Abstract

In this work, we introduce the minimal set of leptoquarks into the 3-3-1 model with right-handed neutrinos, capable of generating radiative masses for active neutrinos. As a main consequence, the standard neutrinos acquire small Majorana masses at the one-loop level, while right-handed (sterile) neutrinos obtain small Majorana masses at the two-loop level, naturally making them light particles as well. Additionally, we discuss the viability of this scenario and several other interesting phenomenological consequences, including its impact on *B*-meson physics and rare Higgs decays, both of which are also induced by the leptoquarks.

I. INTRODUCTION

Although solar and atmospheric neutrino oscillation experiments revealed that neutrinos are massive particles two decades ago[1, 2], the problem of the smallness of the neutrino masses remains an open question in theoretical particle physics[3–6]. Such smallness is often explained through the dimension-5 Weinberg operator [7]. One common realization of this operator involves introducing a new scalar field that interacts with neutrinos and other particles, generating radiative neutrino masses via loop-level contributions [8–11]. Such mechanisms are more intricate in the context of UV-complete models, where the particle content tends to be large and diverse. When right-handed neutrinos are included, there are typically profound connections between active and sterile neutrino states. Understanding these connections is a key goal in studying UV-complete realizations of neutrino mass mechanisms [12].

Sterile neutrinos are hypothetical particles closely associated with active neutrinos. Despite their elusive nature, there are potential hints of their existence, providing significant motivation for their study. Several experimental anomalies can be better explained by the existence of sterile neutrinos that mix non-negligibly with active neutrinos, with masses in the eV scale. These anomalies include the reactor anomaly [13], the gallium anomaly [14, 15], the MiniBooNE anomaly [16], and the LSND anomaly [17]. All these short-baseline experiments exhibit tensions with the standard 3ν scenario that are naturally explained by the presence of light sterile neutrinos [18], which affect the oscillation probabilities of active neutrinos [19, 20].

In addition to eV-scale sterile neutrinos, keV-scale sterile neutrinos are highly motivated in the context of dark matter studies [21, 22]. They are a natural candidate for warm dark matter and could significantly influence the effective number of relativistic species during Big Bang Nucleosynthesis (BBN) [23, 24]. However, while light sterile neutrinos are theoretically appealing [21, 25–27], generating small sterile neutrino masses while maintaining light the active neutrinos is a nontrivial challenge.

In the context of the $SU(3)_C \times SU(3)_L \times U(1)_N$, when right-handed neutrinos appear in the fermion triplet together with active neutrinos and charged leptons, the variant is known as 331 with right-handed neutrinos (331RHN)[28, 29]. In its original version, neutrinos are massless particles. The challenge here concerning neutrino mass generation is twofold: to explain active masses and understand its consequences on sterile neutrinos. There are few attempts in the literature investigating the generation of light sterile neutrinos in the 331RHN[30–32], here, for the first

time, we address this issue by adding leptoquarks to the 331RHN with the aim of inducing radiative masses for both active and sterile neutrinos¹.

In this work, we show that using a minimal content of leptoquarks to generate active neutrino masses, composed by one triplet and one singlet scalars, implies in generating light masses for the sterile states. As an original result, we show that active neutrinos acquire masses through one-loop and sterile neutrinos through two-loops, making sterile neutrinos, unavoidably, a light particle. To complete our study, we verify the implications of active neutrino mass and mixing, for different orderings, with some rare *B*- meson decays and the rare Higgs decay $h \rightarrow \mu^+ \tau^-$.

This paper is organized in the following way: In Sec. (II) we present the essence of the model including leptoquarks. In Sec. (III) we investigate the features of the loops that generate neutrino masses. In Sec. (IV) and (V) we investigate if light neutrinos are consistent with constraints from B-meson and rare Higgs decay physics. In Sec. (VI) we engage in discussions and conclude with a brief summary.

II. THE ESSENCE OF OUR FRAMEWORK

The leptonic sector of the 331RHN is composed by the standard leptons and right-handed neutrinos. This content is arranged into triplet and singlet according to the 3-3-1 symmetry transforming as [28, 29],

$$L_{a_{L}} = \begin{pmatrix} v_{a} \\ e_{a} \\ v_{a}^{c} \end{pmatrix}_{L} \sim (1, 3, -1/3), \quad e_{a_{R}} \sim (1, 1, -1), \tag{1}$$

with a = 1, 2 3 representing the three standard generations of leptons.

The hadronic sector is significantly different from the standard model[28, 29]. To achieve anomaly cancellation one family of quarks must transform differently from the other two. In this work we have chosen the first two families of quarks to transform as anti-triplet while the third

¹Leptoquarks were firstly introduced in the framework of 3-3-1 model in Ref. [33]. In the particular framework of the 331RHN leptoquarks were firstly introduced in Ref. [34]

one transforming as triplet under the 3-3-1 symmetry²,

$$Q_{i_{L}} = \begin{pmatrix} d_{i} \\ -u_{i} \\ d'_{i} \end{pmatrix}_{L}^{2} \sim (3, \bar{3}, 0), u_{i_{R}} \sim (3, 1, 2/3),$$

$$d_{i_{R}} \sim (3, 1, -1/3), \quad d'_{i_{R}} \sim (3, 1, -1/3),$$

$$Q_{3L} = \begin{pmatrix} u_{3} \\ d_{3} \\ u'_{3} \end{pmatrix}_{L}^{2} \sim (3, 3, 1/3), u_{3_{R}} \sim (3, 1, 2/3),$$

$$d_{3_{R}} \sim (3, 1, -1/3), u'_{3_{R}} \sim (3, 1, 2/3),$$

(2)

where the index i = 1, 2 is restricted to only two generations. The negative signal in the anti-triplet Q_{i_L} is to standardize the signals of the charged current interactions with the gauge bosons. The primed quarks are new heavy quarks with the usual $(+\frac{2}{3}, -\frac{1}{3})$ electric charges.

The original scalar sector of the model is composed by three triplets of scalars[28, 29]

$$\eta = \begin{pmatrix} \eta^0 \\ \eta^- \\ \eta'^0 \end{pmatrix}, \ \rho = \begin{pmatrix} \rho^+ \\ \rho^0 \\ \rho'^+ \end{pmatrix}, \ \chi = \begin{pmatrix} \chi^0 \\ \chi^- \\ \chi'^0 \end{pmatrix},$$
(3)

with η and χ transforming as (1, 3, -1/3) and ρ as (1, 3, 2/3).

The minimal content of leptoquarks required to achieve our goal include one triplet and one singlet of scalar leptoquarks transforming as,

$$T = \begin{pmatrix} T^{+1/3} \\ T^{-2/3} \\ T'^{+1/3} \end{pmatrix} \sim (3, 3, 0), \quad S^{+1/3} \sim (3, 1, 1/3)$$
(4)

To work with the simplest scenario, we impose the lagrangian of the model to be symmetric by a Z_2 symmetry with $(T, \eta, \rho, e_{a_R}, u_{a_R}, d_{a_R}) \rightarrow -(T, \eta, \rho, e_{a_R}, u_{a_R}, d_{a_R})$ while all the other fields transform trivially by the Z_2 symmetry.

With all this in hand, the Yukawa interactions among fermions and scalars in the model are composed by the following terms,

$$-\mathcal{L}_{Y} = \tilde{g}_{ij}\bar{Q}_{iL}\chi^{*}d'_{jR} + \tilde{h}_{33}\bar{Q}_{3L}\eta u'_{3R} + g_{ia}\bar{Q}_{iL}\eta^{*}d_{aR} + h_{3a}\bar{Q}_{3L}\eta u_{aR} + g_{3a}\bar{Q}_{3L}\rho d_{aR} + h_{ia}\bar{Q}_{iL}\rho^{*}u_{aR} + Y_{ab}\bar{L}_{aL}Td_{bR} + \tilde{Y}_{ia}\bar{Q}_{iL}^{C}L_{aL}S + y_{ab}\bar{u}_{aR}^{C}e_{bR}S + f_{aa}\bar{L}_{aL}\rho e_{aR} + \text{H.c.},$$
(5)

²For the other variants, see Refs.[35]

where a = 1, 2, 3 and i = 1, 2.

The potential of the model is composed by the terms

$$V(\eta, \rho, \chi, T, S) = V(\eta, \rho, \chi) + \mu_T^2 T^{\dagger} T + \mu_S^2 S^{\dagger} S + \tilde{\lambda}_1 |T^{\dagger} T|^2 + \tilde{\lambda}_2 |S^{\dagger} S|^2 + (\tilde{\lambda}_3 \eta^{\dagger} \eta + \tilde{\lambda}_4 \rho^{\dagger} \rho + \tilde{\lambda}_5 \chi^{\dagger} \chi) T^{\dagger} T + (\tilde{\lambda}_6 \eta^{\dagger} \eta + \tilde{\lambda}_7 \rho^{\dagger} \rho + \tilde{\lambda}_8 \chi^{\dagger} \chi) S^{\dagger} S + \tilde{\lambda}_9 |\eta^{\dagger} T|^2 + \tilde{\lambda}_{10} |\rho^{\dagger} T|^2 + \tilde{\lambda}_{11} |\chi^{\dagger} T|^2 + \tilde{\lambda}_{12} T^{\dagger} T S^{\dagger} S + (M T^{\dagger} \eta S + H.c.), \quad (6)$$

with $V(\eta, \rho, \chi)$ being the original scalar potential given in Refs. [36–39] while the parameter *M* is the energy scale associated to the explicit violation of lepton number. After spontaneous breaking of the 3-3-1 symmetry³, the resulting scalar spectrum involves five scalars (h_1 , h_2 , h_1^{\pm} , *A*) with mass at the electroweak scale and other five scalars (H, h_2^{\pm} , χ^0 , η'^0) with mass belonging to 3-3-1 scale[37, 39].

When η^0 develops VEV the last term in the potential promotes a mixing among the leptoquarks $T^{+1/3}$ and $S^{+1/3}$. Considering the basis $(S^{+1/3}, T^{+1/3})^T$ we get

$$M_{1/3}^{2} \approx \begin{pmatrix} \mu_{S}^{2} + \frac{1}{2} (\tilde{\lambda}_{6} v_{\eta}^{2} + \tilde{\lambda}_{7} v_{\rho}^{2} + \tilde{\lambda}_{8} v_{\chi'}^{2}) & \frac{M v_{\eta}}{\sqrt{2}} \\ \frac{M v_{\eta}}{\sqrt{2}} & \mu_{T}^{2} + \frac{1}{2} \left((\tilde{\lambda}_{3} + \tilde{\lambda}_{9}) v_{\eta}^{2} + (\tilde{\lambda}_{4} + \tilde{\lambda}_{10}) v_{\rho}^{2} + (\tilde{\lambda}_{5} + \tilde{\lambda}_{11}) v_{\chi'}^{2}) \right) \end{pmatrix}.$$
(7)

After diagonalize this mass matrix we obtain the eigenvalue M_1 associated to $\tilde{S}^{+1/3}$ and the eigenvalue M_2 associated to $\tilde{T}^{+1/3}$. The relation among the basis is given by

$$\begin{pmatrix} \tilde{S}^{+1/3} \\ \tilde{T}^{+1/3} \end{pmatrix} = \begin{pmatrix} C_{\theta} & -S_{\theta} \\ S_{\theta} & C_{\theta} \end{pmatrix} \begin{pmatrix} S^{+1/3} \\ T^{+1/3} \end{pmatrix},$$
(8)

with

$$\sin 2\theta = \sqrt{2} \frac{M v_{\eta}}{M_1^2 - M_2^2}.$$
(9)

The gauge sector of the model involves the standard gauge bosons plus one neutral gauge boson Z', two new charged gauge bosons W'^{\pm} and two non-hermitian neutral gauge bosons U^0 and $U^{0\dagger}$ [40]. All the new gauge bosons develop mass at $v_{\chi'}$ scale.

III. NEUTRINOS MASSES

In the original version of the 331RHN, neutrinos are massless [28, 29, 40]. A very versatile way of generating masses for the neutrinos is by introducing a sextet of scalars to the original scalar

$${}^{3}\langle\eta^{0}\rangle = v_{\eta} , \ \langle\rho^{0}\rangle = v_{\rho} , \ \langle\chi'^{0}\rangle = v_{\chi'} \text{ with } v_{\chi'} \gg v_{\eta} , \ v_{\rho} \text{ and } v_{\eta}^{2} + v_{\rho}^{2} = v_{ew}^{2}$$

FIG. 1. The left-handed neutrinos mass at one-loop (a) and right-handed neutrinos mass at two-loop (b).

content of the model. The sextet can enable the canonical type-I and type-II seesaw mechanisms [41–44]. Another possibility arises with the addition of new neutral chiral fermions, which can facilitate the inverse seesaw mechanism [45]. Radiative mass generation has also been explored in Refs. [46–49].

In most cases, right-handed neutrinos acquire masses significantly heavier than left-handed neutrinos. This result is expected since right-handed neutrinos are singlets under the Standard Model gauge symmetry. However, it is possible to arrange the model such that right-handed neutrinos can acquire light masses [30–32].

In this work, we propose and develop a novel mechanism for generating tiny neutrino masses within the 331RHN model, leveraging radiative corrections induced by leptoquarks. The relevant terms in the Yukawa Lagrangian, which contribute to neutrino mass generation, are proportional to the couplings Y and \tilde{Y} . By expanding these terms, we obtain

$$\bar{Q}_{i_{L}}^{C}L_{a_{L}}S \supset \bar{d}_{i_{L}}(v_{a_{L}})^{C}S^{*} + \bar{d}_{i_{L}}'v_{a_{R}}S^{*} = C_{\theta}\bar{d}_{b_{L}}(V_{L}^{d})_{bi}^{*}(v_{a_{L}})^{C}\tilde{S}^{-1/3} + S_{\theta}\bar{d}_{b_{L}}(V_{L}^{d})_{bi}^{*}(v_{a_{L}})^{C}\tilde{T}^{-1/3} + C_{\theta}\bar{d}_{i_{L}}'v_{a_{R}}\tilde{S}^{-1/3} + S_{\theta}\bar{d}_{i_{L}}'v_{a_{R}}\tilde{T}^{-1/3}$$
(10)

and

$$\bar{L}_{a_L}Td_{b_R} \supset \bar{d}_{b_R}v_{a_L}T^{-1/3} + \bar{d}_{b_R}(v_{a_R})^C T'^{-1/3} = C_\theta \bar{d}_{b_R}v_{a_L}\tilde{T}^{-1/3} - S_\theta \bar{d}_{b_R}v_{a_L}\tilde{S}^{-1/3} + \bar{d}_{b_R}(v_{a_R})^C \tilde{T'}^{-1/3}, (11)$$

where θ is the angle that transform $T^{1/3}$ and $S^{1/3}$ in the physical eigenstates $\tilde{T}^{1/3}$ and $\tilde{S}^{1/3}$. As we assumed that η'^0 is inert, consequently $T'^{1/3} = \tilde{T}'^{1/3}$, furthermore, let us consider $M_{T'^{1/3}} = M_2$.

The mixing matrix V_L^d transforms the flavor eigenstate d_L in the physical ones \hat{d}_L . Moreover they must respect the constraints $V_L^{\dagger d} V_L^u = V_{CKM}$. We also assume that d_R , u_R and $d'_{L,R}$ come in a diagonal basis. All this are common assumptions.

In this point we stress that the term $MT^{\dagger}\eta S^{1/3}$ in the potential in Eq. (6) is essential in obtaining neutrino masses since it violates lepton number by two units.

Before delving into the details, we note that the interactions described above lead to a very original result: left-handed neutrinos will acquire masses at the one-loop level, while right-handed neutrinos will acquire masses at the two-loops level. This predicts that sterile neutrinos are in-exorably light particles. The diagrams in the flavor basis illustrating the one-loop and two-loops processes generating neutrino masses are shown in FIG.1. We will develop each of these terms in detail below.

A. One-loop active neutrinos masses

The Yukawa interactions in Eqs. (10) and (11) can generate masses for the active neutrinos at the one-loop level, mediated by the leptoquarks \hat{T} and \hat{S} , as shown in FIG. 1(a). The resulting active neutrino mass matrix in the flavor basis is expressed as [50][51][52]

$$(m_{\nu})_{ab}^{L} = \frac{3}{16\pi^{2}} \sum_{i=1,2} \sum_{j=d,s,b} m_{j} B_{0}(0, m_{j}^{2}, M_{i}^{2}) \left(U_{i1}(\theta) U_{i2}(\theta) \left[(V_{L}^{d*} \tilde{Y})^{aj} Y^{jb} + (V_{L}^{d*} \tilde{Y})^{bj} Y^{ja} \right] \right),$$
(12)

where M_i^2 (*i* = 1, 2) are the mass eigenvalues of the leptoquarks, $U_{ij}(\theta)$ is the rotation matrix that diagonalizes the leptoquark mass basis, as defined in Eq.(7), and $B_0(0, m_j^2, M_i^2)$ is the Passarino-Veltman function, given by

$$B_0(0, m_j^2, M_i^2) = \frac{m_j^2 \ln(m_j^2) - M_i^2 \ln(M_i^2)}{m_j^2 - M_i^2}.$$
(13)

The matrix $(m_v)_{ab}^L$ must be consistent with the current constraints on the neutrino parameters [4]. Neglecting the CP phase of the neutrinos, the neutrino sector has five free parameters: three mixing angles, θ_{12} , θ_{13} , and θ_{23} , as well as two squared mass differences, Δm_{21}^2 and Δm_{31}^2 , which are required by solar and atmospheric neutrino oscillations. Imposing that $(m_v)_{ab}^L$, after diagonalized, recovers the current values of θ_{12} , θ_{13} , θ_{23} , Δm_{21}^2 and Δm_{31}^2 translates into a set of conditions on the parameters that define $(m_v)_{ab}^L$. Note that $(m_v)_{ab}^L$ given above involves much more free parameters than the necessary to recover uniquely the five free parameters responsible by the neutrino sector. Assuming that $m_{d,s,b}$ are much smaller than $M_{1,2}$ and that the up quarks come in a diagonal basis,

which means $V_L^d = V_{CKM}$, the Eq. (12) is opened in the following terms:

$$(m_{\nu})_{ab}^{L} = \frac{3}{32\pi^{2}} \sin 2\theta \ln \frac{M_{1}^{2}}{M_{2}^{2}} \sum_{p} \left(\begin{array}{c} m_{d} [(V_{\text{CKM}})_{ap} \tilde{Y}_{p1} Y_{1b} + (V_{\text{CKM}})_{bp} \tilde{Y}_{p1} Y_{1a}] + \\ m_{s} [(V_{\text{CKM}})_{ap} \tilde{Y}_{p2} Y_{2b} + (V_{\text{CKM}})_{bp} \tilde{Y}_{p2} Y_{2p}] + \\ m_{b} [(V_{\text{CKM}})_{ap} \tilde{Y}_{p3} Y_{3b} + (V_{\text{CKM}})_{bp} \tilde{Y}_{p3} Y_{3a}] \right),$$
(14)

In this work, we will study separately Normal Ordering (NO) and Inverted Ordering (IO) in order to investigate the impact of the neutrino mass ordering in the hadronic sector. For both orderings, the mixing angles θ_{12} , θ_{13} and the mass squared differences Δm_{solar}^2 , Δm_{atm}^2 are fixed by the bestfit values of NuFIT[4], while we are not adopting a preference for an octant of θ_{23} (sin² $\theta_{23} = 0.5$) and fixing to zero the CP phase (δ_{CP}).

For the oscillation data it is not possible to obtain the absolute mass of neutrinos, only the mass differences. Then, we are letting $m_1(m_3) = 0$, for NO(IO). For this choice, for NO, $m_2 = \sqrt{\Delta m_{solar}^2}$ and $m_3 = \sqrt{\Delta m_{atm^2}}$, while for the IO, $m_2 = \sqrt{\Delta m_{solar}^2} + \sqrt{\Delta m_{atm}^2}$ and $m_1 = \sqrt{\Delta m_{atm}^2}$, which implies that the heaviest active neutrino has mass ≈ 0.5 eV. To estimate the order of the Yukawa matrices \tilde{Y} and Y, we impose that Eq. (14) recover the full neutrino mass matrix in flavor basis. Then, we are solving a system with 6 equations with 12 variables (6 real variables for the components of each Yukawa matrix \tilde{Y} and Y). Assuming the above described values for the neutrino parameters and the quark masses and the CKM matrix from PDG[3] we solve the system

$$(m_{\nu})_{ab}^{L \ EXP} = (m_{\nu})_{ab}^{L \ PRED}$$
(15)

where $(m_v)_{ab}^{L EXP} = U_{PMNS}^T (m_v)^D U_{PMNS}$ with $m_v^D = diag(m_1 m_2, m_3)$. In this case $(m_v)_{ab}^{L EXP}$ represents the experimental value for the active neutrino mass matrix in flavor basis for each mass ordering and $(m_v)_{ab}^{L PRED}$ is the model prediction for the active neutrino mass at one loop. By solving the above sistem, it is possible to find the entries of the matrices Y and \tilde{Y} . For the NO case we have:

$$Y_{\rm NO} = \begin{pmatrix} 0.6728 & 0.1295 & -0.0031 \\ 0.1295 & 0.0236 & 0.0009 \\ -0.0031 & 0.0009 & -0.0019 \end{pmatrix}, \quad \tilde{Y}_{\rm NO} = \begin{pmatrix} 0.8822 & 0.0220 & 0.2103 \\ 0.0220 & -0.0237 & 0.0926 \\ 0.2103 & 0.0926 & 0.0032 \end{pmatrix}, \quad (16)$$

while for IO case we obtain:

$$Y_{\rm IO} = \begin{pmatrix} -0.6058 & -0.1263 & 0.0005 \\ -0.1263 & -0.0370 & 0.0052 \\ 0.0005 & 0.0052 & 0.0017 \end{pmatrix}, \quad \tilde{Y}_{\rm IO} = \begin{pmatrix} -0.4446 & 0.0756 & 0.1300 \\ 0.0756 & 0.2273 & 0.0695 \\ 0.1300 & 0.0695 & -0.0021 \end{pmatrix}. \tag{17}$$

In both cases the Yukawa couplings vary in the range $10^{-1} - 10^{-4}$ which are plausible values for these couplings. In short, we have active neutrino with mass at eV scale for very plausible values for the parameters involved in the neutrino mass expression as leptoquarks at TeV scale and Yukawa couplings within a range of values compatible with the values of the standard Yukawa couplings of the charged fermions in the SM. In other words, our model provides eV neutrinos in a conservative way.

B. Two-loop right-handed neutrinos masses

The Yukawa interactions in Eqs. (5), (10) and (11) yield inevitably to two-loops Majorana masses to the right-handed neutrinos as depicted in FIG.1(b). The loop is mediated by the standard singlet down quarks, d_R , the new quarks, d'_i , the leptoquarks $S^{1/3}$ and $T'^{1/3}$ and the scalar η'^0 . As d_R we assume that d'_i comes, too, in a diagonal basis. Thus, differently from the one loop case above of the standard neutrinos, the masses of the right-handed neutrinos will not involve the quarks mixing.

The expression to the sterile neutrino masses that arises from the loops in FIG. 1(b) is found in Refs. [52–56]. The respective resulting sterile neutrino mass matrix in the flavor basis can be written as

$$(m_{\nu})_{ab}^{R} = \frac{3M}{(2\pi)^{8}} \sum_{i=1,2} \sum_{j=d,s,b} m_{j} m_{d'_{i}} U_{11}(\theta) h(m_{d'_{i}}, M_{\eta'_{0}}, m_{j}, M_{S}, M_{T'}) \times \left[\tilde{Y}^{ai} g^{ip} Y^{pb} + \tilde{Y}^{bi} g^{ip} Y^{pa} \right] + \frac{3M}{(2\pi)^{8}} \sum_{i=1,2} \sum_{j=d,s,b} m_{j} m_{d'_{i}} U_{12}(\theta) h(m_{d'_{i}}, M_{\eta'_{0}}, m_{j}, M_{S}, M_{T'}) \times \left[\tilde{Y}^{ai} g^{ip} Y^{pb} + \tilde{Y}^{bi} g^{ip} Y^{pa} \right].$$

$$(18)$$

Before we proceed in determining $(m_v)^R$, let us make some observations: First, differently from the one-loop of the FIG. 1(a), in the two-loops in the FIG.1(b) only right-handed standard quarks

run into the loop which means we do not have the suppression factor due to quarks mixing $V_L^{u,d}$. In this expression the new quarks d'_{i_L} are naturally assumed in a diagonal basis. Note that as we commented below Eq.(5), the index i = 1, 2 is restricted to only two quarks generations. The factor M was introduced in Eq.(6) and generates the mixing between leptoquarks $S^{1/3}$ and $T^{1/3}$ which trigger the masses of the neutrinos. The leptoquark $T'^{1/3}$ carries 331 degrees of freedom and does not mix with leptoquarks $S^{1/3}$, $T^{1/3}$, as a consequence in Eq.(18), we have that sterile neutrino masses are proportional to $\cos \theta$ (or $\sin \theta$) and not to $\sin 2\theta$ as occurs at 1-loop level. In order to simplify even more our analysis we will assume that $m_{d'_i} \equiv m_{d'}$, and that all leptoquarks in the FIG.1(b) lies at the TeV scale, more precisely that these masses are of the same order as M_2 . In this case the integrals described in Eq.(18), can be written as $h(m_{d'}, M_{\eta'_0}, m_j, M_2)$ and we obtain

$$(m_{\nu})_{ab}^{R} = \frac{3Mm_{d'}}{(2\pi)^{8}} \sum_{i=1,2} \sum_{j=d,s,b} m_{j}h(m_{d'}, M_{\eta'_{0}}, m_{j}, M_{2}) \left[\tilde{Y}^{ai}g^{ip}Y^{pb} + \tilde{Y}^{bi}g^{ip}Y^{pa} \right].$$
(19)

Since that all quarks in the loop are in a diagonal basis, we have

$$(m_{\nu})_{ab}^{R} = \frac{3Mm_{d'}m_{b}}{(2\pi)^{8}} \sum_{i=1,2} \left(g_{i1}\frac{m_{d}}{m_{b}}h(m_{d'}, M_{\eta'_{0}}, m_{d}, M_{2}) \left[\tilde{Y}^{ai}Y^{1b} + \tilde{Y}^{bi}Y^{1a} \right] + g_{i2}\frac{m_{s}}{m_{b}}h(m_{d'}, M_{\eta'_{0}}, m_{s}, M_{2}) \left[\tilde{Y}^{ai}Y^{2b} + \tilde{Y}^{bi}Y^{2a} \right] + g_{i3}h(m_{d'}, M_{\eta'_{0}}, m_{b}, M_{2}) \left[\tilde{Y}^{ai}Y^{3b} + \tilde{Y}^{bi}Y^{3a} \right] \right)$$
(20)

Therefore, assuming that $m_b \gg m_d, m_s$, the maximum contribution to $(m_v)_{ab}^R$ can be identified as

$$(m_{\nu})_{ab}^{R} = \frac{3Mm_{d'}m_{b}}{(2\pi)^{8}}h(m_{d'}, M_{\eta_{0}'}, m_{b}, M_{2})\sum_{i=1,2}g_{i3}\left[\tilde{Y}^{ai}Y^{3b} + \tilde{Y}^{bi}Y^{3a}\right].$$
(21)

such that $h(m_{d'}, M_{\eta'_0}, m_b, M_2)$ is given in Appendix A.

By fixing $M_2 = 2$ TeV, we obtain the value of M = 147 GeV for $\sin 2\theta = 10^{-2}$. For the other typical 3-3-1 particles, we fix $m_{d'} = 1$ TeV and $M_{\eta'_0} = 3$ TeV. Moreover for $v_{\eta} = v_{\rho}$ we obtain $g_{13} = 0.000119$ and $g_{23} = 0.0014$. For these benchmark points, it is possible to estimate the value of the sterile neutrinos masses for NO and IO discussed above for the standard neutrinos. This is a peculiar feature of the 331RHN since left-handed and right-handed neutrinos compose the same lepton triplet then they share the same Yukawa interactions with the leptoquarks. In this way the Yukawa couplings that compose the mass matrix of the left-handed neutrinos will appear in the mass matrix of the right-handed neutrinos. Thus we would like to see what profile the NO and IO

benchmark points for the left-handed neutrinos discussed above infer on the on the right-handed neutrinos.

For the values of the Yukawa couplings associated to the NO case discussed above, the model predicts, $m_1^R \approx 0$, $m_2^R \approx 19$ eV and $m_3^R \approx 24$ eV, while for the case of IO, the model predicts $m_3^R \approx 0$, $m_1^R \approx 1$ eV and $m_2^R \approx 50$ eV. In both cases right-handed neutrinos have masses at eV scale. This is curious because they acquire mass via two-loops process. We can understand this looking in the mass expression above. In it we do not have the surppresion factors V_{CKM} and $\sin(2\theta)$. Instead we have enhance factors as M and $m_{d'}$.

Note that, although these sterile neutrinos do not mix with the active ones, therefore they do not participate in any short-baseline, reactor and accelerator neutrinos experiments. However, even in this case, they still interact with the standard fermions. These interactions are mediated by the new gauge bosons of the 3-3-1 model and by the leptoquarks. Because they are light neutrinos, their natural source of constraints are derived from their contributions to cosmological and astrophysical observables as N_{eff} , bounds from BBN and CMB anisotropies, etc. Nevertheless, the Yukawa interactions among leptoquarks and fermions will give contributions to some B-meson decays and also lead to rare Higgs decay. Next we check if the scenario we develop in this section is in agreement with such processes⁴.

IV. B-MESON PHYSICS

In this section we check if the parameter space of the Yukawa leptoquarks given in Eqs. (16) and (17) together with leptoquarks with mass around 2 TeV are in agreement with the physics of the B-meson.

A. The contributions to $B \rightarrow \mu^+ \mu^-$ decay

The rare decay $B_s \rightarrow \mu^+ \mu^-$ is a key process for probing New Physics (NP) at the LHC, as it provides some of the strongest bounds on deviations from the Standard Model (SM) due to its precise theoretical prediction [57, 58]. The 331 leptoquarks (331LQ) contributions to this process can be extract from the Yukawa interaction

$$\mathcal{L} \supset Y^{ab} \bar{d}_{aR} e_{bL} T^{+2/3} + h.c.$$
⁽²²⁾

⁴The cosmological and astrophysical implications will be investigated elsewhere

FIG. 2. Feynman diagram contribution to $B_s \rightarrow \mu^+ \mu^-$ decay for 331LQ model.

and be represented by the diagram showed in the FIG. 2. The scalar leptoquark interactions via quark-leptoquark penguin diagrams that potentially contribute to this process in our model are depicted in the FIG.5.

In the SM, the effective Hamiltonian relevant to $b \rightarrow s\mu^+\mu^-$ decay can be written as[59][60]

$$H_{eff} = -\frac{4G_F}{\sqrt{2}} V_{tb} V_{ts}^* \left[\sum_{i=1}^6 C_i O_i + \frac{\alpha C_7}{4\pi} (\bar{s}\sigma_{\mu\nu}(m_s P_L + m_b P_R) b) F^{\mu\nu} + \frac{\alpha C_9}{4\pi} (\bar{s}\gamma^{\mu} P_L b) (\bar{l}\gamma_{\mu} l) + \frac{\alpha C_{10}}{4\pi} (\bar{s}\gamma^{\mu} P_L b) (\bar{l}\gamma_{\mu}\gamma_5 l) \right],$$
(23)

where in this expression $V_{tb}V_{ts}^*$ are CKM matrix elements, $\alpha = \frac{e^2}{4\pi}$ is the fine structure constant, the chiral projectors are $P_{L,R} = \frac{1}{2}(1 \pm \gamma_5)$ and C_i to i = 1..10, are the Wilson coefficients. Below, we list the operators indicated in Eq.(23), as well as the list of other operators susceptible to leptoquarks effects considered in this work

$$O_7 = \frac{\alpha}{4\pi} (\bar{s}\sigma_{\mu\nu}(m_s P_L + m_b P_R)b)F^{\mu\nu} , \quad O_9 = \frac{\alpha}{4\pi} (\bar{s}\gamma^{\mu} P_L b)(\bar{l}\gamma_{\mu}l)$$
(24)

$$O_{10} = \frac{\alpha}{4\pi} (\bar{s}\gamma^{\mu} P_L b) (\bar{l}\gamma_{\mu}\gamma_5 l) \qquad , \quad O_S = \frac{\alpha}{4\pi} (\bar{s}\gamma^{\mu} P_R b) (\bar{l}l) \qquad (25)$$

$$O_P = \frac{\alpha}{4\pi} (\bar{s}\gamma^{\mu} P_R b)(\bar{l}\gamma_5 l) \qquad , \quad O_T = \frac{\alpha}{4\pi} (\bar{s}\sigma_{\mu\nu} b)(\bar{l}\sigma^{\mu\nu} l) \qquad (26)$$

$$O_{T5} = \frac{\alpha}{4\pi} (\bar{s}\sigma_{\mu\nu}b)(\bar{l}\gamma_5\sigma^{\mu\nu}l).$$
⁽²⁷⁾

The effective Hamiltonian described by Eq.(23) will receive corrections due to leptoquark interactions described in the Eq.(22). Considering the Fierz transformation listed in Appendix B, we can estimate the correction given by the interactions in Eq. (22) to $b \rightarrow s\mu^+\mu^-$ decays. The effective 331LQ Hamiltonian that matter is given by

$$H^{331LQ} = \frac{Y^{32}Y^{22}}{8M_T^2} (\bar{s}\gamma^{\mu}(1+\gamma_5)b)(\bar{\mu}\gamma_{\mu}(1-\gamma_5)\mu)$$

$$\equiv \frac{Y^{32}Y^{22*}}{4M_T^2} (O_{9'} - O_{10'}), \qquad (28)$$

where we assume for simplicity $M_T \approx M_2$. Note that the set of operators with "primes", $O_{9'}$ and $O_{10'}$, are related to the "unprimed" set by switching the roles of P_L and P_R .

In order to estimate the corrections to the effective operators in the Eq.(23), we can write the analogous to the Standard Model counterpart in the form

$$H^{331LQ} = -\frac{G_F \alpha}{\pi \sqrt{2}} V_{tb} V_{ts}^* (C_{9'} O_{9'} + C_{10'} O_{10'}), \tag{29}$$

which allows the identification of the new Wilson coefficients $C_{9'}$ and $C_{10'}$ associated with the operators $O_{9'}$ and $O_{10'}$

$$C_{10'} = -C_{9'} = \frac{Y^{32}Y^{22*}}{2\sqrt{2}G_F\alpha V_{tb}V_{ts}^*}\frac{\pi}{M_T^2}.$$
(30)

Assuming the effective theory given by Eq.(23),in the SM the only operator contributing to $B_s \rightarrow \mu^+ \mu^-$ amplitude is the $O_{10}[61]$, and the expression for the branching fraction of this decay can be write as

$$\mathbf{B}_{\mathbf{r}}^{s_{\mathcal{M}}}(B_{s} \to \mu^{+}\mu^{-}) = \frac{N^{B}}{\pi} m_{B_{s}} \beta_{\mu}(m_{B_{s}}^{2}) |C_{10}|^{2}$$
(31)

where we define

$$N^{B} \equiv \tau_{B_{s}} \left(\frac{G_{F}\alpha |V_{tb}V_{ts}^{*}|}{4\pi}\right)^{2} m_{\mu}^{2} f_{B_{s}}^{2}$$

$$\beta_{\mu}(m_{B_{s}}^{2}) \equiv \sqrt{1 - 4m_{\mu}^{2}/m_{B_{s}}^{2}},$$
(32)

and in this expression f_{B_s} is the B_s meson decay constant. However, as discussed in Ref.[62], the average time integrated branching ratio $\overline{\text{Br}}(B_s \to \mu^+ \mu^-)$ depend on the details of $\overline{B_s} - B_s$ mixing, which in the SM are related to the decay widths $\Gamma(B_s \to \mu^+ \mu^-)$ by a very simple relation obtained in these reference, $\overline{\text{Br}}(B_s \to \mu^+ \mu^-) = \Gamma(B_s \to \mu^+ \mu^-)/\Gamma_H^s$, where Γ_H^s is the total width of the heaviest mass eigenstate.

The current SM prediction for these branching ratio corresponds to [63]

$$\overline{\mathrm{Br}}^{^{SM}}(B_s \to \mu^+ \mu^-) = (3.64 \pm 0.12) \times 10^{-9}, \tag{33}$$

and the current world average stands for[64]

$$\overline{\mathrm{Br}}^{exp}(B_s \to \mu^+ \mu^-) = (3.34 \pm 0.27) \times 10^{-9}, \tag{34}$$

The 331LQ contributions to the corresponding branching ratio is given as

$$B_{r}^{331LQ}(B_{s} \to \mu^{+}\mu^{-}) = \frac{N^{B}}{\pi} m_{B_{s}} \beta_{\mu}(m_{B_{s}}^{2}) |C_{10} - C_{10'}|^{2}, \qquad (35)$$

taking over corrections discussed in the paragraph above, considering Eqs.(31-35) as well as $C_{10'}$ given be Eq.(30), assuming the current experimental limit() we obtain the following constraints on leptoquark couplings as

$$0 \lesssim \frac{|Y^{32}Y^{22*}|}{M_T^2} \lesssim 1.37 \times 10^{-9} \,\text{GeV}^{-2}.$$
(36)

For leptoquarks at TeV scale ($M_T \approx 1 - 2$ TeV) we obtain the lower bound $|Y^{32}Y^{22*}| < 1.37 \times 10^{-3}$. Our illustrative case in Eqs. (16) and (17) respect such bound.

B. The contributions to $b_R \rightarrow s_R v_L v_L$ decay

The correlations between $B(B \to K\nu\nu)$ and $B(B \to K^*\nu\nu)$ provide important insights into the possible contributions of New Physics (NP) to the effective operators governing these rare decays. Both channels are mediated by the $b \to s\nu\bar{\nu}$ transition, which is highly suppressed in the Standard Model (SM) due to loop-level processes and small effective couplings.

In the SM, the relation between these branching ratios is well-defined, with $B(B \rightarrow K^* \nu \nu)$ expected to be larger due to the additional degrees of freedom from the K^* polarization states.

The Belle II experiment recently observed the decay $B^+ \rightarrow K^+ + \text{inv}$ with a measured branching ratio [65]:

$$B(B^+ \to K^+ + inv)_{exp} = (2.3 \pm 0.7) \times 10^{-5},$$

exceeding the SM prediction [66]:

$$B(B^+ \to K^+ \nu \nu)_{SM} = (4.44 \pm 0.30) \times 10^{-6}$$

This 2.7 σ discrepancy has sparked interest in NP scenarios, including effective field theories and dark sector particles. From the other side, Belle imposed a superior bound on the decay $B^+ \rightarrow K^*$ + inv at 90% C.L. [67]. Thus, due to the large correlation between *K* and K^* , not all effective operators generated by NP can alleviate the tension, and sometimes they could even increase it[68]. This is why this section is dedicated to analyzing the correlation between *K* and K^* decays into the 331LQ model.

FIG. 3 represents the Feynman diagram of the main contribution of the 331LQ to the decay of *B* into $K^{(*)}\nu\nu$. The interactions in the flavor basis that lead to this process are

$$Y_{ab}\bar{v}_{bL}d_{a_R}T^{1/3} + \tilde{Y}_{ai}\bar{v}_{a_L}(d_{i_L})^C S^{1/3} + \frac{Mv_{\eta}}{\sqrt{2}}T^{+1/3}S^{-1/3},$$
(37)

FIG. 3. Feynman diagram contribution to $b \rightarrow sv_L \bar{v}_L$ decay in 331LQ model.

where this contribution is represented by the diagram FIG.3. In the physical basis we have

$$Y_{ab}\bar{\hat{v}}_{pL}(U_{PMNS})_{pb}\hat{d}_{aR}(C_{\theta}\tilde{T}^{1/3} - S_{\theta}\tilde{S}^{1/3}) + \tilde{Y}_{ai}\bar{\hat{v}}_{pL}(U_{PMNS})_{ap}(V_{L}^{d})_{bi}\hat{d}_{bR}(C_{\theta}\tilde{S}^{1/3} + S_{\theta}\tilde{T}^{+1/3})$$
(38)

From the interaction described above, we get the following effective operator

$$\mathcal{M}_{p,p'}^{q^2 \to 0} = \sum_{a,a',i=1}^{3} \frac{\sin 2\theta \, Y_{a3}(V_L^d)_{2i} \tilde{Y}_{a'i} U_{p'a'}^{PMNS} * U_{ap}^{PMNS} (M_2^2 - M_1^2)}{8M_1^2 M_2^2} (\bar{s}_R \nu_{Lp}) (\bar{\nu}_{Lp'} b_R), \tag{39}$$

such that the indices p, p' varies between 1 to 3, representing the flavor basis of the neutrinos in the interaction. From these operators, after a Fierz transformation, it is possible to write the relevant effective Hamiltonian of 331LQ contributions to $b \rightarrow sv_L\bar{v}_L$:

$$H_{331LQ}^{\nu} = \frac{G_F \alpha}{2\sqrt{2}\pi} V_{tb} V_{ts}^* \sum_{p,p'} (C_{9'}^{p,p'} O_{9'}^{p,p'} + C_{10'}^{p,p'} O_{10'}^{p,p'}),$$
(40)

with the Wilson coefficients $C_{9'}$ and $C_{10'}$ given by

$$C_{9'}^{p,p'} = \frac{\pi \sin 2\theta \, Y_{a3}(V_L^d)_{2i} \tilde{Y}_{a'i} U_{p'a'}^{PMNS *} U_{ap}^{PMNS} (M_2^2 - M_1^2)}{2 \, \sqrt{2} G_F \alpha V_{lb} V_{ls} M_1^2 M_2^2} = -C_{10'}^{p,p'} \tag{41}$$

where θ is the angle that rotate $T^{1/3}$ and $S^{1/3}$ in the physical eigenstates.

In FIG. 4, the correlation between $B(B \to Kvv)$ and $B(B \to K^*vv)$ is analyzed, considering the impact of contributions from 331LQ to New Physics (NP) operators using the formula of [68]. The red point represents the Standard Model (SM) prediction, while the (light) green regions indicate the Belle II results at $1(2)\sigma$. The hatched gray areas correspond to the Belle upper bound, $B(B \to K^*vv) < 2.5 \times 10^{-5}$ [67]. Using the benchmark points for the NO and IO scenarios, along with the previously discussed benchmarks, the contribution to the SM prediction exhibits a negligible correction, on the order of 10^{-5} . This small correction can be attributed to the fact that Y_{a3} is always of the order of 10^{-3} , while the dominant term in the product $(V_L^d)_{2i}\tilde{Y}_{a'i}$ is proportional to 10^{-1} . Consequently, we find that

$$C_{9'} \approx -10^5 \frac{\sin 2\theta (M_1^2 - M_2^2)}{M_1^2 M_2^2} \to C_{9'} \approx -10^{-2} \sin 2\theta \frac{(1 \text{ TeV})^2}{M_2^2},$$
 (42)

FIG. 4. Correlation between $B(B \to K\nu\nu)$ and $B(B \to K^*\nu\nu)$ when including the effect of the contributions of 331LQ to New Physics (NP) operators using the formula of [68]. The red point corresponds to the SM result and the (light) green regions to the Belle II result at $1(2)\sigma$ [65]. The hatched gray areas on the panel correspond to the Belle upper bound, $B(B \to K^*\nu\nu) < 2.5 \times 10^{-5}$ [67].

while assuming $M_1 = 1.3M_2$.

For $C_{9'}$ to be relevant, it must satisfy the condition $|C_{9'}| > |C_L^{SM}| \approx 6[68]$, where C_L^{SM} represents the SM Wilson coefficient for the same process. According to our finding in Eq. (42), we have $C_{9'} < 10^{-2}$, indicating that the contribution from leptoquarks alone does not account for the experimental result observed by Belle II collaboration. However, the 331RHN includes additional contributions to such processes mediated by neutral scalars and the gauge boson Z' that, potentially, may accommodate Belle II collaboration result. This will be checked elsewhere.⁵

⁵Our proposal here is just to check the contributions from leptoquarks alone in order to check if they enter in conflict with existent experimental results.

FIG. 5. Feynman diagrams for 331LQ contributions to $h \rightarrow \tau \mu$ decay.

V. RARE HIGGS DECAY

In the Standard Model (SM), flavor-violating (FV) Higgs interactions are highly suppressed [69, 70]. However, the ATLAS Collaboration has recently reported an excess in the search for the decay $h \rightarrow \tau \mu$ [71]. In our model, scalar leptoquark interactions can contribute to this process via quark-leptoquark penguin diagrams, as illustrated in FIG. 5. These diagrams involve a helicity flip on one of the fermion lines, which is essential for generating the amplitude.

The relevant interactions from those presented in Eq. (5) that lead to this process are the Yukawa couplings involving scalar leptoquarks and fermions. These couplings mediate flavor-violating transitions via loop-level diagrams, such as quark-leptoquark penguin diagrams shown in FIG. 5. In particular, terms where leptoquarks couple to both quarks and leptons play a critical role in inducing the $h \rightarrow \tau \mu$ decay. These interactions provide the necessary helicity flip on the fermion line to generate the amplitude for this rare process [56, 69]

$$\mathcal{L} \supset \bar{u}_a^c (\tilde{Y}_{ia} P_L + y_{ab} P_R) e_b \tilde{S}^{1/3} + H.c,$$
(43)

After the explicit computation of the penguin diagrams, that can be found in Refs.[72][73], the

331LQ contributions to the effective $\mu - \tau - h$ coupling take the form

$$y_{(\mu\tau)}^{\tau\mu} = -\frac{3}{16\pi^2} \frac{m_t}{v} f_1(\lambda, M_2)(\tilde{Y}_{33}y_{32})(\tilde{Y}_{32}y_{33}), \tag{44}$$

where for reasons of simplification, and without any loss for the model, we consider that charged leptons, neutrinos, right-handed quarks and the new quarks come in a diagonal basis[34].

The Higgs portal coupling, as defined in Ref.[72], is given in our case as,

$$\mathcal{L} \supset -(\tilde{\lambda}_6 + \tilde{\lambda}_7) vhS^{\dagger}S \equiv -\lambda vhS^{\dagger}S,$$

where we have made the usual assumptions: $v_{\eta} = v_{\rho} = \frac{v}{\sqrt{2}}$ with $h = \frac{R_{\eta}}{\sqrt{2}} + \frac{R_{\rho}}{\sqrt{2}}$ playing the role of the standard Higgs. The function $f_1(\lambda, M_2)$ is the one-loop function given by

$$f_1(\lambda, M_2) = (M_2^2 + m_t^2)C_0(0, 0, m_h^2, m_t^2, M_2^2, m_t^2) + B_0(m_h^2, m_t^2, m_t^2) + B_0(0, m_t^2, M_2^2) + \lambda v^2 C_0(0, 0, m_h^2, M_2^2, m_t^2, M_2^2),$$
(45)

such that (B_0, C_0) are the Passarino-Veltman functions, where $B_0(0, m_t^2, M_2^2)$ has an analytical expression analogous to Eq. (13). With these components at hand, we now have all the necessary elements to compute the decay width for the $h \rightarrow \tau \mu$ process.

The $h \rightarrow \tau \mu$ partial decay width in our model stands for

$$\Gamma(h \to \tau \mu) = \frac{9m_h m_t^2}{2^{13} \pi^5 v^2} F^2(\tilde{Y}) |f_1(\lambda, M_2)|^2,$$
(46)

such that $F^2(\tilde{Y}) \equiv |\tilde{Y}_{33}y_{32}|^2 + |\tilde{Y}_{32}y_{33}|^2$.

In this section, we investigate the contributions from leptoquarks to the process $h \rightarrow \tau \mu$. As discussed in Ref. [74], the introduction of scalar leptoquarks into the 331RHN model provides a solution to the $(g - 2)_{\mu}$ puzzle. By comparing with the experimental results for $(g - 2)_{\mu}$, we derived a bound on the parameter space, specifically $y_{32} \leq 0.5$. For the coupling \tilde{Y} , we utilize the benchmark points provided in Eqs. (16) and (17) for the normal ordering (NO) and inverted ordering (IO) cases, while the parameter y_{33} remains free, constrained only by the perturbativity limit $(y_{33} \leq 4\pi)$.

In addition, we assume $M_{LQ} = 2$ TeV and $y_{33} \approx 1$. With these parameters, we predict the branching ratio for the $h \rightarrow \tau \mu$ decay as follows:

$$Br^{331LQ}(h \to \tau\mu) = 1.56 \times 10^{-4} \%.$$
(47)

The current limit established by the ATLAS Collaboration for this branching ratio is [75, 76]:

$$Br^{\text{ATLAS}}(h \to \tau \mu) = 0.37^{+0.14}_{-0.10} \%.$$
(48)

As seen above, the predicted branching ratio $Br^{331LQ}(h \rightarrow \tau \mu)$ is consistent with the current limit established by the ATLAS Collaboration.

VI. SUMMARY AND CONCLUSION

In the original version of the 3331RHN model, neutrinos are massless particles. Numerous attempts have been made to generate small masses for the neutrinos within the 331RHN model. However, the majority of the attempts are based on seesaw mechanisms. In this paper we focused on radiative corrections. A particulary interesting and efficient scenario for generating radiative neutrino masses is one based on leptoquarks. We, then, added the most economical set of leptoquarks to the 331RHN that is capable of generating small masses for the standard neutrinos. The leptoquark content encompasses a triplet, T, and a singlet, S, of scalar leptoquarks. This content attended efficiently our goal and standard neutrinos acquired masses through one-loop corrections and sub-eV neutrino mass was obtained for leptoquarks at TeV scale.

In the 331RHN model, right-handed neutrinos, along with the standard leptons, form the triplet of leptons. The Yukawa interactions that generate masses for the standard neutrinos also generate masses for the right-handed neutrinos. As interesting results, right-handed neutrinos acquired masses via two-loops corrections, making them, inexorably, light particles. It is important to emphasize that, even though right-handed neutrinos acquired masses at two-loop level, in our illustrative scenario, considering both NO and IO cases, they still became slightly heavier than the standard neutrinos. This occurred because the masses of these neutrinos are proportional to the heavy particles of the model, which is sufficient to enhance their masses beyond those of the standard neutrinos.

A notable aspect of the 331LQ model concerning neutrino masses is that it does not induce mixing among right-handed and left-handed neutrinos. Consequently right-handed neutrinos are free from short-baseline neutrinos experimental constraints. Although these right-handed neutrinos are sterile neutrinos, they interact with standard fermions via the new gauge bosons of the 331LQ model rendering them susceptible to cosmological and astrophysical constraints.

We also examined whether the benchmark points in Eqs. (16) and (17) satisfy *B*-meson observables and rare Higgs decays constrainst. Regarding *B*-meson physics, we verified that the prediction of the model to $B \rightarrow \mu^+\mu^-$ and the correlations between $B(B \rightarrow K\nu\nu)$ and $B(B \rightarrow K^*\nu\nu)$ decay are consistent with current experimental results. In the Higgs decay inducing LFV, we verified that the benchmark points in Eqs. (16) and (17), in conjuction with (g - 2) solution, easily comply the bounds originating from $h \rightarrow \tau \mu$ decay imposed by ATLAS collabration.

All our findings indicate that the 331LQ model we have presented and developed here is both economic and efficient in generating small masses for the neutrinos. Moreover this scenario has as signature leptoquarks with masses at TeV scale that are being probed currently at the LHC.

Appendix A: Two-loop parameters

The function h in Eq.(21) is defined according

$$h(M_{d'}, M_{\eta'_0}, m_b, M_2) = 4 \int d^4 p \int d^4 k \frac{1}{(p^2 - M_2^2)} \frac{1}{(p^2 - m_{d'_i}^2)} \\ \times \frac{1}{(k^2 - M_2^2)} \frac{1}{(k^2 - m_b^2)} \frac{1}{((p - k)^2 - M_{\eta'_0}^2)},$$
(A1)

after performing a Wick rotation, the integral above can be written as follows[54]

$$h(m_{d'_i}, M_{\eta'_0}, m_b, M_2) = \frac{8}{(M_2^2 - m_{d'}^2)} \frac{1}{(M_2^2 - m_b^2)} \sum_{s=1}^3 f_s(m_{d'}, M_{\eta'_0}, M_2, m_b)$$
(A2)

where $m_{d'_i} \equiv m_{d'}$ is the mass of the new quark d type relevant to the 331RHN mass scale μ_{331} , m_b is the bottom quark mass. As we commented all leptoquarks in the FIG.1(b) lie in the TeV scale characterized by M_2 . In the expression A2 the functions $f_s(m_{d'_i}, M_{\eta'_0}, M_2, m_b)$, to s = 1..3 are

$$f_1(m_{d'}, M_{\eta'_0}, M_2, m_b) = \pi^4 m_{d'}^2 \left(F(a_1, b_1) - F(a_2, b_2) \right) + \pi^4 m_b^2 \left(F(a_3, b_3) - F(a_4, b_4) \right)$$

$$f_2(m_{d'}, M_{\eta'_0}, M_2, m_b) = \pi^4 M_{\eta'_0}^2 \left(F(a_5, b_5) + F(a_6, b_6) - F(a_7, b_7) - F(a_8, b_8) \right)$$

$$f_3(m_{d'}, M_{\eta'_0}, M_2, m_b) = \pi^4 M_2^2 \left(F(a_9, b_9) + F(a_{10}, b_{10}) - 2F(a_{11}, b_{11}) \right).$$
(A3)

and the auxiliary functions $F(a_i, b_i)$, with i = 1..11, are defined by

$$F(a_i, b_i) = \int_0^1 dx \left(Li_2(1 - \mu_i^2) - \frac{\mu_i^2 \log(\mu_i^2)}{1 - \mu_i^2} \right)$$
(A4)

in which

$$\mu_i^2 = \frac{a_i x + b_i (1 - x)}{x(1 - x)},\tag{A5}$$

and $Li_2(x)$ is the dilogarithm function defined as

$$Li_{2}(x) = -\int_{0}^{x} dy \frac{\log(1-y)}{y}.$$
 (A6)

The respective (a_i, b_i) coefficients listed in Eq.(A3) are defined according to

$$a_{1} = \left(\frac{M_{2}}{m_{d'}}\right)^{2}, \ a_{2} = \left(\frac{m_{b}}{m_{d'}}\right)^{2}, \ b_{1} = b_{2} = \left(\frac{M_{\eta'_{0}}}{m_{d'}}\right)^{2}$$

$$a_{3} = \left(\frac{M_{2}}{m_{b}}\right)^{2}, \ a_{4} = \left(\frac{m_{d'}}{m_{b}}\right)^{2}, \ b_{3} = b_{4} = \left(\frac{M_{\eta'_{0}}}{m_{b}}\right)^{2}$$

$$a_{5} = \left(\frac{M_{2}}{M_{\eta'_{0}}}\right)^{2}, \ b_{5} = \left(\frac{m_{b}}{M_{\eta'_{0}}}\right)^{2}, \ b_{6} = a_{8} = b_{8} = \left(\frac{M_{2}}{M_{\eta'_{0}}}\right)^{2}$$

$$a_{9} = \left(\frac{m_{b}}{M_{2}}\right)^{2}, \ b_{7} = \left(\frac{m_{b}}{M_{\eta'_{0}}}\right)^{2}, \ b_{9} = b_{10} = b_{11} = \left(\frac{M_{\eta'_{0}}}{M_{2}}\right)^{2}$$

$$a_{10} = \left(\frac{m_{d'}}{M_{2}}\right)^{2}, \ a_{6} = a_{7} = \left(\frac{m_{d'}}{M_{\eta'_{0}}}\right)^{2}, \ a_{11} = 1.$$
(A7)

Appendix B: Fierz transformation

The effective operator $(\bar{\chi}_R \Psi_L)(\bar{\Psi}_L \chi_R)$ can be written in the form

$$(\bar{\chi}_R \Psi_L)(\bar{\Psi}_L \chi_R) = \frac{1}{4} ((\bar{\chi} \Psi)(\bar{\Psi}\chi) - (\bar{\chi}\gamma_5 \Psi)(\bar{\Psi}\gamma_5 \chi))$$
(B1)

Assuming the product of bilinear spinors decomposed in the Fierz base according to

$$(\bar{\chi}\Psi)(\bar{\Psi}\chi) = \frac{1}{4}(\bar{\chi}\chi)(\bar{\Psi}\Psi) + \frac{1}{4}(\bar{\chi}\gamma^{\mu}\chi)(\bar{\Psi}\gamma_{\mu}\Psi) + \frac{1}{8}(\bar{\chi}\eta^{\mu\nu}\chi)(\bar{\Psi}\eta_{\mu\nu}\Psi) + \frac{1}{4}(\bar{\chi}\gamma^{\mu}\gamma_{5}\chi)(\bar{\Psi}\gamma_{\mu}\gamma_{\Psi}) + \frac{1}{4}(\bar{\chi}\gamma_{5}\chi)(\bar{\Psi}\gamma_{5}\Psi)$$
(B2)

$$(\bar{\chi}\gamma_5\Psi)(\bar{\Psi}\gamma_5\chi) = \frac{1}{4}(\bar{\chi}\chi)(\bar{\Psi}\Psi) - \frac{1}{4}(\bar{\chi}\gamma^{\mu}\chi)(\bar{\Psi}\gamma_{\mu}\Psi) + \frac{1}{8}(\bar{\chi}\eta^{\mu\nu}\chi)(\bar{\Psi}\eta_{\mu\nu}\Psi) + \frac{1}{4}(\bar{\chi}\gamma^{\mu}\gamma_5\chi)(\bar{\Psi}\gamma_{\mu}\gamma_5\Psi) + \frac{1}{4}(\bar{\chi}\gamma_5\chi)(\bar{\Psi}\gamma_5\Psi)$$
(B3)

Considering Eqs.(B2) and (B3) we can write Eq.(B1) as

$$(\bar{\chi}_R \Psi_L)(\bar{\Psi}_L \chi_R) = \frac{1}{8} ((\bar{\chi} \gamma^\mu \chi)(\bar{\Psi} \gamma_\mu \Psi) - (\bar{\chi} \gamma^\mu \gamma_5 \chi)(\bar{\Psi} \gamma_\mu \gamma_5 \Psi))$$
$$= \frac{1}{8} ((\bar{\chi} \gamma^\mu (1 + \gamma_5) \chi)(\bar{\Psi} \gamma_\mu (1 - \gamma_5) \Psi).$$
(B4)

The Fierz transformations are typically straightforward for orthogonal operators, like scalarscalar and vector-vector operators. However, for non-orthogonal operators, such as scalar-pseudo scalar operators, the transformation is more complex due to the different nature of these operators. In these case we have

$$\begin{split} (\bar{\chi}\Psi)(\bar{\Psi}\gamma_5\chi) &= \frac{1}{4}(\bar{\chi}\chi)(\bar{\Psi}\gamma_5\Psi) + \frac{1}{4}(\bar{\Psi}\Psi)(\bar{\chi}\gamma_5\chi) + \frac{1}{4}(\bar{\chi}\gamma^{\mu}\chi)(\bar{\Psi}\gamma_{\mu}\gamma_5\Psi) - \frac{1}{4}(\bar{\chi}\gamma^{\mu}\gamma_5\chi)(\bar{\Psi}\gamma_{\mu}\Psi) \\ &\quad + \frac{1}{8}(\bar{\chi}\eta^{\mu\nu}\chi)(\bar{\Psi}\eta_{\mu\nu}\gamma_5\Psi). \end{split} \tag{B5}$$
