# <span id="page-0-1"></span>MultiverSeg: Scalable Interactive Segmentation of Biomedical Imaging Datasets with In-Context Guidance

<span id="page-0-0"></span>Figure 1. MultiverSeg enables users to rapidly segment new datasets. The MultiverSeg network takes as input an image to segment and user interactions, along with a context set of previously segmented image-segmentation pairs (left). As the user completes more segmentations, those images and segmentations become additional inputs to the model, populating the context set. As the context set of labeled images grows, the number of interactions required to achieve an accurate segmentation decreases (right).

# Abstract

*Medical researchers and clinicians often need to perform novel segmentation tasks on a set of related images. Existing methods for segmenting a new dataset are either interactive, requiring substantial human effort for each image, or require an existing set of manually labeled images.*

*We introduce a system, MultiverSeg, that enables practitioners to rapidly segment an entire new dataset without requiring access to any existing labeled data from that task or domain. Along with the image to segment, the model takes user interactions such as clicks, bounding boxes or scribbles as input, and predicts a segmentation. As the user segments more images, those images and segmentations become additional inputs to the model, providing context. As the context set of labeled images grows, the number of interactions required to segment each new image decreases.*

*We demonstrate that MultiverSeg enables users to interactively segment new datasets efficiently, by amortizing the number of interactions per image to achieve an accurate segmentation. Compared to using a state-ofthe-art interactive segmentation method, using MultiverSeg* *reduced the total number of scribble steps by 53% and clicks by 36% to achieve 90% Dice on sets of images from unseen tasks. We release code and model weights at [https://multiverseg.csail.mit.edu.](https://multiverseg.csail.mit.edu)*

# 1. Introduction

Segmentation is an important step in biomedical image analysis pipelines for both biomedical research and clinical care. Biomedical researchers and clinical researchers often acquire novel images types or identify new regions of interest, and need to perform new segmentation tasks. Typically, scientists want to segment the same region of interest in many similar images from a new dataset.

Manually segmenting images is labor-intensive and requires domain expertise. *Interactive* segmentation systems, in which a user provides a few clicks or scribbles on an image to produce a predicted segmentation, help to speed up the annotation of individual images. But with existing interactive segmentation systems, the user must independently repeat the same process for each image [\[59,](#page-10-0) [82,](#page-11-0) [85,](#page-11-1) [126,](#page-13-0) [133\]](#page-13-1). It would be impactful if the segmentation system became more accurate as the user completed more segmenta<span id="page-1-0"></span>tions from the same task, learning from experience.

We propose MultiverSeg, a new interactive system that progressively reduces the number of user interactions needed to predict accurate segmentations, as more images are segmented in a particular task (Fig. [1\)](#page-0-0). MultiverSeg takes as input user interactions for a new image, along with a *context set*, of example (previously segmented) imagesegmentation pairs. To segment a new dataset, the user begins by interactively segmenting the first image. Once completed, the example becomes an input to MultiverSeg, providing context for the segmentation of subsequent examples. The user interactively segments the next image with MultiverSeg using bounding boxes, clicks or scribbles. As the user labels more images, the context set grows and the number of interactions required to achieve the desired segmentation of the subsequent image decreases, often to zero. Unlike existing interactive segmentations systems [\[59,](#page-10-0) [76,](#page-11-2) [77,](#page-11-3) [82,](#page-11-0) [85,](#page-11-1) [107,](#page-12-0) [122,](#page-13-2) [123,](#page-13-3) [126,](#page-13-0) [131,](#page-13-4) [136\]](#page-14-0) where the work required to segment a dataset is linear in the number of images, MultiverSeg enables users to rapidly segment entire datasets.

This paper

- Presents MultiverSeg, a new interactive segmentation framework that progressively reduces the amount of user interaction needed to predict accurate segmentations, as more images are segmented in a particular task.
- Introduces a model that segments an image given user prompts (bounding boxes, clicks and/or scribbles) and a variably-sized context set of previously labeled example images and segmentations. This network enables scalable segmentation of datasets by performing *interactive* segmentation *in context*.
- Demonstrates that MultiverSeg can dramatically reduce the total number of user interactions needed to segment a collection of medical images.

# 2. Related Work

Interactive Segmentation. Recent interactive segmentation models can generalize to new segmentation tasks in medical [\[126\]](#page-13-0) and natural images [\[59,](#page-10-0) [103\]](#page-12-1). While these methods are effective for segmenting single images, they require prohibitively extensive human interaction when segmenting large datasets. To incorporate new information, they must be retrained or fine-tuned. In contrast, at inference time MultiverSeg can be conditioned on example segmentations from the new task, dramatically reducing the human effort required for accurate segmentation.

In-Context Learning. Recent *in-context learning* approaches to segmentation [\[16,](#page-8-0) [20,](#page-9-0) [45,](#page-10-1) [101,](#page-12-2) [124,](#page-13-5) [128\]](#page-13-6) enable users to perform new tasks by providing a set of labeled examples to the model at inference time. These methods often need existing large context sets to achieve adequate performance, and provide no mechanism for correcting predicted segmentations.

A few works have explored in-context segmentation using a context set of example images with user annotations on those example images. OnePrompt [\[128\]](#page-13-6) segments a medical image given exactly one context example with click, scribble, bounding box or mask annotation. In contrast, MultiverSeg has mechanisms to facilitate a variable number of context set entries and enables users to incorporate interactions on the target image even when given the context of previous segmentations, enabling substantially richer use cases. LabelAnything [\[23\]](#page-9-1) is a few-shot framework that enables multi-label segmentation of a target natural image with a small variable size context set of example images with click, box, or mask annotations. In contrast, MultiverSeg can leverage *large* context sets, and enables users to provide interactions on the target image and make corrections to refine the prediction to get the desired segmentation.

Continual Learning. One approach to segmenting a new dataset involves manually labeling a large number of images, and then training an automatic taskspecific model [\[51\]](#page-10-2) to segment the rest. For example, MonaiLabel [\[26\]](#page-9-2) is an open-source tool that packages this process. In contrast, MultiverSeg can be adapted *at inference time* using new labels (collected manually or interactively) without the need to re-train.

Many works have sought to improve task-specific interactive segmentation performance by fine-tuning foundation models, either through full fine-tuning [\[56\]](#page-10-3) or more efficient adaption techniques [\[46,](#page-10-4) [73,](#page-11-4) [95,](#page-12-3) [102,](#page-12-4) [120,](#page-13-7) [129,](#page-13-8) [134\]](#page-14-1). The fine-tuning must be repeated for each new task or group of tasks. It requires many relevant annotated images and the substantial computational resources needed to train a large model.

Annotation-Efficient Learning. Another approach to segmenting a new dataset is to collect sparse annotations on many images and train an automatic segmentation model using these annotations for supervision. The annotations may be bounding boxes [\[65,](#page-10-5) [117\]](#page-13-9), clicks [\[75,](#page-11-5) [78,](#page-11-6) [106\]](#page-12-5) or scribbles [\[35,](#page-9-3) [70,](#page-11-7) [71,](#page-11-8) [83,](#page-11-9) [135\]](#page-14-2). These methods require the manual annotation of many training images and retraining for each new task. Other methods use annotations to perform online learning, using user corrections as a source of supervision to update the model weights at test time [\[4,](#page-8-1) [5,](#page-8-2) [60,](#page-10-6) [113,](#page-13-10) [121,](#page-13-11) [140\]](#page-14-3). In contrast, MultiverSeg is trained only once on a large corpus of datasets once, and then can be used to segment new datasets at inference time without any retraining, using graphical interactions and previous segmentations as *input*.

<span id="page-2-1"></span><span id="page-2-0"></span>

Figure 2. MultiverSeg Architecture. The MultiverSeg network (left) takes as input a stack of target image inputs  $q_i$  and a context set of image-segmentation pairs  $\{(x_l, y_l)\}_{l=1}^m$ . The target image inputs include a target image  $x_i$ , optional user interactions  $u_{i,j}$ , and a previous predicted segmentation  $\hat{y}_{i,j-1}$  if available. The architecture is comprised of an encoder-decoder structure similar to a UNet [\[105\]](#page-12-6). We use a CrossBlock [\[16\]](#page-8-0) (right) with additional normalization layers [\[6\]](#page-8-3) to interact the features of the target image inputs  $q_i$  with the features of the context set inputs  $V = \{v_l\}_{l=1}^m$  throughout the network.

# 3. Methods

#### 3.1. Problem Setup

For a new task t, we aim to segment a set of images  $\{x_i^t\}_{i=1}^N$ into their corresponding segmentations  $\{y_i^t\}_{i=1}^N$ .

We assume a user provides manual interactions for one image at a time, to indicate the desired segmentation. These interactions may be iterative even for a single image, sometimes indicating corrections based on a previous prediction  $\hat{y}_{i,j-1}^t$ . We let  $u_{i,j}^t$  be the interactions provided for image  $x_i$ at step j, and  $\hat{y}_{i,k_i}^{t}$  be the final predicted segmentation for image  $x_i$  after  $k_i$  steps of interaction.

We want to maximize the quality of predicted segmentations  $\{\hat{y}_{i,k_i}^t\}_{i=1}^N$  for an entire dataset,

$$
\min \sum_{i=1}^{N} \mathcal{L}_{seg}(y_i^t, \hat{y}_{i,k_i}^t)
$$
\n(1)

while minimizing the *total* number of user interactions

$$
\sum_{i=1}^{N} \sum_{j=1}^{k_i} u_{i,j}^t,
$$
\n(2)

where  $\mathcal{L}_{seg}$  is a segmentation distance metric,  $\{y_i^t\}_{i=1}^N$  are the ground truth segmentation maps, and  $k_i$  is the number of steps of interaction for image  $i$ .

# 3.2. MultiverSeg

We introduce a framework that enables rapid progressive segmentation of an entire dataset. The key component is a method that segments image  $x_i^t$  based on user interactions  $u_{i,j}$  and a set of image-segmentation maps  $S_i^t$  =  $\{(x_i^t, \hat{y}_{i,k_l}^t)\}_{l=1}^{i-1}$  for previous segmented images.

**First image.** When segmenting the first image  $x_0^t$  of a new task t, the context set  $S_0^t$  is empty. We build on learningbased interactive segmentation approaches [\[59,](#page-10-0) [126\]](#page-13-0), to learn a function  $g_{\phi}(x_i^t; u_i, \hat{y}_{i,j-1}^t)$  that at step j produces a segmentation  $\hat{y}_{i,j}$  of image  $\hat{x}^t$ , given a set of user interactions  $u_{i,j}$  and a previously predicted segmentation  $\hat{y}_{i,j-1}^t$ . The interactions  $u_i$ , which may include positive or negative scribbles, positive or negative clicks, and bounding boxes, are provided by a user who has access to the image  $x<sup>t</sup>$  and previous prediction  $\hat{y}_{i-1}^t$ . For  $g_{\phi}(\cdot)$ , we use the pre-trained ScribblePrompt-UNet [\[126\]](#page-13-0).

**Subsequent images.** For subsequent images  $x_{i>0}^t$ , the context set  $S_i^t = \{(x_i^t, \hat{y}_{i,k_l}^t)\}_{l=0}^{i-1}$  encompass the previously segmented images and the resulting segmentation maps. We learn a function  $f_{\theta}(x^t; u_i, \hat{y}_{i-1}^t; S^t)$  with parameters  $\theta$  that leverages the set of user interactions  $u_i$ , previous prediction  $\hat{y}_{i-1}^t$ , and context set  $S_i^t$  to produce a segmentation  $\hat{y}_i$ . As more images are segmented, the context set  $S_i^t$  grows, leading to fewer interactions  $u_i$  necessary for accurate segmentation of each subsequent image.

## 3.2.1. Architecture

We employ a convolutional architecture (Fig. [2\)](#page-2-0) for  $f_{\theta}$  with an encoder-decoder structure, building on recent in-context learning strategies [\[16\]](#page-8-0). The architecture uses a *CrossBlock* mechanism to mix information between the context set, which can be of variable size, and the inputs corresponding to the user interactions, which pertain to the target image.

Target image inputs. The target image inputs consist of the target image  $x_i$  and graphical user interactions  $u_{i,j}$ , and a previous prediction  $\hat{y}_{i,j-1}$  if available. The interactions may include bounding boxes, positive clicks and scribbles, and negative clicks and scribbles, represented as three intensity-based masks [\[126\]](#page-13-0). We stack the target inputs <span id="page-3-2"></span>leading to five channels, where the first channel contains the input image, and the other channels contain the optional interactions and an optional previous prediction. When there are no interactions or there is no previous prediction, these channels are set to zero.

**Context set inputs.** For each of the  $N$  examples in the context set, we stack the image and segmentation.

CrossBlock. We use a modified CrossBlock mechanism to interact intermediate target features  $q$  with intermediate features of the context set inputs  $v$  [\[16\]](#page-8-0).

We first use a *cross-convolution* layer to interact a target feature map q with a set of context feature maps  $V =$  ${v_i}_{i=1}^n$ :

CrossConv
$$
(q, V; \theta_z) = \{z_i\}_{i=1}^n
$$
,  
for  $z_i = \text{Conv}(q||v_i; \theta_z)$ . (3)

This layer is used within the Crossblock to produce features of target representation q and context set  $V$  at each step in the network:

CrossBlock
$$
(q, V; \theta_{z,q,v}) = (q', V')
$$
, where:  
\n $z_i = \text{LN}(A(\text{CrossConv}(q, v_i; \theta_z)))$  for  $i = 1, 2, ..., n$   
\n $q' = \text{LN}(A(\text{Conv}(1/n \sum_{i=1}^n z_i; \theta_q)))$   
\n $v'_i = \text{LN}(A(\text{Conv}(z_i; \theta_v)))$  for  $i = 1, 2, ..., n$ ,

where  $A(x)$  is a non-linear activation function and  $LN(\cdot)$ is LayerNorm [\[6\]](#page-8-3).

Network. We employ a UNet-like encoder-decoder architecture, where each convolutional block is replaced by a CrossBlock, enabling the target-related inputs to interact with the previously segmented images at every image scale [\[16,](#page-8-0) [105\]](#page-12-6).

#### 3.3. Training

We summarize the training process in Algorithm [1.](#page-3-0) During training, we first sample a random task  $t$ , and then sample a training example  $(x_i^t, y_i^t)$  and context set  $S_i^t$  =  $\{(x_i^t, y_i^t)\}_{i=0}^n$  of random size  $n \in [0, N]$ . We use ground truth segmentation labels in the context set.

We minimize the difference between the true segmentation  $y^t$  and each of the k iterative predictions  $\hat{y}_{i,0}, \ldots, \hat{y}_{i,k}$ given a context set  $S^t$ ,

<span id="page-3-1"></span>
$$
\mathcal{L}(\theta; \mathcal{T}) = \mathbb{E}_{t \in \mathcal{T}} \left[ \mathbb{E}_{(x_i^t, y_i^t; S^t) \in t} \left[ \sum_{j=1}^k \mathcal{L}_{seg} \left( y_i^t, \hat{y}_{i,j}^t \right) \right] \right], \quad (5)
$$

where  $\hat{y}_{i,j}^t = f_{\theta}(x_i^t, u_{i,j}^t, \hat{y}_{i,j-1}^t; S_i^t)$ ,  $\mathcal{L}_{seg}$  is a supervised segmentation loss,  $x_t \notin S^t$  and  $\hat{y}_0^t = \mathbf{0}$ .

Prompt Simulation. We simulate random combinations of scribbles, clicks and bounding boxes during training following prompt simulations procedures described in [\[126\]](#page-13-0). We

<span id="page-3-0"></span>Algorithm 1 MultiverSeg Training Loop using SGD with learning rate  $\eta$  over tasks  $\mathcal T$  with independently sampled context set, main architecture  $f_{\theta}$ , in-task augmentations  ${\rm Aug}_t$  and task augmentations  ${\rm Aug}_T$ 

<span id="page-3-3"></span>simulate  $k$  steps of interactive segmentation for each example during training. For the first step  $(i = 1)$ , we sample the combination of interactions (bounding box, clicks, scribbles) and the number of initial positive and negative interactions  $n_{pos}, n_{neg} \sim U[n_{min}, n_{max}]$ . The initial interactions  $u_1$  are simulated using the ground truth label  $y^t$ . In subsequent steps, we sample correction scribbles or clicks from the error region  $\varepsilon_{i-1}^t$  between the last prediction  $\hat{y}_{i-1}^t$ and the ground truth  $y<sup>t</sup>$ . Since a user can make multiple corrections in each step, we sample  $n_{cor} \sim U[n_{min}, n_{max}]$ corrections (scribbles or clicks) per step.

# 4. Data

Task Diversity. We use a collection of 78 biomedical imaging datasets (Appendix [B\)](#page-15-0) and synthetically generated images and tasks [\[16,](#page-8-0) [101,](#page-12-2) [126\]](#page-13-0). The collection includes a diverse array of biomedical domains, such as eyes [\[44,](#page-10-7) [69,](#page-11-10) [86,](#page-11-11) [99,](#page-12-7) [116\]](#page-13-12), thorax [\[100,](#page-12-8) [108,](#page-12-9) [109,](#page-12-10) [111,](#page-13-13) [112\]](#page-13-14), spine [\[80,](#page-11-12) [109,](#page-12-10) [141\]](#page-14-4), cells [\[17,](#page-8-4) [18,](#page-8-5) [30,](#page-9-4) [32,](#page-9-5) [38,](#page-9-6) [79,](#page-11-13) [142\]](#page-14-5), skin [\[19\]](#page-8-6), abdominal [\[12,](#page-8-7) [14,](#page-8-8) [41,](#page-9-7) [52,](#page-10-8) [55,](#page-10-9) [64,](#page-10-10) [66,](#page-11-14) [68,](#page-11-15) [74,](#page-11-16) [81,](#page-11-17) [87,](#page-11-18) [100,](#page-12-8) [104,](#page-12-11) [112,](#page-13-14) [115\]](#page-13-15), neck [\[61,](#page-10-11) [94,](#page-12-12) [97,](#page-12-13) [98\]](#page-12-14), brain [\[2,](#page-8-9) [7,](#page-8-10) [33,](#page-9-8) [42,](#page-9-9) [62,](#page-10-12) [63,](#page-10-13) [88,](#page-11-19) [89,](#page-12-15) [91,](#page-12-16) [112\]](#page-13-14), bones [\[40,](#page-9-10) [109,](#page-12-10) [118\]](#page-13-16), teeth [\[1,](#page-8-11) [50\]](#page-10-14) and lesions [\[3,](#page-8-12) [112,](#page-13-14) [137,](#page-14-6) [139\]](#page-14-7).

Task Definition. We define a 2D segmentation task as a combination of dataset, modality, axis (for 3D modalities), and binary label. For datasets with multiple segmentation labels, we consider each label separately as a binary segmentation task and for 3D modalities we use the slice with maximum label area and the middle slice from each volume.

<span id="page-4-0"></span>Data Augmentation. We perform both task augmentation and within-task data augmentation to increase the diversity of segmentation tasks [\[16\]](#page-8-0). For task augmentation, the same augmentation is applied to the target example and the entries of the context set to change the segmentation task. For within-task augmentation, we apply data augmentation where the parameters are randomly sampled for each target example and context set entry, to vary the examples within a task. Augmentations are applied prior to simulating the user interactions. We detail the augmentations in Appendix [B.3.](#page-16-0)

Synthetic Data. Synthetic data can help improve generalization [\[13,](#page-8-13) [16,](#page-8-0) [34,](#page-9-11) [126\]](#page-13-0). We use some fully synthetic data (images and labels) similar to strategies used for in-context learning [\[16\]](#page-8-0).

Synthetic Tasks. We introduce a new approach for constructing synthetic tasks from real images. Given a single image  $x_0$  we construct a set of images  $\{x'_i, y'_i\}_{i=1}^{m+1}$  representing a synthetic task. We then partition this set into a target example and context set of size  $m$  for training.

Given an image  $x_0$ , we first generate a synthetic label  $y_{synth}$  by applying a superpixel algorithm [\[28\]](#page-9-12) with scale parameter  $\lambda \sim U[1, \lambda_{max}]$  to partition the image into a multi-label mask of k superpixels  $z \in \{1, \ldots, k\}^{n \times n}$ . We then randomly select a superpixel  $y_{synth} = 1(z = c)$  as a synthetic label.

To generate a set of  $m + 1$  images representing the same task, we duplicate  $(x_0, y_{synth})$ ,  $m + 1$  times and apply aggressive augmentations to vary the images and segmentation labels [\[16,](#page-8-0) [138\]](#page-14-8). We detail these augmentations and provide examples in Appendix [B.2.](#page-15-1)

During training, we replace a randomly sampled target example  $(x_0^t, y_0^t)$  and context set  $S^t$  with synthetic ones with probability  $p_{synth}$ . We use  $p_{synth} = 0.5$ .

# 5. Experimental Setup

We evaluate MultiverSeg and baselines in segmenting a set of images, representing a segmentation task unseen during training. We simulate the process of interactively segmenting each image in a dataset, and adding segmentations to the context set as they are completed.

#### 5.1. Training MultiverSeg

To learn  $f_{\theta}(\cdot)$ , we minimize eq. [\(5\)](#page-3-1) where  $\mathcal{L}_{seq}$  is the sum of soft Dice Loss [\[27\]](#page-9-13) and Focal Loss [\[72\]](#page-11-20) with  $\gamma = 20$  [\[59\]](#page-10-0). We minimize the loss using the Adam optimizer [\[57\]](#page-10-15). We simulate 3 steps of interactive segmentation for each example during training. We simulate 1-3 positive and 0-3 negative interactions in the first step, and 1-3 corrections per subsequent step. We randomly sample a context set of size  $m \sim U[0, 64]$  for each sample, and train with a batch size of 2 and learning rate of  $\eta = 10^{-4}$ .

#### 5.2. Data

We partition our collection of 78 datasets into 67 datasets for training and 11 datasets for evaluation. We report results on 11 held-out datasets that were unseen by the model during training. These datasets cover 83 tasks and 8 modalities, including unseen image types, anatomies, and labels. The evaluation datasets cover a variety of modalities (MRI, CT, ultrasound, fundus photography, microscopy) and anatomical regions of interest (brain, teeth, bones, abdominal organs, muscles, heart, thorax, cells), including both healthy anatomy and lesions [\[2,](#page-8-9) [3,](#page-8-12) [11,](#page-8-14) [40,](#page-9-10) [44,](#page-10-7) [66,](#page-11-14) [66,](#page-11-14) [100,](#page-12-8) [118,](#page-13-16) [141,](#page-14-4) [142\]](#page-14-5).

### 5.3. Prompt Simulation

Throughout our experiments, we consider two inferencetime interaction protocols:

- Center Clicks: One positive click in the center of the largest component to start (step 1), followed by one (positive or negative) correction click per step in the center of the largest component of the error region.
- Centerline Scribbles: One positive and one negative centerline scribble to start (step 1), followed by one correction centerline scribble per step.

We selected these protocols because center clicks are commonly used for evaluation [\[10,](#page-8-15) [47,](#page-10-16) [59,](#page-10-0) [76,](#page-11-2) [77,](#page-11-3) [114,](#page-13-17) [130\]](#page-13-18) and centerline scribbles were the most effective scribble type in previous work [\[126\]](#page-13-0). We simulate the interactions following ScribblePrompt [\[126\]](#page-13-0).

## 5.4. Baselines

Interactive Segmentation Baselines. We compare to ScribblePrompt [\[126\]](#page-13-0) a state-of-the-art interactive segmentation method for medical imaging that uses bounding boxes, clicks and scribbles. ScribblePrompt produces more accurate segmentations on unseen biomedical imaging datasets and works with more types of interactions compared to SAM [\[59\]](#page-10-0) and medical imaging variants [\[85,](#page-11-1) [132\]](#page-13-19).

In-Context Segmentation Baselines. We compare to UniverSeg [\[16\]](#page-8-0), a general state-of-the-art in-context segmentation model that was developed and evaluated on a diverse collection of biomedical images.

Interactive Segmentation in Context Baselines. We construct a new baseline, *SP+UVS*, by combining UniverSeg [\[16\]](#page-8-0) and ScribblePrompt [\[126\]](#page-13-0). We use the publicly available pre-trained weights for each model. When the context set is empty, we use ScribblePrompt. When provided with a context set, we first make a prediction using UniverSeg, and then refine the prediction with ScribblePrompt.

Consistent with the original published results, we find that UniverSeg has poor performance for small context sets

<span id="page-5-2"></span><span id="page-5-0"></span>

Figure 3. Interactions to target Dice on unseen tasks. Number of interactions needed to reach a 90% Dice as a function of the example number being segmented. For the  $n^{th}$  image being segmented, the context set has  $n$  examples. MultiverSeg requires substantially fewer number of interactions to achieve 90% Dice than the baselines, and as more images are segmented, the average number of interactions required decreases dramatically. Shaded regions show 95% CI from bootstrapping.

and initializing ScribblePrompt using the UniverSeg prediction hurts performance when the context set is small (Fig. [14\)](#page-24-0). Thus, for context sets with fewer than 5 examples, we ignore the context and only use ScribblePrompt to make predictions.

We did not compare to OnePrompt [\[128\]](#page-13-6) and LabelAnything [\[23\]](#page-9-1) because the pre-trained weights were not publicly available and reproducing the training datasets and training pipelines is beyond the scope of this work. Additionally, these models are not designed to perform interactive segmentation in context. We provide more discussion in Appendix [C.1.](#page-16-1)

Supervised Benchmarks (upper bound). We also train task-specific models using the popular nnUNet pipeline [\[51\]](#page-10-2), which automatically configures the model architecture and training based on the data properties. We train a separate nnUNet model for each held-out 2D task, and report results from the collection of models. These models act as upper bounds on segmentation accuracy, because they are fully-supervised and have access to ground truth training data not available to the other algorithms.

## 5.5. Metrics

We primarily evaluate segmentation quality using Dice score [\[27\]](#page-9-13), and show 95th percentile Hausdorff distance [\[49\]](#page-10-17) in Appendix [D.2.](#page-19-0)

## 6. Experiment 1: Evaluation

In this experiment, we evaluate different approaches to segmenting an entire new biomedical dataset. We compare MultiverSeg to ScribblePrompt, which performs interactive segmentation of each image independently, and

<span id="page-5-1"></span>

Figure 4. Change in total interactions per task. We show average change per task in total number of clicks and scribble steps to segment 18 images to  $\geq 90\%$  Dice, comparing MultiverSeg to each baseline method. In all scenarios, MultiverSeg required fewer interactions than both baselines. Error bars show 95% CI from bootstrapping.

to SP+UVS, which combines ScribblePrompt with an incontext segmentation model (UniverSeg). We show that MultiverSeg outperforms both techniques.

# 6.1. Setup

We evaluate the number of interactions required to achieve a target Dice score on each image using different methods, or a maximum number of interactions if the score was not reached. We use 90% as a target Dice score, because our collection of fully-supervised task-specific nnUNet models achieves an average Dice of  $90.15 \pm 0.54$  on the same test data. We set 20 center clicks or 10 steps of centerline scribbles as the maximum number of interactions.

For each method and task, we begin by interactively segmenting one randomly sampled image from the training split to  $\geq 90\%$  Dice using ScribblePrompt [\[126\]](#page-13-0). This example is used to seed the context set. We then randomly sample (without replacement) 18 images from the test split, and simulate sequentially segmenting each image.

Data. We report results averaged across 200 simulations for each held-out segmentation task. We exclude tasks with fewer than 18 test examples, leaving 161 tasks from 8 evaluation datasets [\[1–](#page-8-11)[3,](#page-8-12) [11,](#page-8-14) [40,](#page-9-10) [118,](#page-13-16) [125,](#page-13-20) [142\]](#page-14-5). We further discuss the choice of this cutoff in Appendix [D.1.](#page-19-1)

### 6.2. Results

Interactions per image as a function of dataset size. As more examples are segmented and the context set grows, the number of interactions required to get to 90% Dice (NoI90)

<span id="page-6-1"></span><span id="page-6-0"></span>

Figure 5. **Example predictions after 1 interaction step**. We show predictions for MultiverSeg and baselines for a random example with a context of 10 examples that were previously segmented to  $\geq$ 90% Dice from each held-out task. For each method, we show the prediction after 1 step of interaction: 1 step of centerline scribbles for ACDC [\[11\]](#page-8-14), BUID [\[3\]](#page-8-12), and PanDental [\[1\]](#page-8-11), and 1 center click for SCR [\[118\]](#page-13-16), WBC [\[142\]](#page-14-5) and HipXRay [\[40\]](#page-9-10).

on the n<sup>th</sup> example using MultiverSeg decreases substantially (Fig. [3\)](#page-5-0). For ScribblePrompt, NoI90 is approximately constant, because it is not designed to learn from previous examples. With SP+UVS, the number of interactions decreases as more examples are segmented, but it requires more interactions than MultiverSeg. Results by task in Appendix [D.2](#page-19-0) illustrate a similar trend. Fig. [5](#page-6-0) shows predictions for the  $10^{th}$  example after 1 step of interaction.

Total interactions. On average, using MultiverSeg reduced the number of scribble steps required to segment each dataset by  $(52.70 \pm 3.60)\%$  and the number of clicks required by  $(35.61 \pm 1.95)\%$  (Fig. [4\)](#page-5-1). For larger sets of images, using MultiverSeg results in even greater reductions in the total number of user interactions (Appendix [D.2\)](#page-19-0).

Context Set Quality. MultiverSeg was trained with ground truth context set labels. However, at inference time, the context set only includes previously predicted segmentations.

For both MultiverSeg and SP+UVS, thresholding the predictions at 0.5 before adding them to the context set improved the accuracy of predictions for subsequent images. We show results in Appendix [D.2](#page-19-0) with and without this modification.

As an upper bound on performance, we also evaluated using ground truth labels in the context set instead of predicted segmentations (Appendix [D.2\)](#page-19-0). Using ground truth context labels decreases the number of interactions to achieve 90% Dice for both MultiverSeg and SP+UVS, but MultiverSeg still requires fewer interactions.

Bootstrapping In-Context Segmentation. Another approach to segmenting a new dataset is to manually segment an image and then use an in-context segmentation model to segment the rest of the images. We experimented with bootstrapping UniverSeg: starting from a single labeled example as the context set, we sequentially segment each image with UniverSeg and then add it to the context set for the next example. This approach did not produce accurate results  $(51.02 \pm 0.07$  Dice), likely because UniverSeg has poor performance for small context sets (Fig. [6\)](#page-7-0) and/or con-

<span id="page-7-2"></span><span id="page-7-0"></span>

Figure 6. In-context segmentation performance across context set sizes. We compare MultiverSeg to an in-context segmentation method [\[16\]](#page-8-0) given ground truth context labels. Shading shows 95% CI from bootstrapping.

text sets with imperfect labels. Because UniverSeg does not have a mechanism to incorporate corrections, it was not possible to achieve 90% Dice for most images. We show results experimenting with this approach in Appendix [D.2.2.](#page-20-0)

# 7. Experiment 2: Analysis

When segmenting images sequentially, as in the previous experiment, the performance on the  $n^{th}$  image is correlated with the predictions on the previous images. However, in some realistic instances, a few ground truth segmentations might already be available from other previous segmentation efforts. In the following experiments, we analyze MultiverSeg using randomly sampled context sets with *ground truth* labels. We report results on the test split of 11 evaluation datasets not used during training.

## 7.1. In-Context Segmentation

Setup. We compare the predictions of MultiverSeg to a generalizable in-context learning baseline, UniverSeg [\[16\]](#page-8-0), given different context set sizes. For each test example, we make 10 predictions with context sets randomly sampled with replacement from the training split of the same dataset.

Results. MultiverSeg produces higher Dice score segmentations than UniverSeg across all context set sizes (Fig. [6\)](#page-7-0). In the previous experiment, MultiverSeg required fewer interactions than SP+UVS, in part because its initial incontext predictions were more accurate than those of UniverSeg. This is likely due to MultiverSeg being trained on a larger collection of data (67 vs. 53 datasets) with more features per CrossBlock (256 vs. 64) and normalization layers.

## 7.2. Interactive Segmentation in Context

Setup. We evaluate the interactive segmentation performance of MultiverSeg given context sets of different sizes. Using MultiverSeg, we first make a prediction based only on the context set (without interactions). We then simulate corrections using either center clicks or centerline scribbles,

<span id="page-7-1"></span>

Figure 7. Interactive segmentation in context. MultiverSeg's interactive segmentation performance improves as the context set size grows. We first make an initial prediction based on the context set (step 0), and then simulate corrections (clicks or scribbles). Shading shows 95% CI from bootstrapping.

and make additional predictions. For each example, we simulate interactive segmentation with 10 different random seeds and randomly sampled context sets of ground truth segmentation maps.

Results. Interactive segmentation performance improves as the size of the context set increases, demonstrating MultiverSeg is able to use information from the context set to improve its predictions (Fig. [7\)](#page-7-1). There are diminishing returns to increasing the context set size. For example, performing another step of scribbles typically leads to a larger increase in Dice score, compared to doubling the context set size.

# 8. Conclusion

We presented MultiverSeg, an interactive framework that enables rapid segmentation of an entire dataset of images, even for new tasks. MultiverSeg leads to a substantial reduction of user interactions as more images are segmented.

To enable MultiverSeg, we introduce the first model that can perform *interactive* segmentation of biomedical images *in context*. The network segments an image given user interactions and a context set of previously labeled examples. Compared to ScribblePrompt, a state-of-the-art interactive segmentation model, MultiverSeg reduces the number of interactions required to accurately segment a set of images, by as much as 50% on the first 18 images of a dataset.

MultiverSeg opens up new opportunities for research into how best to prioritize sequentially segmenting images from a new dataset. Future research works could improve upon MultiverSeg by investigating better context selection techniques [\[31,](#page-9-14) [48,](#page-10-18) [127\]](#page-13-21) to prioritize labeling images whose labels would be most informative for the segmentation task at hand.

MultiverSeg has the potential to dramatically reduce the manual burden involved in segmenting datasets of biomedical images.

# <span id="page-15-2"></span>MultiverSeg: Scalable Interactive Segmentation of Biomedical Imaging Datasets with In-Context Guidance

Supplementary Material

# A. MultiverSeg Method

### A.1. Architecture

CrossConv. We implement the CrossConvolutional layer slightly differently from [\[16\]](#page-8-0). To avoid duplicate convolutions on the context features  $v_i$  in Eq. [\(4\)](#page-3-3), we partition weights  $\theta_z$  channel-wise into  $\{\theta_{z_1}, \theta_{z_2}\}\$  and implement  $z_i = LN(A(\text{Conv}(q, \theta_{z_1}) + \text{Conv}(v_i, \theta_{z_2})))$  where q is the target feature map and  $v_i$  is the feature map corresponding to context set entry  $i$ . We zero out the bias terms in Conv $(\cdot, \theta_{z_2})$  such that the computation is equivalent to  $z_i = LN(A(\text{Conv}(q||v_i; \theta_z))).$ 

**Network.** We implement  $f_{\theta}(\cdot)$  using an encoder with 5 encoder CrossBlock stages and a decoder with 4 CrossBlock stages. Each stage has 256 output features and LeakyReLU non-linearities after each convolution. We use bilinear interpolation for upsampling and downsampling.

The CrossBlock mechanism requires at least one context set entry. If the context set is empty, we use a dummy context set entry consisting of an image and segmentation with uniform value of 0.5.

## <span id="page-15-0"></span>B. Data

#### B.1. Datasets

We build on large dataset gathering efforts like MegaMedical [\[16,](#page-8-0) [101,](#page-12-2) [126\]](#page-13-0) to compile a collection of 78 open-access biomedical imaging datasets for training and evaluation, covering over 54k scans, 16 image types, and 713 labels.

Division of Datasets. The division of datasets and subjects for training, model selection, and evaluation is summarized in Tab. [1.](#page-16-3) The 78 datasets were divided into 67 training datasets (Tab. [3](#page-17-1) and 11 evaluation datasets (Tab. [2\)](#page-16-4). Data from 9 (out of 11) of the evaluation datasets were used for model selection and final evaluation. The other 2 evaluation datasets were completely held-out from model selection and only used in the final evaluation.

Division of Subjects. We split each dataset into 60% train, 20% validation, and 20% test by subject. We used the "train" splits from the 67 training datasets to train MultiverSeg models. We use the "validation" splits from the 67 training datasets and 9 validation datasets to select the best model checkpoint. We report final evaluation results across 11 held-out "test" splits of the 11 evaluation datasets to maximize the diversity of tasks and modalities in our evaluation set (Tab. [2\)](#page-16-4). No data from the 9 validation datasets or 2 test datasets were seen by MultiverSeg during training.

Task Definition. We define a 2D segmentation task as a combination of (sub)dataset, axis (for 3D modalities), and label. For datasets with multiple segmentation labels, we consider each label separately as a binary segmentation task. For datasets with sub-datasets (e.g., malignant vs. benign lesions) we consider each cohort as a separate task. For multi-annotator datasets, we treat each annotator as a separate label. For instance segmentation datasets, we considered all instances as a single label.

3D Datasets. For 3D modalities, we use the slice with maximum label area ("maxslice") and the middle slice ("midslice") for each volume for training of MultiverSeg. For the 3D evaluation datasets (BTCV Cervix [\[66\]](#page-11-14), ACDC [\[11\]](#page-8-14), SCD [\[100\]](#page-12-8), SpineWeb [\[141\]](#page-14-4), COBRE [\[2\]](#page-8-9)) we evaluated the slice with the maximum label area for each subject, as in [\[126\]](#page-13-0). We also considered evaluating on the middle slice, as in [\[16,](#page-8-0) [101,](#page-12-2) [128\]](#page-13-6) and saw similar trends on the validation data. However, we opted for evaluation on maxslices because for our 3D test dataset (COBRE) some labels do not appear in the midslices. Due to the large number of tasks in COBRE, we only consider coronal slices from COBRE for evaluation.

Data Processing. We rescale image intensities to [0,1] and resize images to 128x128.

Data Sampling. During training, we sample image, segmentation pairs hierarchically – by dataset and modality, axis, and then label – to balance training on datasets of different sizes.

### <span id="page-15-1"></span>B.2. Synthetic Task Generation

We introduce a new approach for constructing synthetic tasks from real images. Given a single image  $x_0$ , we construct a set of images  $\{x'_i, y'_i\}_{i=1}^{m+1}$  representing a synthetic task. We then partition this set into a target example and context set of size m for training.

Related Work. Although previous work found that training on a mix of real and synthetic segmentation *labels* based on image superpixels is useful for improving generalization in interactive segmentation  $[126]$ , we do not use such data here. That approach cannot be directly applied to MultiverSeg because it does not produce semantically consistent labels across multiple images.

Method. To build a synthetic task from an image, we first generate a synthetic label and then perform aggressive aug<span id="page-16-3"></span><span id="page-16-2"></span>Table 1. Dataset split overview. Each dataset was split into 60% train, 20% validation and 20% test by subject. Data from the "train" splits of the 67 training datasets were used to train the models. The MultiverSeg models did not see any data from the validation datasets or test datasets during training. Data from the "validation" split of the 9 validation datasets was used for MultiverSeg ( MVS ) model selection and experimenting with different evaluation methods of baselines. We report final results on the held-out test splits of 11 evaluation datasets: data from the "test" splits of the 9 validation datasets and the "test" splits of the 2 test datasets. To train the fully-supervised nnUNet baselines, we used the training and validation splits of the 11 evaluation datasets.

<span id="page-16-4"></span>Table 2. Evaluation datasets. We assembled the following set of datasets to evaluate MultiverSeg and baseline methods. For the relative size of datasets, we include the number of unique scans (subject and modality pairs) and labels that each dataset has. These datasets were unseen by MultiverSeg during training. Three datasets were completely held-out from model selection. The validation splits of the other 9 datasets were used for selecting the best model checkpoint. We report final results on the test splits of these 11 datasets.

mentations to create a set of images corresponding to the same synthetic task (Fig. [8\)](#page-18-1).

Given an image  $x_0$ , we first generate a synthetic label  $y_{synth}$  by applying a superpixel algorithm [\[28\]](#page-9-12) with scale parameter  $\lambda \sim U[1, \lambda_{max}]$  to partition the image into a multi-label mask of k superpixels  $z \in \{1, \ldots, k\}^{n \times n}$ . We then randomly select a superpixel  $y_{synth} = 1(z = c)$  as a synthetic label.

To generate a set of  $m + 1$  images representing the same task, we duplicate  $(x_0, y_{synth})$ ,  $m + 1$  times and apply aggressive augmentations to vary the images and segmentation labels [\[16,](#page-8-0) [138\]](#page-14-8).

**Implementation.** MultiverSeg was trained with  $p_{synth}$  = 0.5. We use a superpixel algorithm [\[28\]](#page-9-12) with  $\lambda \sim [1, 500]$ . Tab. [4](#page-18-2) lists the data augmentations.

#### <span id="page-16-0"></span>B.3. Data Augmentation

Tab. [5](#page-19-3) shows the within-task augmentations and taskaugmentations used to train MultiverSeg [\[16,](#page-8-0) [101\]](#page-12-2).

# C. Experimental Setup

## <span id="page-16-1"></span>C.1. Baselines

We provide additional details on the baselines. We summarize the capabilities of our method and baselines in Tab. [6.](#page-20-2)

UniverSeg. Previous work found that ensembling UniverSeg predictions across multiple randomly sampled context sets improved Dice score [\[16\]](#page-8-0). We report results *without* ensembling to accurately reflect the mean Dice of predictions given a fixed size context set.

**OnePrompt.** OnePrompt [\[128\]](#page-13-6) is a medical image segmentation model that can perform in-context segmentation of a target image given a single context example with scrib-

<span id="page-17-1"></span><span id="page-17-0"></span>Table 3. Train datasets. We train MultiverSeg on the following datasets. For the relative size of datasets, we have included the number of unique scans (subject and modality pairs) that each dataset has.

<span id="page-18-1"></span><span id="page-18-0"></span>

Figure 8. Synthetic task generation example. Given an input image, we apply a superpixel algorithm to generate a superpixel map of potential synthetic labels. We randomly sample one of the superpixels to serve as a synthetic label. Next, we duplicate the input image and synthetic label  $m + 1$  times and apply data augmentations (Tab. [4\)](#page-18-2) to vary the examples within the synthetic task. We use the first synthetic example as the target and the remaining  $m$  synthetic examples as the context set during training.

<span id="page-18-2"></span>

<b>Augmentations</b>	$\boldsymbol{p}$	Parameters

<b>Vertical Flip</b>	0.5	None

Table 4. Data augmentations for generating synthetic tasks. Given a set of  $m + 1$  copies of the same example, we randomly sampled data augmentations for each instance to increase the diversity of examples within the task. Each augmentation is sampled with probability  $p$ .

ble, click, bounding box or mask annotation on the context image. OnePrompt can also be used for interactive segmentation by using the same image as both the context image and the target image. We do not compare to OnePrompt because the pre-trained model weights are not publicly available. Recreating the data processing and retraining the model was beyond our computational capacity. For reference, the OnePrompt model required 64 NVIDIA A100 GPUs to train [\[128\]](#page-13-6).

LabelAnything. LabelAnything [\[23\]](#page-9-1) is an in-context segmentation model designed for few-shot multi-label segmentation of natural images. LabelAnything takes as input a target image to segment and a context set of images with multilabel mask, click, or bounding box annotations. We do not compare to LabelAnything because the pre-trained model weights are not publicly available. As with OnePrompt, recreating the data handling and retraining the model from scratch was beyond our computational capacity.

# C.2. Metrics

Averaging. When reporting average performance for a dataset or across multiple datasets, we averaged metrics hierarchically by subject, label, axis, modality, subdataset, and then dataset.

Confidence Intervals. We show 95% confidence intervals from bootstrapping. For experiment 1, we bootstrap over

<span id="page-19-3"></span><span id="page-19-2"></span>

(a) Within-Task Augmentations

(b) Task Augmentations

Table 5. Augmentations used to train MultiverSeg. Within-task data augmentations (top) are randomly sampled for each example within a task to increase the diversity within a task. Task augmentations (bottom) are randomly sampled for each task and then applied to all examples in a task to increase the diversity of tasks. Each augmentation is randomly sampled with probability  $p$ . We apply augmentations after (optional) synthetic task generation and before simulating user interactions.

results from 200 simulations with different random seeds. For experiment 2, we bootstrap over subjects with 100 runs.

# D. Experiment 1: Evaluation

### <span id="page-19-1"></span>D.1. Setup

We illustrate the process of segmenting a set of images using MultiverSeg in Fig. [10](#page-21-0)

Procedure. For all methods, we interactively segment a

<span id="page-19-4"></span>

Figure 9. Examples per task. We visualize the distribution of examples per task in our validation data. We only consider tasks with at least 18 examples in Experiment 1.

seed image to 90% Dice using ScribblePrompt. This first image was randomly sampled (for each simulation round) from the training split. Since the number of interactions and the prediction for this seed image is the same for all methods, we exclude it from the reported results.

We report the number of interactions to achieve 90% Dice for each of the *next* 18 images from the held-out test split of our evaluation tasks. We conduct 200 rounds of simulations, randomly sampling 18 test images (without replacement) from each task and sequentially segmenting them using each method. We use the same random seeds for each method, so the sampled examples are the same across methods for each simulation round.

Tasks. We exclude tasks with fewer than 18 test examples, leaving 59 tasks from 7 evaluation datasets [\[1–](#page-8-11) [3,](#page-8-12) [11,](#page-8-14) [40,](#page-9-10) [118,](#page-13-16) [142\]](#page-14-5). We selected this cutoff based on the distribution of task sizes in our validation data (Fig. [9\)](#page-19-4) to focus on scenarios where a user wants to segment many similar images.

#### <span id="page-19-0"></span>D.2. Results

#### D.2.1. Interactions per image as a function of dataset size

Results by dataset. As more examples are segmented and the context set grows, the number of clicks and scribbles required to get to  $90\%$  Dice on the n<sup>th</sup> example using MultiverSeg decreases substantially. Fig. [11](#page-22-0) shows results averaged by dataset. MultiverSeg and SP+UVS are less effective at reducing the number of clicks for tasks from BUID, a breast ultrasound lesion segmentation dataset, perhaps due to the heterogeneity of examples in that dataset.

Tasks with more examples. We show results by task for two datasets with more than 18 test examples per task (Fig. [12](#page-23-1) and Fig. [13\)](#page-23-2). For larger sets of images, using Multi-

<span id="page-20-2"></span><span id="page-20-1"></span>

Method	Interactive	In-Context	Interactive In-Context
ScribblePrompt [126]			
UniverSeg $[16]$			
LabelAnything [23]			
OnePrompt [128]		$\checkmark$ (context size = 1)	
SP+UVS			
MultiverSeg (ours)			

Table 6. Summary of segmentation methods.

verSeg results in even greater reductions in the total number of user interactions.

Context Set Quality. For MultiverSeg and SP+UVS, thresholding the predictions before adding them to the context set improved performance (Fig. [14\)](#page-24-0). We use the validation split of our validation data to select the best approach (soft or binary predictions in the context set) for each method.

MultiverSeg does not perform well when the context set contains *soft* predictions from previous examples, likely because it was trained with ground truth context labels. The number of interactions to 90% Dice is lowest when the context set contains ground truth labels, however this is not realistic in practice.

SP+UVS. Consistent with the original published results, we find that UniverSeg has poor performance for small context sets and initializing ScribblePrompt using the UniverSeg prediction hurts performance when the context set is small. In our final evaluation of SP+UVS, we set the minimum context set size to be 5 examples: when the context sets contains fewer than 5 examples, we ignore the context and only use ScribblePrompt to make predictions. Fig. [15](#page-24-1) shows variations of SP+UVS with different minimum context set sizes.

Total Interactions. Fig. [16](#page-25-0) shows the total number of interaction steps per set of 18 images by dataset. Tab. [7](#page-25-1) shows the total number of interactions, average Dice score, and average 95th percentile Hausdorff distance across all tasks.

#### <span id="page-20-0"></span>D.2.2. Bootstrapping In-Context Segmentation

Setup. For UniverSeg [\[16\]](#page-8-0), a non-interactive in-context segmentation method, we segment the dataset by bootstrapping from a single context example with ground truth segmentation. For each image in the dataset, we make an incontext prediction and then add the prediction to the context set for the next image until all images in the dataset have been segmented. As an upper bound on performance, we also evaluated using ground truth labels in the context set instead of previously predicted segmentations ("UniverSeg (oracle)").

Results. This approach did not produce accurate results, likely because UniverSeg has poor performance for small context sets and/or context sets with imperfect labels (Fig. [17a\)](#page-26-0). Because UniverSeg does not have a mechanism to incorporate corrections, it was not possible to achieve 90% Dice for most images (Fig. [17b\)](#page-26-0). Fig. [18](#page-26-1) shows results by individual dataset.

Context Set Quality. As with other methods (MultiverSeg and SP+UVS), we experimented with thresholding the predictions at 0.5 before adding them to the context set. For UniverSeg, thresholding the predictions did not improve Dice scores compared to using the soft predictions in the context set.

## E. Experiment 2: Analysis

#### E.1. In-Context Segmentation

Results. Fig. [19](#page-27-0) show results by dataset with different context set sizes.

## E.2. Interactive Segmentation In Context

Results. Fig. [20](#page-28-0) and Fig. [21](#page-29-0) show results by dataset using center clicks and centerline scribbles, respectively.

<span id="page-21-0"></span>

Figure 10. **Example segmentation process with MultiverSeg**. We begin by interactively segmenting a seed image (**Example 0**) to 90% Dice. The Example 0 image and final prediction are added to the context set for subsequent examples. For each subsequent example, we first make an initial in-context segmentation prediction using a context set containing all the previous examples and previously predicted segmentations. Then, we simulate center correction clicks until the predicted segmentation achieves  $\geq 90\%$  Dice or we have accrued 20 clicks. For Example 2, we only simulated 1 correction because the prediction reached 90% Dice after 1 correction click. For Example 1 and Example 3, additional correction clicks were needed. When the context set is large enough  $(>n)$ , the in-context prediction from MultiverSeg may be accurate enough that no corrections are needed. For **Example 10**, the Dice score of the predicted in-context segmentation is greater than  $90\%$  so we do not need to simulate any corrections. In practice, n varies by task.

<span id="page-22-0"></span>

Figure 11. Interactions to target Dice on unseen datasets. Number of interactions needed to reach 90% Dice as a function of the example number being segmented. For the  $n^{th}$  image being segmented, the context set has n examples. MultiverSeg requires substantially fewer interactions to achieve 90 Dice than the baselines, and as more images are segmented, the average number of interactions required decreases dramatically. Shaded regions show 95% CI from bootstrapping.

<span id="page-23-1"></span><span id="page-23-0"></span>

Figure 12. Scribble steps to target Dice by task for BUID. Number of interactions needed to reach a 90% Dice as a function of the example number being segmented. For the  $n^{th}$  image being segmented, the context set has n examples. Shading shows 95% CI from bootstrapping. BUID [\[3\]](#page-8-12) is a breast ultrasound dataset containing segmentation tasks for benign and malignant lesions. As the context set of completed segmentations grows, the number of interactions required to segment each additional image with MultiverSeg declines.

<span id="page-23-2"></span>

Figure 13. Center clicks to target Dice by task for HipXRay. Number of interactions needed to reach 90% Dice as a function of the example number being segmented. For the  $n^{th}$  image being segmented, the context set has n examples. Shading shows 95% CI from bootstrapping. HipXRay [\[40\]](#page-9-10) is an X-Ray dataset with segmentation tasks for the femur and ilium bones. After segmenting a few images from the femur task with MultiverSeg, the rest of the images in the task can be segmented (to  $\geq 90\%$  Dice) with minimal additional interactions.

<span id="page-24-0"></span>

Figure 14. Interactions to target dice on unseen datasets with different types of context sets. Number of interactions needed to reach a 90% Dice as a function of the example number being segmented. For the  $n<sup>th</sup>$  image being segmented, the context set has n examples. We show results with and without thresholding the predictions ("Binary Predictions" vs. "Soft Predictions"). We expect the number of interactions with "Ground Truth" context to be a lower bound on the number of interactions to reach 90% Dice. We show results averaged across validation tasks.

<span id="page-24-1"></span>

Figure 15. Variations of SP+UVS. Number of interactions needed to reach a 90% Dice as a function of the example number being segmented. For the  $n^{th}$  image being segmented, the context set has n examples. We show results for SP+UVS with different minimum context set size cutoffs, along with ScribblePrompt for reference. SP+UVS with a minimum context set size of k, means that when the context set has fewer than  $k$  examples, we perform interactive segmentation with ScribblePrompt (ignoring the context examples). When the context set is larger than the minimum size, we first make an in-context segmentation prediction using UniverSeg and then correct that prediction with ScribblePrompt. For small context set sizes, UniverSeg does not make accurate predictions, and initializing ScribblePrompt with UniverSeg's prediction increases the number of interactions required to reach 90% Dice. We show results averaged across validation tasks.

<span id="page-25-0"></span>

Figure 16. Total interactions per unseen task. We show total number of clicks and scribble steps to segment 18 images to  $\geq 90\%$  Dice for each method. In all scenarios, MultiverSeg required fewer interactions than both baselines. Error bars show 95% CI from bootstrapping.

<span id="page-25-1"></span>

<b>Interaction Protocol</b>	Method	Dice Score $\uparrow$	HD95 $\downarrow$	Total Steps $\downarrow$
<b>Center Clicks</b>	ScribblePrompt	$91.23 \pm 0.08$	$1.04 \pm 0.02$	$131.03 \pm 1.32$
	SP+UVS	$91.14 \pm 0.11$	$1.07 \pm 0.03$	$115.30 \pm 2.34$
	MultiverSeg (ours)	$91.35\pm0.21$	$1.00\pm0.04$	$84.39 \pm 2.58$
Centerline Scribbles	ScribblePrompt	$93.23 \pm 0.21$	$0.90 \pm 0.10$	$55.27 \pm 3.28$
	SP+UVS	$93.22 \pm 0.20$	$0.90 \pm 0.12$	$42.77 \pm 2.75$
	MultiverSeg (ours)	$93.23 \pm 0.21$	$0.86\pm0.10$	$26.13 \pm 2.39$

Table 7. Average segmentation quality and total interactions per unseen task. We measure average segmentation quality across a set of 18 test images using Dice score and 95th percentile Hausdorff distance (HD95). For each metric, we show mean and standard deviation from bootstrapping. Dice and HD95 are similar across methods because we simulate interactions until the predicted segmentation has  $\geq 90\%$  Dice or the maximum number of interaction steps is reached. MultiverSeg requires the fewest interaction steps per task on average.

<span id="page-26-0"></span>

Method	Dice Score $\uparrow$	No. Failures $\downarrow$
UniverSeg	$51.02 \pm 0.07$	$16.60 \pm 0.44$
UniverSeg (oracle)	$70.24 \pm 0.13$	$13.28 \pm 0.28$

(a) Dice score by example number. We show average Dice Score across unseen test data by example number. We exclude the initial seed example, such that for the  $n<sup>th</sup>$  image being segmented, the context set has *n* examples.

(b) Average performance on unseen tasks. We report average Dice score per task of 18 images and the average number of examples where the Dice score was less than 90%. We report standard deviation across 200 simulations.

Figure 17. Bootstrapping UniverSeg. We use UniverSeg to sequentially segment images starting from a single example with a ground truth segmentation. After segmenting each image, the image and predicted segmentation are added to the context set for the next example. For the "oracle" version, we use ground truth labels in the context set instead of previously predicted segmentations. Even when using ground truth labels in the context set, which we expect to be an upper bound on performance, it was not possible to achieve 90% Dice for most images.

<span id="page-26-1"></span>

Figure 18. Bootstrapping UniverSeg results by dataset. We show Dice score vs. example number for unseen tasks averaged by dataset. After segmenting each image, the image and predicted segmentation are added to the context set for the next example. For the "oracle" version, we use ground truth labels in the context set instead of previously predicted segmentations. We exclude the initial seed example, such that for the  $n<sup>th</sup>$  image being segmented, the context set has n examples. Shaded regions show 95% CI from bootstrapping.

<span id="page-27-0"></span>

Figure 19. In-context segmentation performance across context set sizes on unseen datasets. We compare MultiverSeg to UniverSeg, an in-context segmentation method, given ground truth context labels. Shading shows 95% CI from bootstrapping.

<span id="page-28-0"></span>

Figure 20. Interactive segmentation in context with center clicks on unseen datasets. MultiverSeg's interactive segmentation performance with the same number of interactions improves as the context set size grows. We first make an initial prediction based on the context set (step 0), and then simulate corrections with one center click at a time. Shading shows 95% CI from bootstrapping.

<span id="page-29-0"></span>

Figure 21. Interactive segmentation in context with centerline scribbles on unseen datasets. MultiverSeg's interactive segmentation performance with the same number of interactions improves as the context set size grows. We first make an initial prediction based on the context set (step 0), and then simulate centerline scribble corrections. Shading shows 95% CI from bootstrapping.
