simultaneously fit the down-type quark and the charged fermion masses obtained from the mass matrices of Eq. (3.2). For this fit, we take the input values of the masses and mixing parameters at the GUT scale from Ref. [45], which we summarize in Table 1.

As will be shown later, gauge coupling unification requires the vector-like down-type quark (denoted as B) to have a mass of order the TeV scale. The current LHC bound on the mass of these states is around $m_B \gtrsim 1.5$ TeV [46, 47]. Therefore, for our benchmark fit, we take its mass to be $m_B \simeq 3$ TeV, such that collider constraints are safely satisfied. The presence of TeV scale

Masses (in GeV)	Inputs (at $\mu = M_{GUT}$)	Fitted values (at $\mu = M_{GUT}$)
$m_d/10^{-3}$	1.14 ± 0.11	1.14
$m_s/10^{-3}$	21.58 ± 1.14	21.58
m_b	0.994 ± 0.009	0.994
$m_e/10^{-3}$	0.470692 ± 0.000470	0.469544
$m_\mu/10^{-3}$	99.3658 ± 0.0993	99.2097
m_τ	1.68923 ± 0.00168	1.68976
θ_{12}^{CKM}	0.22739 ± 0.0006	0.2276
$\theta_{23}^{\text{CKM}}/10^{-2}$	4.858 ± 0.06	0.0486
$\theta_{13}^{\text{CKM}}/10^{-3}$	4.202 ± 0.13	0.00421
δ^{CKM}	1.207 ± 0.054	1.203

Table 1. Inputs [45] and outputs for the numerical χ^2 analysis. This benchmark fit with a total $\chi^2 = 0.15$ shows excellent agreement with data. As an example, for this fit, we additionally demand that the heavy down-type vectorlike fermion mass is $m_B \sim 3$ TeV, which safely evades all present collider bounds.

vector-like quarks, in general, can mediate flavor violating processes owing to mixing with the light quarks. For the benchmark fit presented below, we find that all flavor violating processes are well under control. In our numerical code, we have checked that the relevant constraints are satisfied, following those derived in Ref. [48–52].

A benchmark scenario that reproduces the down-type quarks and charged leptons masses, and satisfies all experimental constraints is given below:

$$(y_1, y_2, y_3) = (1.05 \times 10^{-4}, 6.53 \times 10^{-4}, 9.77 \times 10^{-3}), \quad (3.11)$$

$$(\xi_{E_1}, \xi_{E_2}, \xi_{E_3})/\xi_{E_4} = (38.506, 22.009, 5.283), \quad (3.12)$$

$$(\xi_{D_1}, \xi_{D_2}, \xi_{D_3}, \xi_{D_4}) = (183.15e^{i0.049}, 1747.08e^{-i3.099}, 2459.96e^{i0.155}, 20.96) \text{ GeV}. \quad (3.13)$$

Since the vector-like lepton has a mass close to the GUT scale, for the purpose of fitting charged fermion masses, only the ratios ξ_{E_i}/ξ_{E_4} are relevant. However, since the vector-like down-type quark has a mass close to the TeV scale, values of all ξ_{D_a} are needed to determine its mass as well as for the computation of flavor violating processes. The input values of the masses and the fitted values are listed in Table 1. It is to be noted that the input values at the GUT scale given in Table 1 assume SM particle spectrum in between M_Z scale and the M_{GUT} scale. In our model, there are additional states that have masses below the GUT scale, which would impact the running of the fermion mass parameters. However, we expect that the modifications needed to correct for this running will not be significant. Moreover, any relevant deviations from the values given in Table 1 can be incorporated given the freedom we have in this theory.

3.3 Flavor violation

For completeness, in the following, we also present the couplings that are responsible for mediating flavor violating process in the quark sector. First, we make a change of basis,

$$D^T M_D D^c \rightarrow \bar{D}_L \hat{M}_D D_R, \quad \hat{M}_D = M_D^*, \quad (3.14)$$

and diagonalize this 4×4 matrix as

$$\hat{M}_D^{\text{diag}} = V_L^{d\dagger} \hat{M}_D V_R^d. \quad (3.15)$$

We further define

$$V_L^d = \begin{pmatrix} X_L \\ Y_L \end{pmatrix}, V_R^d = \begin{pmatrix} X_R \\ Y_R \end{pmatrix}, \quad (3.16)$$

such that the $X_{L,R}$ are the upper 3×4 blocks from the corresponding 4×4 matrices $V_{L,R}^d$. A similar analysis provides the matrices $V_{L,R}^u$ and $V_{L,R}^\ell$ in the up-quark and the charged lepton sectors. Furthermore, we define the mass eigenstates as

$$D_{L,R} = \left(d \ s \ b \ B \right)_{L,R}^T, \quad (3.17)$$

where B represents the bottom-like vector-like quark. As we shall see shortly, this would correspond to a third generation vector-like quark.

With these definitions, the charged current interactions can be written as [52],

$$-\mathcal{L}_W^{\text{CC}} \supset \frac{g}{\sqrt{2}} \bar{u}_L V \gamma^\mu D_L W_\mu^+ + h.c., \quad (3.18)$$

where $V = V_L^{u\dagger} X_L$ is a 3×4 matrix. Since there is no up-type VLQ, V_L^u is a 3×3 unitary matrix that diagonalizes the up-quark mass matrix. Therefore, the Cabibbo–Kobayashi–Maskawa (CKM) matrix can be identified with the upper 3×3 block of V , i.e., $V_{\text{CKM}} = V_{3 \times 3}^{\text{upper}}$. During the fitting procedure, we also demand that the CKM matrix is correctly reproduced in a way that all non-unitarity constraints satisfied. For this purpose, we parametrize V_L^u as $V_L^u = V_{\text{CKM-like}}^u(\theta_{ij}^u, \delta^u) \text{diag}(e^{i\alpha^u}, e^{i\beta^u}, 1)$. The input parameters in the CKM as well as the fitted values are also summarized in Table 1.

The neutral current interactions, on the other hand, take the form [52],

$$-\mathcal{L}_Z^{\text{NC}} \supset \frac{g}{2 \cos \theta_W} \bar{D}_L F^d \gamma^\mu D_L Z_\mu, \quad (3.19)$$

where we have defined $F^d = X_L^\dagger X_L$. Deviation of F^d from the unit matrix gives rise to flavor changing neutral current (FCNC) processes, such as meson decay and meson-antimeson oscillations. The coupling responsible for Higgs-mediated FCNC take the form [50]

$$-\mathcal{L}_h \supset \bar{D}_L Y_h D_R \frac{h}{\sqrt{2}} + h.c., \quad (3.20)$$

here we have defined $Y_h = X_L^\dagger \hat{Y}_5^{\text{diag}} X_R$.

Along with the fit parameters given in Eqs. (3.11)-(3.13), the CKM parameters are correctly reproduced via

$$(\theta_{12}^u, \theta_{23}^u, \theta_{13}^u, \delta^u, \alpha^u, \beta^u) = (0.765, 0.0613, 0.0347, 0.166, 1.034, -1.175). \quad (3.21)$$

Eqs. (3.11)-(3.13), together with Eq. (3.21), let us compute the relevant matrices as:

$$X_L = \begin{pmatrix} 0.54e^{-i1.52} & 0.83e^{-i3.09} & 0.0015e^{i0.05} & 3.65 \times 10^{-7}e^{i1.62} \\ 0.83e^{i1.61} & 0.54e^{-i3.09} & 0.092e^{-i3.09} & 2.1 \times 10^{-5}e^{-i1.52} \\ 0.078e^{-i1.41} & 0.049e^{i0.15} & 0.99e^{-i2.98} & 4.5 \times 10^{-4}e^{i1.72} \end{pmatrix}, \quad (3.22)$$

$$F^d = \begin{pmatrix} 1. & -1.85 \times 10^{-9} & 2.46 \times 10^{-8} & -5 \times 10^{-5} \\ 1.85 \times 10^{-9} & 1. & 1.55 \times 10^{-8} & 3 \times 10^{-5} \\ -2.46 \times 10^{-8} & 1.55 \times 10^{-8} & 1. & -4 \times 10^{-4} \\ -5 \times 10^{-5} & -3 \times 10^{-5} & 4 \times 10^{-4} & 2.10 \times 10^{-7} \end{pmatrix}, \quad (3.23)$$

$$V = \begin{pmatrix} 0.97e^{-i2.55} & 0.225e^{i2.16} & 0.0485e^{-i1.11} & 2.3 \times 10^{-5}e^{i0.69} \\ 0.225e^{i2.77} & 0.974e^{-i1.91} & 0.0042e^{i2.27} & 4.6 \times 10^{-5}e^{-i0.31} \\ 0.047e^{-i1.26} & 0.013e^{-i3.14} & 0.99e^{-i2.98} & 4.5 \times 10^{-4}e^{i1.72} \end{pmatrix}, \quad (3.24)$$

$$Y_h = \begin{pmatrix} 6.53 \times 10^{-6} & 0 & 0 & -9.4 \times 10^{-4} \\ 0 & 1.2 \times 10^{-4} & 0 & 5.9 \times 10^{-4}i \\ 0 & 0 & 5.7 \times 10^{-3} & -7.8 \times 10^{-3}i \\ -3.54 \times 10^{-10} & 0 & -4.25 \times 10^{-9}i & 2.59 \times 10^{-6}i & 3.65 \times 10^{-6} \end{pmatrix}. \quad (3.25)$$

As can be seen from these matrices, all flavor violating processes are highly suppressed. Furthermore, Eq. (3.24) depicts that the unitarity of the 3×3 CKM matrix is preserved to a high degree. As an example, we compute the decay $\mathcal{B}_{d,s} \rightarrow \mu\bar{\mu}$. The SM predictions for such processes are $BR(\mathcal{B}_d \rightarrow \mu^+\mu^-) = (1.12 \pm 0.12) \times 10^{-10}$ and $BR(\mathcal{B}_s \rightarrow \mu^+\mu^-) = (3.52 \pm 0.15) \times 10^{-9}$ [53]. The new physics contribution is parameterized by [49]

$$\Delta_{\mu\mu}^{\mathcal{B}_q} = -\frac{\pi s_W^2}{\alpha_{\text{em}}} F_{qb}^d, \quad (3.26)$$

such that the modified branching ratio is given by

$$BR(\mathcal{B}_q \rightarrow \mu^+\mu^-) = \tau_{\mathcal{B}_q} \frac{G_F^2}{16\pi} \left(\frac{\alpha_{\text{em}}}{\pi s_W^2} \right)^2 f_{\mathcal{B}_q}^2 m_{\mathcal{B}_q} m_\mu^2 \sqrt{1 - \frac{4m_\mu^2}{m_{\mathcal{B}_q}^2}} |\eta_Y^2| |\lambda_{qb}^t Y_0(x_t) + \Delta_{\mu\mu}^{\mathcal{B}_q}|^2. \quad (3.27)$$

By demanding that the new contribution be smaller than the SM prediction at 95% C.L, the corresponding constraints yields

$$|F_{db}^d| < 1 \times 10^{-4}, \quad |F_{sb}^d| < 4.2 \times 10^{-4}. \quad (3.28)$$

As can be seen from Eq. (3.23), the corresponding F_{ij}^d are about four orders of magnitude smaller. Since the FCNC couplings scale inversely as m_B^2 , if $m_B \sim 30$ GeV is assumed these modifications would become significant. However, such low values of m_B are excluded by direct search limits on vector-like quarks.

Finally, using the flavor violating couplings quoted above, one can straightforwardly compute the decay rates of the vectorlike quark [50], and we find

$$\Gamma(B \rightarrow W^-t) : \Gamma(B \rightarrow Zb) : \Gamma(B \rightarrow hb) = 2 : 1 : 1, \quad (3.29)$$

as expected from ‘Higgs boson equivalence theorem’. These are the dominant decay modes of B showing that it can be identified as the third generation vector-like quark (due to $B \rightarrow W^-t$, $B \rightarrow Zb$, $B \rightarrow hb$ dominant decay modes). The corresponding Higgs couplings are given by [50]

$$-\mathcal{L}_h \supset \frac{gm_B}{2m_W} (\bar{d} \bar{s} \bar{b}) \{Y_h^L P_L + Y_h^R P_R\} B h + h.c., \quad (3.30)$$

$$Y_h^L = \begin{pmatrix} -5.42 \times 10^{-5} & 3.41 \times 10^{-5}i & -4.54 \times 10^{-4}i \end{pmatrix}^T, \quad (3.31)$$

$$Y_h^R = \begin{pmatrix} -2.04 \times 10^{-11} & -2.44 \times 10^{-10}i & 1.49 \times 10^{-7}i \end{pmatrix}^T. \quad (3.32)$$

Although they turn out to be subdominant, the model allows us to calculate other branching ratios, such as $W + \text{jets}$, $h + \text{jets}$ and $Z + \text{jets}$ where jets refer to light quarks. For example,

Figure 1. Two-loop Feynman diagrams generating Majorana neutrino masses in the Zee-Babu model. Left panel shows the standard Zee-Babu diagram with color-neutral scalars (singly and doubly charged states), while the right panel shows the additional diagram with colored scalars (color-triplet and color-sextet states). Gauge coupling unification constraints within our unified framework guarantees that both these diagrams must contribute equally to the neutrino mass generation.

from the fits we find that $Br(B \rightarrow W + \text{jets}) = 0.65\%$, $Br(B \rightarrow Z + \text{jets}) = 0.5\%$, and $Br(B \rightarrow h + \text{jets}) = 0.5\%$. We find it interesting that, in principle, GUT scale relations can be tested in decay properties of a surviving light state.

We have explicitly checked numerically that consistent fermion mass fit can be obtained including satisfying all flavor violating processes as long as $m_B \gtrsim 35$ GeV. Below this mass, we find that it violates the $\mathcal{B}_{d,s} \rightarrow \mu^+ \mu^-$ decay constraints. Therefore, from the analysis of this section, we see that collider constraints provide the best limit on the mass of the vector-like quark.

3.4 Neutrino mass generation

Neutrino masses are generated via two-loop diagrams in the model as shown in Fig. 1. As can be seen from these figures, there is a Feynman diagram with charged scalars that carry no color (η_1^+ and χ_1^{--} of the standard Zee-Babu diagram in the left panel), as well as a second diagram with colored particles (η_3 and χ_5 , right panel) propagating inside the loop. As we will show, an interesting consequence of the unified framework is that demanding neutrino mass generation via the Zee-Babu diagram with color-neutral (colored) particles automatically requires that the colored (color-neutral) states must also be light, and therefore, both diagrams contribute equally to the neutrino masses.

Since in the neutrino mass diagram, charged leptons and down-type quarks propagate inside loops, we need to compute the neutrino mass formula in the mass diagonal basis of the charged fermions. Therefore, we diagonalize these matrices, given in Eq. (3.2), in the following way:

$$(M_E)_{4 \times 4} = U_L^e M_E^{\text{diag}} U_R^{e\dagger}, \quad (M_D)_{4 \times 4} = U_L^d M_D^{\text{diag}} U_R^{d\dagger}, \quad (3.33)$$

such that

$$L = U_L^{e*} L_0, \quad E^c = U_R^e E_0^c, \quad D = U_L^{d*} D_0, \quad D^c = U_R^d D_0^c, \quad (3.34)$$

where, f_0 represents mass eigenstates. With these rotations, the relevant interactions for neutrino mass generations can be obtained as follows:

$$\bar{5}_F Y_A \bar{5}_F 10_H \supset L^T C Y_A L \eta_1 + L^T C Y_A d^c \eta_3 \quad (3.35)$$

$$\supset \nu^T C \underbrace{\left(U_L^{e\dagger} Y_A U_L^{e*} \right)}_{\equiv \hat{Y}_A|_{4 \times 4}} e_0 \eta_1^+ + \nu^T C \underbrace{\left(U_L^{e\dagger} Y_A U_R^d \right)}_{\equiv \tilde{Y}_A|_{4 \times 4}} d_0^c \eta_3^{-1/3}, \quad (3.36)$$

Although \hat{Y}_A remains anti-symmetric, \tilde{Y}_A is no longer anti-symmetric. For the latter, it is not required by the SM gauge symmetry. Furthermore,

$$10_F Y_S 10_F 50_H \supset e^{cT} C Y_S e^c \chi_1 + Q^T C Y_S Q \chi_5 \quad (3.37)$$

$$\supset e_0^{cT} C \underbrace{\left(\tilde{U}_R^{eT} Y_S \tilde{U}_R^e \right)}_{\equiv \hat{Y}_S|_{4 \times 4}} e_0^c \chi_1 + d_0^T C \underbrace{\left(\tilde{U}_L^{d\dagger} Y_S \tilde{U}_L^{d*} \right)}_{\equiv \tilde{Y}_S|_{4 \times 4}} d_0 \chi_5. \quad (3.38)$$

Note that both \hat{Y}_S and \tilde{Y}_S remain symmetric, which is required by SM gauge symmetry. Here we have defined \tilde{U}_R^e to be the upper 3×4 matrix of the 4×4 U_R^e matrix (and same for U_L^d). Since Y_S is a 3×3 matrix we needed a change of basis that takes $f^i \rightarrow f_a^0$, with f_a^0 being the mass eigenstates. All four mass eigenstates run inside the loop of the neutrino diagram (including singly-charged vector-like lepton which has a mass of order the GUT scale). Thus, \hat{Y}_S and \tilde{Y}_S become 4×4 despite the fact that the original Y_S is a 3×3 matrix. (However, we find that when E runs inside the loop, the diagram is suppressed, see below.)

The 4×4 Majorana neutrino mass matrix from the Zee-Babu diagrams is then given by

$$\begin{aligned} \mathcal{M}_{\text{loop}}^\nu &= \mathcal{M}_{ab}^{\nu, 4 \times 4} = 16\mu \hat{Y}_A^{ac} \left(M_E^{\text{diag}} \right)^c \hat{Y}_S^{cd} \left(M_E^{\text{diag}} \right)^d \hat{Y}_A^{db} \hat{I}_{cd} \\ &\quad + 48\mu \tilde{Y}_A^{ac} \left(M_D^{\text{diag}} \right)^c \tilde{Y}_S^{cd} \left(M_D^{\text{diag}} \right)^d \tilde{Y}_A^{db} \tilde{I}_{cd}. \end{aligned} \quad (3.39)$$

In the above, I_{cd} is the loop function (standing for \hat{I}_{cd} or a \tilde{I}_{cd}), given as [54, 55]:

$$I_{cd} = \int \frac{d^4 k}{(2\pi)^4} \int \frac{d^4 q}{(2\pi)^4} \frac{1}{(k^2 - m_c^2)} \frac{1}{(k^2 - m_{\eta_1}^2)} \frac{1}{(q^2 - m_d^2)} \frac{1}{(q^2 - m_{\eta_1}^2)} \frac{1}{((k-q)^2 - m_{\chi_1}^2)}. \quad (3.40)$$

In \hat{I}_{cd} (\tilde{I}_{cd}), m_i represents the masses of the charged leptons (down-type quarks). Moreover, the cubic coupling relevant for neutrino mass generation arises from the following term in the scalar potential:

$$V \supset \mu 10_H 10_H 50_H + h.c. \supset \mu \eta_1^- \eta_1^- \chi_1^{--} + \mu \eta_3 \eta_3 \chi_5 + h.c. \quad (3.41)$$

Finally, the full 5×5 mass matrix in the neutral fermion sector is given by

$$-\mathcal{L}_Y \supset \left(\bar{\nu}_L \quad \bar{\nu}_R^c \right) M_N \begin{pmatrix} \nu_L^c \\ \nu_R \end{pmatrix} = \left(\bar{\nu}_L \quad \bar{\nu}_R^c \right) \left(\frac{\mathcal{M}_{\text{loop}}^\nu | \Xi}{\Xi^T | 0} \right)_{5 \times 5} \begin{pmatrix} \nu_L^c \\ \nu_R \end{pmatrix}, \quad (3.42)$$

with

$$\Xi^T = \left(\xi_{E_1} \quad \xi_{E_2} \quad \xi_{E_3} \quad \xi_{E_4} \right). \quad (3.43)$$

In the above, we have defined $\nu_L = (\nu_1, \nu_2, \nu_3, \nu_4) \subset \bar{5}_F^a$. Note that ν^c and $\bar{\nu}^c = \nu_4$ vector-like neutral leptons are part of $SU(2)_L$ doublets.

We block diagonalize the M_N matrix in the following way:

$$M_N = \left(\frac{\mathcal{M}_{\text{loop}}^{\nu, 4 \times 4} | \Xi}{\Xi^T | 0} \right)_{5 \times 5} = N_L M_N^{BD} N_L^T, \quad (3.44)$$

Figure 2. Feynman diagram representing Majorana neutrino mass generation at the one-loop order. Within our model, this contribution to the neutrino masses is tiny, see text for details.

such that

$$M_N^{BD} = \left(\begin{array}{c|c} A_{3 \times 3} & 0 \\ \hline 0 & D_{2 \times 2} \end{array} \right)_{5 \times 5}, \quad (3.45)$$

where we have defined

$$A = \mathcal{M}_{\text{loop}}^{\nu, 3 \times 3}, \quad B = \begin{pmatrix} \left(\mathcal{M}_{\text{loop}}^{\nu} \right)_{14} & \xi_{E_1} \\ \left(\mathcal{M}_{\text{loop}}^{\nu} \right)_{24} & \xi_{E_2} \\ \left(\mathcal{M}_{\text{loop}}^{\nu} \right)_{34} & \xi_{E_3} \end{pmatrix}, \quad C = \begin{pmatrix} \left(\mathcal{M}_{\text{loop}}^{\nu} \right)_{44} & \xi_{E_4} \\ \xi_{E_4} & 0 \end{pmatrix}, \quad (3.46)$$

$$D = C - B^T A^{-1} B, \quad \text{and,} \quad N_L = \begin{pmatrix} 1 & 0 \\ B^T A^{-1} & 1 \end{pmatrix}. \quad (3.47)$$

Hence, the light neutrino mass matrix, $A = \mathcal{M}_{\text{loop}}^{\nu, 3 \times 3}$, is directly calculated using the formula of Eq. (3.39). In the original Zee-Babu model, the lightest neutrino is massless at two-loop level. In our present model, this is no longer the case since $\det(\mathcal{M}_{\text{loop}}^{\nu, 3 \times 3}) \neq 0$. However, this result holds true, although approximately.

The neutrino mass contribution from E lepton is highly suppressed, since it scales as $m_\nu \sim (\hat{Y}_A^2 \hat{Y}_S / (16\pi^2)^2) (\mu v^2 / M_E)$, and since the mass of E is near the GUT scale. Note that the parameter μ , which also appears in the cubic coupling $\mu \eta_1^+ \eta_1^+ \chi_1^-$ cannot be much larger than the masses of η_1^+ and k^{--} owing to perturbative unitarity requirements, has a value in the multi-TeV range. This makes the loop contribution arising from E -lepton exchange to be suppressed. The color-neutral scalar exchange diagram alone would then imply $m_1 \simeq 0$ for the lightest neutrino mass, owing to the determinant of \hat{Y}_A being zero for the upper 3×3 block. However, the contributions from the B quark to the neutrino mass are not suppressed, which would imply that m_1 is non-zero at the two-loop level. However, since the B -quark contributions are somewhat suppressed owing to the large B -quark mass and small mixing with the lighter quarks, we find that $m_1 \ll m_{2,3}$ in the model.

It is worth mentioning that within this model, apart from the two-loop Zee-Babu diagram, there is a further contribution to the neutrino masses [34, 56] arising from a one-loop diagram where charged scalars Φ_2^\pm and η_1^\pm run inside the loop along with the vector-like singly charged leptons ℓ_4^\pm , as shown in Fig. 2. As discussed in Sec. 5 unification section, within our scenario, both these states Φ_2 and L_4 need to be superheavy (typically close to the GUT scale) to

evade experimental bounds on proton decay. Therefore, their contributions to the neutrino mass matrix are found to be small. The contribution to the neutrino mass from this one-loop diagram can be estimated as follows [56]:

$$M_\nu \sim \frac{y_1 y_2 \lambda}{16\pi^2} \frac{v_5^2 m_{L_4}}{m_{\max}^2}, \quad m_{\max} = \max(m_{L_4}, m_{\Phi_2}) \quad (3.48)$$

$$\sim (y_1 y_2 \lambda) (10^{-13} - 10^{-14}) \text{ GeV}, \quad (3.49)$$

depending on the value of m_{\max} in the range $(10^{15} - 10^{16})$ GeV. Here, $y_{1,2}$ represent the relevant Yukawa couplings and λ is the coefficient of the quartic coupling $5_H^2 24_H 10_H^*$ needed to complete the one-loop neutrino mass diagram.

4 Perturbativity bounds on the Yukawa couplings

Before moving to the gauge coupling unification analysis, in this section, we study perturbativity bounds on the Yukawa couplings and find the upper bounds on the Yukawa couplings involving the Zee-Babu scalars. In particular, we find the maximum values of Yukawa couplings at the low scale demanding that they remain perturbative up to the GUT scale. For this analysis, here we assume that the color-neutral as well as the colored Zee-Babu states all have masses at the TeV scale. Then, the evolution of the gauge and the Yukawa couplings are governed by the one-loop renormalization group equations (RGEs) given by

$$16\pi^2 \beta_{g_i} = 16\pi^2 \mu \frac{dg_i}{d\mu} = a_i g_i^3, \quad (a_1, a_2, a_3) = \left(\frac{83}{15}, \frac{4}{3}, -\frac{25}{6}\right). \quad (4.1)$$

And the RGEs corresponding to the Yukawa couplings defined as¹

$$\mathcal{L} \supset H^* d^c Y_d Q + H^* e^c Y_e L + u^c Y_u Q H + L Y_h L \eta_1^\dagger + e^c Y_k e^c \chi_1^{--} + L Y_\eta d^c \eta_3 + Q Y_\chi Q \chi_5, \quad (4.2)$$

take the following form:

$$16\pi^2 \beta_{Y_u} = Y_u \left\{ \frac{3}{2} Y_u^\dagger Y_u - \frac{3}{2} Y_d^\dagger Y_d - \frac{17}{20} g_1^2 - \frac{9}{4} g_2^2 - 8g_3^2 + \text{Tr} \left[Y_e^\dagger Y_e + 3Y_d^\dagger Y_d + 3Y_u^\dagger Y_u \right] \right\} + \left\{ 6Y_u Y_\chi^* Y_\chi \right\}, \quad (4.3)$$

$$16\pi^2 \beta_{Y_d} = Y_d \left\{ \frac{3}{2} Y_d^\dagger Y_d - \frac{3}{2} Y_u^\dagger Y_u - \frac{1}{4} g_1^2 - \frac{9}{4} g_2^2 - 8g_3^2 + \text{Tr} \left[Y_e^\dagger Y_e + 3Y_d^\dagger Y_d + 3Y_u^\dagger Y_u \right] \right\} + \left\{ 6Y_d Y_\chi^* Y_\chi + Y_\eta^T Y_\eta^* Y_d \right\}, \quad (4.4)$$

$$16\pi^2 \beta_{Y_e} = Y_e \left\{ \frac{3}{2} Y_e^\dagger Y_e - \frac{9}{4} g_1^2 - \frac{9}{4} g_2^2 + \text{Tr} \left[Y_e^\dagger Y_e + 3Y_d^\dagger Y_d + 3Y_u^\dagger Y_u \right] \right\} + \left\{ 2Y_e Y_h^\dagger Y_h + 2Y_k Y_k^* Y_e + \frac{3}{2} Y_e Y_\eta^* Y_\eta^T \right\}, \quad (4.5)$$

$$16\pi^2 \beta_{Y_k} = \left\{ -\frac{18}{5} g_1^2 + 2\text{Tr} \left[Y_k Y_k^\dagger \right] \right\} Y_k + Y_e Y_e^\dagger Y_k + Y_k Y_e^* Y_e^T + 4Y_k Y_k^\dagger Y_k, \quad (4.6)$$

$$16\pi^2 \beta_{Y_h} = \left\{ -\frac{9}{10} g_1^2 - \frac{9}{2} g_2^2 + 4\text{Tr} \left[Y_h Y_h^\dagger \right] \right\} Y_h + \frac{1}{2} Y_h Y_e^\dagger Y_e + \frac{1}{2} Y_e^T Y_e^* Y_h + 4Y_h Y_h^\dagger Y_h$$

¹Recall that at the GUT scale, Yukawa couplings in the flavor (mass) basis satisfy $Y_h = Y_\eta = Y_A$ ($Y_h = \hat{Y}_A$, $Y_\eta = \tilde{Y}_A$) and $Y_k = Y_\chi = Y_S$ ($Y_k = \hat{Y}_S$, $Y_\chi = \tilde{Y}_S$).

$$+ \frac{3}{2}Y_h Y_\eta^* Y_\eta^T + \frac{3}{2}Y_\eta Y_\eta^\dagger Y_h, \quad (4.7)$$

$$16\pi^2\beta_{Y_\eta} = Y_\eta \left\{ -\frac{13}{20}g_1^2 - \frac{9}{4}g_2^2 - 4g_3^2 + \text{Tr} [Y_\eta Y_\eta^\dagger] \right\} \\ + \left\{ 2Y_h Y_h^\dagger Y_\eta + Y_\eta Y_d^* Y_d^T + \frac{1}{2}Y_e^T Y_e^* Y_\eta + \frac{5}{2}Y_\eta Y_\eta^\dagger Y_\eta \right\}, \quad (4.8)$$

$$16\pi^2\beta_{Y_\chi} = Y_\chi \left\{ -\frac{1}{10}g_1^2 - \frac{9}{2}g_2^2 - 8g_3^2 + 2\text{Tr} [Y_\chi Y_\chi^\dagger] \right\} \\ + \left\{ \frac{1}{2}Y_\chi Y_d^\dagger Y_d + \frac{1}{2}Y_\chi Y_u^\dagger Y_u + \frac{1}{2}Y_d^T Y_d^* Y_\chi + \frac{1}{2}Y_u^T Y_u^* Y_\chi + 12Y_\chi Y_\chi^* Y_\chi \right\}. \quad (4.9)$$

We have used the program SARAH [57] to obtain these RGEs.

Taking these RGEs listed above and turning on each entry of Y_h at a time, we compute the maximum value of the corresponding Yukawa coupling at the low scale. For this evolution, we run these parameters from TeV to the GUT scale, which we fix at 2×10^{16} GeV. For the analysis the gauge couplings and charged fermion masses are taken as inputs at the 1 TeV scale from Ref. [58]. We repeat the same procedure for Y_k, Y_η , and Y_χ . The results we obtain are summarized below:

$$Y_h^{ij} \leq 0.56; \quad (\text{antisymmetric}), \quad (4.10)$$

$$Y_\eta^{ij} \leq 1.2, \quad \text{except, } Y_\eta^{i=j=3} \leq 2.2, \quad (4.11)$$

$$Y_k^{i=j}, Y_k^{i \neq j} \leq 0.71, 0.62; \quad (\text{symmetric}), \quad (4.12)$$

$$Y_\chi^{ij} \leq \begin{pmatrix} 0.79 & 0.74 & 0.73 \\ & 0.79 & 0.73 \\ & & 0.76 \end{pmatrix}; \quad (\text{symmetric}). \quad (4.13)$$

Using these perturbativity bounds on the Yukawa couplings, one can estimate the upper bounds on the Zee-Babu states. We obtain this approximate bound knowing that in the Zee-Babu model, neutrino mass, for the case of normal mass ordering, is dominated by the (2,2)-entry [54] of the doubly charged Yukawa coupling, namely, $Y_k^{(22)}$, and therefore

$$m_\nu \sim \frac{1}{16\pi^2} \left(16Y_h^2 Y_k^{(22)} m_\mu^2 + 48Y_\eta^2 Y_\chi^{(22)} m_s^2 \right) / m_{\max} \sim 0.05 \text{ eV} \Rightarrow m_{\max} = 410 \text{ TeV}. \quad (4.14)$$

Here we have assumed $\hat{I}, \tilde{I} \sim (16\pi^2)^{-1} m_{\max}^{-2}$ and $\mu \sim m_{\max}$.

On the contrary, for the inverted mass ordering, the dominated Yukawa coupling is (2,3)-entry ($Y_k^{(23)}$) [59]. Therefore, replacing $Y_{k,\chi}^{(22)} \rightarrow Y_{k,\chi}^{(23)}$ in the above formula, we obtain $m_{\max} = 377$ TeV. Accordingly, perturbativity condition on the Yukawa couplings demand the Zee-Babu states to reside $m_{\max} \lesssim \mathcal{O}(100)$ TeV. Perturbative unitarity suggests [54, 59] that μ cannot be more than about 3 to 5 times the largest mass running in the loop [60]. Allowing $\mu \sim 3m_{\max}$ gives $m_{\max} = 1230$ TeV (normal mass ordering), $m_{\max} = 1130$ TeV (inverted mass ordering).

Figure 3. An illustration of two-loop gauge coupling unification for a benchmark scenario given in Table 2.

5 Gauge coupling unification and proton decay bounds

In this section, we perform a dedicated study to the gauge coupling unification. The two-loop RGEs [61–63] for the gauge couplings can be written as

$$\mu \frac{dg_i}{d\mu} = \frac{\beta_{1\text{-loop}}^{g_i}}{16\pi^2} + \frac{\beta_{2\text{-loop}}^{g_i}}{(16\pi^2)^2}, \quad (5.1)$$

where $\beta_{1\text{-loop}}^{g_i}$ is the one-loop and $\beta_{2\text{-loop}}^{g_i}$ is the two-loop contribution given by

$$\beta_{1\text{-loop}}^{g_i} = \left\{ a_i^{\text{SM}} + \sum_X \mathcal{H}(\mu, m_X) \Delta a_i^X \right\} g_i^3, \quad (5.2)$$

$$\beta_{2\text{-loop}}^{g_i} = \sum_k b_{ik}^{\text{SM}} g_k^2 + \sum_X \sum_k \Delta b_{ik}^X g_k^2 \mathcal{H}(\mu, m_X), \quad (5.3)$$

where the contributions from the Yukawa couplings are ignored and $i, k = 1 - 3$. The sum is taken over all beyond the SM (BSM) states, X . The Heaviside-Theta function is defined in the following way:

$$\mathcal{H}(\mu, m) = \begin{cases} 1, & \text{for } \mu \geq m, \\ 0, & \text{for } \mu < m. \end{cases} \quad (5.4)$$

Moreover, a_i^{SM} and b_{ik}^{SM} are the well known SM one-loop and two-loop β -coefficients:

$$a_i^{\text{SM}} = \left(\frac{41}{10}, -\frac{19}{6}, -7 \right), \quad (5.5)$$

$$b_{ik}^{\text{SM}} = \begin{pmatrix} \frac{199}{50} & \frac{27}{10} & \frac{44}{5} \\ \frac{9}{10} & \frac{35}{6} & 12 \\ \frac{11}{10} & \frac{9}{2} & -26 \end{pmatrix}. \quad (5.6)$$

Whereas, the BSM contributions are listed in the following:

$$\Delta a_i^{\phi_2} = \left(\frac{1}{15}, 0, \frac{1}{6} \right), \quad \Delta a_i^{\Phi_2} = \left(0, \frac{1}{3}, 0 \right), \quad \Delta a_i^{\Phi_3} = \left(0, 0, \frac{1}{2} \right), \quad (5.7)$$

Figure 4. Result from extensive Markov chain Monte Carlo (MCMC) analysis. The 1σ (dark colored band) and 2σ (light colored band) highest posterior density (HPD) intervals of the masses of all multiplets from gauge coupling unification constraints. Gray horizontal dashed line represents the approximate collider bound of $m_i \geq 1$ TeV on the states. Gray horizontal dotted line depicts the maximum allowed mass of $m_i \leq 10$ TeV on the (η_1, χ_1) states. Moreover, gray horizontal dashed-dotted line at $\mu = 10^{12}$ GeV scale shows the proton decay bounds by the color-triplet states χ_2 and ϕ_2 .

$$\Delta a_i^{\eta_1} = \left(\frac{1}{5}, 0, 0\right), \quad \Delta a_i^{\eta_2} = \left(\frac{4}{15}, 0, \frac{1}{6}\right), \quad \Delta a_i^{\eta_3} = \left(\frac{1}{30}, \frac{1}{2}, \frac{1}{3}\right), \quad (5.8)$$

$$\Delta a_i^{\chi_1} = \left(\frac{4}{5}, 0, 0\right), \quad \Delta a_i^{\chi_2} = \left(\frac{1}{15}, 0, \frac{1}{6}\right), \quad \Delta a_i^{\chi_3} = \left(\frac{49}{30}, \frac{1}{2}, \frac{1}{3}\right), \quad (5.9)$$

$$\Delta a_i^{\chi_4} = \left(\frac{32}{15}, 0, \frac{5}{6}\right), \quad \Delta a_i^{\chi_5} = \left(\frac{2}{5}, 4, \frac{5}{2}\right), \quad \Delta a_i^{\chi_6} = \left(\frac{4}{5}, \frac{4}{3}, 2\right), \quad (5.10)$$

$$\Delta a_i^{L_4} = \left(\frac{2}{5}, \frac{2}{3}, 0\right), \quad \Delta a_i^{d_4} = \left(\frac{4}{15}, 0, \frac{2}{3}\right), \quad (5.11)$$

and

Table 2. Mass spectrum associated with the benchmark gauge coupling unification presented in Fig. 3. Masses of $\chi_{4,5,6}$ are determined by the mass relations given in Eq. (2.11).

full parameter space, we perform a detailed Markov chain Monte Carlo (MCMC) analysis for the gauge coupling unification by varying all masses (by imposing the mass relations of Eq. (2.11)) and the result is depicted in Fig. 4. For definiteness, in this analysis, we restrict the Zee-Babu states, namely η_1 and χ_1 in the range $m_{\eta_1, \chi_1} \in (1, 10)$ TeV. Since the color-triplet states, χ_2 and ϕ_2 , mediate proton decay, we put a lower bound on their masses of $m_i \geq 10^{12}$ GeV [39, 64]. In Fig. 4, the darker (lighter) range represents the 1σ (2σ) highest posterior density (HPD) resulting from the MCMC analysis.

Remarkably, the special feature of our model is that both the color-neutral and the colored Zee-Babu states must contribute to neutrino masses. When gauge coupling unification constraints are imposed on top of demanding neutrino mass generation through either the color-neutral or the colored Zee-Babu states, the model unambiguously predicts the existence of both colored and color-neutral states around the TeV scale; see Fig. 4. Furthermore, consistent gauge coupling unification also calls for the vector-like singlet down-type quark to have a mass of order TeV scale, which may lead to interesting phenomenology. On the other hand, the mass of the vector-like lepton doublet is pushed close to the GUT scale, and therefore, the one-loop Zee-like neutrino mass contribution, as noted before, is negligible within this part of the parameter space.

The singly (η_1) and doubly (χ_1) charged scalars, in the standard Zee-Babu model, are expected to have masses close to the TeV scale. They, therefore, give rise to various interesting experimental signatures that include flavor violating processes as well as unique collider signatures. For experimental probes of these color-neutral states, see for example Refs. [54, 55, 59, 65–70]. As can be seen from Fig. 4, their colored partners, namely, the color-triplet (η_3) and color-sextet (χ_5), may also leave enthralling experimental signatures.

Finally, consistent gauge coupling unification points (from the above mentioned MCMC

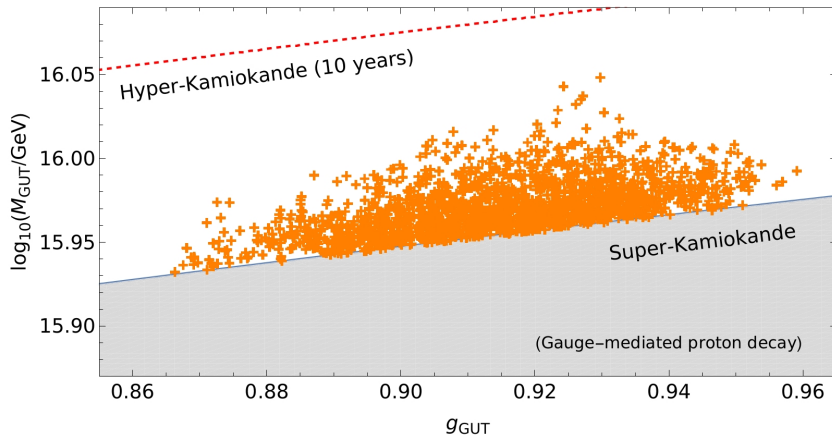

Figure 5. Result from the MCMC analysis. Consistent gauge coupling unification points and proton decay bounds in the g_{GUT} vs M_{GUT} plane. Current proton decay bound on the decay mode $p \rightarrow e^+\pi^0$ from the Super-Kamiokande is shown by the shaded gray region. Hyper-Kamiokande sensitivity after its 10 years of operation is depicted with a dashed red line.

analysis) and proton decay bounds in the g_{GUT} vs M_{GUT} plane is depicted in Fig. 5. The corresponding proton decay bound is computed as follows. The decay rate for the dominant gauge boson mediated decay $p \rightarrow e^+\pi^0$ is given as [71–73]

$$\Gamma(p^+ \rightarrow \pi^0 e^+) = \frac{\pi m_p \alpha_U^2}{4 f_\pi^2} |\alpha_H|^2 R_L^2 (1 + F + D)^2 \left(\frac{A_{SR}^2}{M_X^4} + \frac{4A_{SL}^2}{M_X^4} \right). \quad (5.17)$$

Here $f_\pi = 130.2$ MeV is the pion decay constant $D = 0.804$ and $F = 0.463$ are chiral Lagrangian parameters [74, 75], $\alpha_H = -0.01257$ GeV³ is the hadronic matrix element [76], $R_L = 1.35$ is the long-distance renormalization factor of the four-fermion operators [77], A_{SL} and A_{SR} are the short distance factors with $A_{SL} \simeq A_{SR} \simeq 2$ [78], M_X is the common mass of the (X, Y) gauge bosons, and $\alpha_{\text{GUT}} = g_{\text{GUT}}^2/(4\pi)$ is the unified coupling at the GUT scale. Note that the value of $\alpha_{\text{GUT}} \simeq 1/14$ is significantly larger than the corresponding value in typical non-supersymmetric unified theories where it is $\sim 1/40$. This increased α_{GUT} results in the shortening of proton lifetime by about an order of magnitude. For the gauge coupling unification study, we have identified the unification scale M_{GUT} with the masses of the gauge bosons, i.e., $M_{\text{GUT}} = M_{X,Y}$. Using Eq. (5.17), in Fig. 5, the current (future) proton decay bound of $\tau_p(p \rightarrow e^+\pi^0) > 2.4 \times 10^{34}$ (7.8×10^{34}) yrs from Super-Kamiokande [79] (Hyper-Kamiokande [23]) is shown with gray shaded region (red dashed line). While, a large part of the parameter space is ruled out by the present experimental limits, intriguingly, 10 yrs operation of Hyper-Kamiokande will likely probe the entire available parameter space of the proposed model.

6 Conclusions

The Zee-Babu model stands out as an economical and compelling framework for neutrino mass generation as two-loop radiative correction. In this work, we have proposed a UV-complete version of the Zee-Babu mechanism within the $SU(5)$ framework. A direct consequence of such a unified framework is that in addition to the color-neutral scalars of the Zee-Babu model, there also exist colored GUT partners of these sates. Consistency with gauge coupling unification

and neutrino oscillation data requires that both these states contribute equally to the neutrino mass generation mechanism. We show from perturbativity of the Yukawa couplings and the demand of gauge coupling unification consistent with proton decay bounds that these states should have masses below $\mathcal{O}(10^3)$ TeV, making them potentially detectable in future collider experiments. The wrong fermion mass relations of the minimal $SU(5)$ theory are corrected in this model by introducing vector-like fermions in the $5+\bar{5}$ representation of $SU(5)$. Additionally, gauge coupling unification necessitates that the vector-like down-type quark from this multiplet should have a mass near the TeV scale, which allows for its detection in collider experiments. Furthermore, our Markov chain Monte Carlo analysis of the model parameters indicates a high likelihood of detecting its signal in proton decay searches during the first decade of Hyper-Kamiokande’s operation.
