SIFTED DEGREES OF THE EQUATIONS OF THE REES MODULE AND THEIR CONNECTION WITH THE ARTIN-REES NUMBERS.

PHILIPPE GIMENEZ AND FRANCESC PLANAS-VILANOVA

ABSTRACT. Let A be a noetherian ring, I an ideal of A and $N \subset M$ finitely generated Amodules. The relation type of I with respect to M, denoted by $\mathbf{rt}(I;M)$, is the maximal degree in a minimal generating set of relations of the Rees module $\mathbf{R}(I;M) = \bigoplus_{n \geq 0} I^n M$. It is a well-known invariant that gives a first measure of the complexity of $\mathbf{R}(I;M)$. To help to measure this complexity, we introduce the sifted type of $\mathbf{R}(I; M)$, denoted by $\mathbf{st}(I;M)$, a new invariant which counts the non-zero degrees appearing in a minimal generating set of relations of $\mathbf{R}(I;M)$. Just as the relation type $\mathbf{rt}(I;M/N)$ is closely related to the strong Artin-Rees number $s(N, M; I)$, it turns out that the sifted type $\mathbf{st}(I;M/N)$ is closely related to the medium Artin-Rees number $\mathbf{m}(N,M;I)$, a new invariant which lies in between the weak and the strong Artin-Rees numbers of $(N, M; I)$. We illustrate the meaning, interest and mutual connection of $\mathbf{m} (N, M; I)$ and $\mathbf{st} (I; M)$ with some examples.

PREAMBLE

The Rees algebra and the other so-called blowing-up algebras have been present in some way, centrally or collaterally, in many of Wolmer V. Vasconcelos' publications, both articles and books, since the early 1980s, when he began his long and very fruitful collaboration with Aron Simis. They are the authors with Jürgen Herzog of the foundational papers [\[17,](#page-19-0) [18,](#page-19-1) [19\]](#page-19-2) and, together with other relevant and influential algebrists, they located the study of these algebras as a central topic of Commutative Algebra. The two authors of the present note have learned about Rees algebras (and many other topics) mainly by reading Wolmer's contributions and from many stimulating conversations with

Keywords: Artin-Rees number, relation type, Rees algebra, Rees module.

him over 3 decades after they had the opportunity to meet him (and each other) in Trieste in 1992. We would like to thank the editors of this volume, and especially Aron Simis, for being so patient in waiting for this contribution and for giving us the opportunity, by paying tribute to Wolmer, to work together after more than 30 years of friendship.

This is for him, this paper is dedicated to the memory of Wolmer V. Vasconcelos.

1. INTRODUCTION

Given a noetherian ring A and an ideal I in A, the Rees algebra of I is the subring $\mathbf{R}(I) = \bigoplus_{n \geq 0} I^n t^n$ of the polynomial ring $A[t]$. It provides an algebraic realization of the notion of blowing-up a variety along a subvariety and hence plays an important role in the theory of singularities in algebraic geometry. From an algebraic point of view, it is an ubiquitous object linked to many constructions and problems in commutative algebra. It is related to the symmetric algebra $S(I)$ of I through the graded canonical surjection $\alpha : \mathbf{S}(I) \to \mathbf{R}(I)$. While the symmetric algebra takes care of the linear relations among the generators of the ideal I , i.e., its first syzygies, the Rees algebra takes care of all their homogeneous relations, i.e., as Vasconcelos claims in [\[55,](#page-21-0) p. 195], the first syzygies of all the powers of I. More precisely, if the ideal I of A is generated by x_1, \ldots, x_n , one can consider the surjection φ from the ring of polynomials $A[X_1, \ldots, X_n]$ onto $\mathbf{R}(I)$ defined by $X_i \mapsto x_i t$. The elements in ker(φ) are called the equations of the Rees algebra $\mathbf{R}(I)$. The maximal degree in a minimal generating set of ker(φ) is called the relation type of I and denoted by $\mathbf{rt}(I)$. It does not depend on the choosen generating set of I; see, e.g., [\[39,](#page-20-0) [44,](#page-20-1) [55,](#page-21-0) [59\]](#page-21-1). The description of $\ker(\varphi)$ is, in general, a difficult problem. In this sense, the relation type gives a first measure of the complexity of the problem of describing the equations of the Rees algebra. To complement the information given by the relation type, we introduce a second measure which is the number of non-zero degrees in a minimal generating set of ker(φ). We call this new invariant the *sifted type of* I, and we denote it by $st(I)$. One would like to know $rt(I)$ and $st(I)$ before determining the equations of the Rees algebra of I.

From this point of view, the simplest ideals are those whose relation type (and sifted type) is equal to 1. Note that an ideal I has relation type 1 if and only if the canonical morphism $\alpha : \mathbf{S}(I) \to \mathbf{R}(I)$ is an isomorphism. These ideals are said to be of linear type. According to [\[55,](#page-21-0) p. 30], the terminology was introduced by Robbiano and Valla. Ideals of linear type have been extensively studied in the 1980s [\[6,](#page-19-3) [7,](#page-19-4) [17,](#page-19-0) [18,](#page-19-1) [19,](#page-19-2) [20,](#page-19-5) [21,](#page-19-6) [27,](#page-20-2) [50,](#page-21-2) [53\]](#page-21-3) but the first important family of ideals of linear type is already given by Micali in the early 1960s [\[30,](#page-20-3) [31\]](#page-20-4): if I is a generated by a regular sequence, then it is of linear type. In [\[20\]](#page-19-5) Huneke introduces the notion of d-sequence, a weaker condition to that of regular sequence, and shows that an ideal generated by a d-sequence is of linear type, a result proved simultaneously by Valla in [\[53\]](#page-21-3). Other classes of ideals with low relation type have been studied. For example, the notion of quadratic sequence is introduced in [\[44\]](#page-20-1) where ideals generated by such a sequence are shown to have relation type 2. On the other hand, an ideal I is said to be syzygetic if $\alpha_2 : \mathbf{S}_2(I) \to I^2$ is an isomorphism. This is a strictly weaker condition to that of being of linear type. Syzygetic ideals were introduced in [\[32\]](#page-20-5) and have been studied, e.g., in $[2, 16, 17, 18, 47]$ $[2, 16, 17, 18, 47]$ $[2, 16, 17, 18, 47]$ $[2, 16, 17, 18, 47]$ $[2, 16, 17, 18, 47]$. Describing the syzygetic condition we have, e.g., the following two results: if R is local of depth 2 and I is an ideal of heigth 2 and projective dimension one, then I is syzygetic if and only if I is generated by a regular sequence of two elements [\[18,](#page-19-1) Proposition 2.7]; if R is regular local, with $1/2 \in R$, then a Gorenstein ideal of height 3 is syzygetic [\[18,](#page-19-1) Proposition 2.8]. (See [\[42,](#page-20-6) Lemma 2.1] for a recent generalization of this result.)

There are several powerful and efficient tools to obtain some equations of the Rees algebra, though very rarely they provide the whole generating set of its equations. The socalled Jacobian dual is one of these tools. It already appears in [\[54\]](#page-21-5) (see also [\[55,](#page-21-0) Chapter 8) for ideals and has been further developed for modules in $|46|$. It works as follows: if J is the $n \times r$ matrix of the first syzygies of $I = \langle x_1, \ldots, x_n \rangle$ and if $\varphi : A[X_1, \ldots, X_n] \to \mathbf{R}(I)$ is a polynomial presentation of $\mathbf{R}(I)$ with $L := \text{ker}(\varphi)$, then L_1 is generated by the entries of the matrix $(X_1 \cdots X_n) \cdot J$. If $a = \langle a_1, \ldots, a_d \rangle$ is an ideal of A containing all the entries of J , one can also write these generators of L_1 as the entries of the matrix $\left(a_1 \cdots a_n\right) \cdot B(J)$, for some non-unique $d \times r$ matrix $B(J)$. In other words, one can think of J and $B(J)$ as the Jacobian matrices of the ideal L_1 with respect to the "variables" X_1, \ldots, X_n and a_1, \ldots, a_d respectively. Using Cramer's rule, it is easy to show that the Fitting ideal $I_r(B(J))$ is contained in L. Thus, one gets equations of the Rees algebra using this simple technique. When $L = \langle L_1, I_r(B(J)) \rangle$, the ideal I is said to have the expected equations [\[58,](#page-21-7) Definition 1.8]. This has been studied for ideals of small codimension in [\[33\]](#page-20-7). See also [\[12\]](#page-19-9) for a successful application of this technique to describe the entire Rees algebra.

As mentioned before, the relation type of an ideal I, combined with its sifted type, is a measure of the complexity in describing the equations of its Rees algebra and, hence, it can also be seen as a measure of the complexity of the ideal I itself. This also occurs with the Castelnuovo-Mumford regularity of I , which measures the difficulty in constructing the syzygies (of any order) of I , and hence guesses the degree of complexity of I . For the connection between the relation type and the Castelnuovo-Mumford regularity, as well as their relationship with other invariants, see, e.g., [\[3,](#page-19-10) [13,](#page-19-11) [25,](#page-20-8) [26,](#page-20-9) [34,](#page-20-10) [39,](#page-20-0) [43,](#page-20-11) [51,](#page-21-8) [52,](#page-21-9) [57\]](#page-21-10). It is also worth mentioning that the equations of the Rees algebra are involved in some of the examples constructed in [\[29\]](#page-20-12) to refute the challenging Eisenbud-Goto regularity conjecture.

The Rees algebra $\mathbf{R}(I)$ is also involved in the simple proof of the Artin-Rees Lemma for ideals given in [\[56,](#page-21-11) Theorem. A.1.6]. Recall that the general version of the Artin-Rees Lemma for modules states that, for any ideal I in A and any two finitely generated A modules $N \subseteq M$, there exists an integer $s \geq 1$ such that, $I^nM \cap N = I^{n-s}(I^sM \cap N)$, for all $n \geq s$. The notion of Rees module $\mathbf{R}(I;M) = \bigoplus_{n \geq 0} I^n M$ of an ideal I with respect to a module M can be used in the proof of this result (see, e.g., [\[41,](#page-20-13) Lemma 1.1]). There is a well-known connection between the Artin-Rees Lemma and the relation type, which roughly speaking establishes that the aforementioned integer s linked to the triple $(N, M; I)$ is bounded above by the relation type of the Rees module $\mathbf{R}(I; M/N)$ (see, e.g., [\[18,](#page-19-1) [20,](#page-19-5) [21,](#page-19-6) [28,](#page-20-14) [41,](#page-20-13) [59\]](#page-21-1) and, in particular, [\[40,](#page-20-15) Theorem 2]). We would like to mention that in [\[18\]](#page-19-1), the authors observe how being of linear type gives the Artin-Rees Lemma 'on the nose' as already observed in [\[21\]](#page-19-6) for ideals generated by a d-sequence.

The Artin-Rees Lemma has raised many relevant questions of a uniform nature. The pair of finitely generated A-modules (N, M) with $N \subseteq M$ is said to have the strong uniform Artin–Rees property if there exists an integer $s \geq 1$ (depending on M and N), such that for all $n \geq s$ and all ideals $I, I^nM \cap N = I^{n-s}(I^sM \cap N)$. In [\[10\]](#page-19-12), Eisenbud and Hochster ask if, when A is an affine ring, any pair (N, M) has the strong uniform Artin–Rees property with respect to maximal ideals (i.e., restricting the property to all maximal ideals of A). This question has been answered by Duncan and O'Carroll in $[9]$ when A is an excellent ring. Previously, O'Carroll has shown in [\[35\]](#page-20-16) that if A is an excellent ring, any pair (N, M) has the weak uniform Artin–Rees property with respect to maximal ideals, where the weak uniform property asks for the weakest condition $I^nM\cap N\subseteq I^{n-s}N$. The same author showed later on in [\[36\]](#page-20-17) (see also [\[37\]](#page-20-18)) that over an arbitrary noetherian ring A, any pair (N, M) has the strong Artin-Rees uniform property with respect to principal ideals: there exists an integer $s \geq 1$ such that for all $n \geq s$ and all $x \in A$, $x^n M \cap N = x^{n-s}(x^s M \cap N)$. Inspired by these results, Huneke proves in [\[22\]](#page-19-14) several kinds of uniform behaviour and conjectures that excellent noetherian rings of finite Krull dimension have the weak uniform Artin-Rees property (see also [\[23\]](#page-20-19) and [\[49\]](#page-21-12)). For the uniform Artin-Rees property with respect to prime ideals, see [\[38\]](#page-20-20). With respect to the whole set of ideals of A, see [\[40\]](#page-20-15) (and also [\[48\]](#page-21-13)). Going back to the Rees algebra, a uniform property of the relation type is raised by Huneke: if A is a complete local equidimensional noetherian ring, does there exist a uniform number N such that for any ideal I generated by a system of parameters, $\mathbf{rt}(I) \leq N$? Partial positives answers to this question are given in [\[1,](#page-18-0) [28,](#page-20-14) [59,](#page-21-1) [60\]](#page-21-14).

In this note, we focus on the relationship between the Artin-Rees numbers and the degrees of the defining equations of the Rees module of an ideal with respect to a module. Associated to a triple $(N, M; I)$ formed by two finitely generated modules $N \subseteq M$ and an ideal I, there are two known invariants, the strong and the weak Artin-Rees numbers. In Section [2,](#page-5-0) we recall the definitions of these two invariants and introduce the *medium Artin-Rees number*, a new invariant located between the weak and the strong Artin-Rees numbers (Proposition [2.1\)](#page-6-0). On the other hand, we recall the definition of the relation type of an ideal I with respect to a module P, and introduce the *sifted type of* I *with respect to* P, a smaller invariant. These five invariants are related in Theorem [2.6.](#page-9-0) In Section [3,](#page-10-0) we give several families of examples to illustrate the behaviour of these invariants. In Section [4,](#page-14-0) we focus on the case of a polynomial ideal I in 2 variables minimally generated by 3 monomials of the same degree with no common factor. We take advantage of the minimal bigraded free resolution of $R(I)$ constructed in [\[5\]](#page-19-15), to compute the values of the relation type and the sifted type of I (Proposition [4.1\)](#page-14-1). (For a very recent generalization of [\[5\]](#page-19-15), see [\[24\]](#page-20-21), where the three monomials can have different degrees). Proposition [4.1](#page-14-1) allows us to give several interesting examples, where the difference between the relation type and the sifted type can be arbitrarily large. In particular, as a consequence of Example [4.7,](#page-17-0) we deduce that, given any integer ℓ , we can easily obtain an ideal of sifted degree equal to ℓ . Finally, in Section [5](#page-17-1) we revisit three classical examples to stand out their sifted type and relation type.

We are aware that the list of references included here is by no means exhaustive, it is just a brief selection limited by our knowledge and time frame.

2. SOME INVARIANTS LINKED TO THE TRIPLE $(N, M; I)$.

Let A be a noetherian ring, I an ideal of A, and $N \subseteq M$ finitely generated A-modules. Let us recall (as well as introduce) the definition of some (new) invariants associated to these modules and to the ideal I (see, e.g., [\[18\]](#page-19-1), [\[20\]](#page-19-5), [\[41\]](#page-20-13) and the references there-in).

For ease of further reference, we denote and call the *n*-th Artin-Rees module, $n \geq 1$, the quotient:

$$
E(N, M; I)_n \stackrel{\text{def}}{=} (I^n M \cap N) / I(I^{n-1} M \cap N).
$$

Associated to the triple $(N, M; I)$ we have the following three invariants.

• The strong Artin-Rees number $s(N, M; I)$.

The Artin-Rees Lemma states that there exists an integer $s \geq 1$ such that

$$
I^{n}M \cap N = I^{n-s}(I^{s}M \cap N), \text{ for all } n \ge s. \tag{2.1}
$$

In particular, for all $n \ge t \ge s$,

$$
I^{n}M \cap N = I^{n-s}(I^{s}M \cap N) = I^{n-t}(I^{t-s}(I^{s}M \cap N)) = I^{n-t}(I^{t}M \cap N).
$$

Thus, if the equality [\(2.1\)](#page-5-1) holds for $s \geq 1$, then it also holds for any $t \geq s$. Hence, it is natural to define the strong Artin-Rees number of $(N, M; I)$ as:

$$
\begin{array}{rcl}\n\mathbf{s}(N, M; I) & \stackrel{\text{def}}{=} & \min\{s \ge 1 \mid I^n M \cap N = I^{n-s}(I^s M \cap N), \text{ for all } n \ge s\} \\
& = & \min\{s \ge 1 \mid I^n M \cap N = I(I^{n-1} M \cap N), \text{ for all } n \ge s+1\} \\
& = & \min\{s \ge 1 \mid E(N, M; I)_n = 0, \text{ for all } n \ge s+1\}.\n\end{array}
$$

• The weak Artin-Rees number $\mathbf{w}(N, M; I)$.

As a consequence of the Artin-Rees Lemma, one deduces that there exists an integer $s \geq 1$ such that $I^nM \cap N \subseteq I^{n-s}N$ for all $n \geq s$. In particular, for all $n \geq t \geq s$,

$$
I^n M \cap N \subseteq I^{n-s} N \subseteq I^{n-t} N.
$$

Thus, $I^n M \cap N \subseteq I^{n-t}N$, for all $n \geq t$. The weak Artin-Rees number is then defined as:

$$
\mathbf{w}(N, M; I) \stackrel{\text{def}}{=} \min\{s \ge 1 \mid I^n M \cap N \subseteq I^{n-s}N \text{ for all } n \ge s\}.
$$

• The medium Artin-Rees number $m(N, M; I)$.

In between the strong and the weak Artin-Rees numbers, we consider a new invariant, the *medium Artin-Rees number*, defined as follows:

$$
\mathbf{m}(N, M; I) \stackrel{\text{def}}{=} 1 + \text{card} \{ n \ge 2 \mid E(N, M; I)_n \ne 0 \}.
$$

Proposition 2.1.

$$
\mathbf{w}(N, M; I) \le \mathbf{m}(N, M; I) \le \mathbf{s}(N, M; I).
$$

Proof. Note that, if $s(N, M; I) = r$, $r \geq 1$, then $E(N, M; I)_n = 0$, for all $n \geq r + 1$. Thus, the set of indices $n \geq 2$ with $E(N, M; I)_n \neq 0$ is included in $\{2, \ldots, r\}$. Therefore, $$

Now, let us prove that $\mathbf{w}(N, M; I) \leq \mathbf{m}(N, M; I)$. Observe that, if for a given pair of integers $n > m \ge 1$, $E(N, M; I)_{m+1} = ... = E(N, M; I)_n = 0$, then

$$
I^{n}M \cap N = I(I^{n-1}M \cap N) = \dots = I^{n-m}(I^{m}M \cap N) \subseteq I^{n-m}(I^{m-1}M \cap N). \tag{2.2}
$$

If $m(N, M; I) = 1$, then $E(N, M; I)_n = 0$, for all $n \ge 2$. Using [\(2.2\)](#page-6-1), with $m = 1$, we get $I^n M \cap N \subseteq I^{n-1}N$, for all $n \ge 2$, so $\mathbf{w}(N, M; I) \le 1 = \mathbf{m}(N, M; I)$.

Suppose that $\mathbf{m}(N, M; I) = r \geq 2$. Then, there exist $2 \leq m_2 < \ldots < m_r$ with $E(N, M; I)_{m_i} \neq 0$, for $i = 2, \ldots, r$, and such that $E(N, M; I)_n = 0$, for all $n \geq 2$, $n \notin \{m_2, \ldots, m_r\}$. Let $n \geq r$. If $2 \leq n \leq m_2$, then, for all $2 \leq m \leq n$, $E(N, M; I)_m = 0$, so $I^nM\cap N = I^{n-1}(IM\cap N)$. In particular, $I^nM\cap N \subseteq I^{n-1}N \subseteq I^{n-r}N$. If $m_2 \le n < m_3$, using twice (2.2) , we get:

$$
I^{n}M \cap N = I^{n-m_2}(I^{m_2}M \cap N) \subseteq I^{n-m_2}(I^{m_2-1}M \cap N)
$$

=
$$
I^{n-m_2}(I^{m_2-2}(IM \cap N)) = I^{n-2}(IM \cap N).
$$

In particular, $I^n M \cap N \subseteq I^{n-2}N \subseteq I^{n-r}N$. Suppose that $m_{r-1} \leq n \langle m_r$. As before, using [\(2.2\)](#page-6-1), and by induction,

$$
I^{n}M \cap N = I^{n-m_{r-1}}(I^{m_{r-1}}M \cap N) \subseteq I^{n-m_{r-1}}(I^{m_{r-1}-1}M \cap N)
$$

$$
\subseteq I^{n-m_{r-1}}(I^{m_{r-1}-(r-1)}(IM \cap N)) = I^{n-(r-1)}(IM \cap N). \quad (2.3)
$$

In particular, $I^n M \cap N \subseteq I^{n-(r-1)}N \subseteq I^{n-r}N$. Finally, suppose that $n \geq m_r$. Again, using (2.2) and (2.3) , we deduce

$$
I^n M \cap N = I^{n-m_r}(I^{m_r} M \cap N) \subseteq I^{n-m_r}(I^{m_r-1} M \cap N)
$$

$$
\subseteq I^{n-m_r}(I^{(m_r-1)-(r-1)}(I M \cap N)) = I^{n-r}(I M \cap N).
$$

Therefore, $I^n M \cap N \subseteq I^{n-r}N$, for all $n \ge r$, so $\mathbf{w}(N, M; I) \le \mathbf{m}(N, M; I)$.

Now we turn to relate these Artin-Rees numbers with the degrees of the equations of the Rees modules. Let $S(I)$ be the symmetric algebra of I. Given a finitely generated A-module P, consider the Rees module $\mathbf{R}(I;P) = \bigoplus_{n\geq 0} I^n P$ of I with respect to P. Let $\alpha : \mathbf{S}(I) \to \mathbf{R}(I)$ be the canonical graded surjective morphim from the symmetric algebra of I to the Rees algebra of I. Let $\pi : \mathbf{R}(I) \otimes P \to \mathbf{R}(I; P)$ be the natural graded surjective morphim of graded $S(I)$ -modules, given by the surjection $I^n \otimes P \to I^n P$. Then,

$$
\gamma: \mathbf{S}(I) \otimes P \xrightarrow{\alpha \otimes 1} \mathbf{R}(I) \otimes P \xrightarrow{\pi} \mathbf{R}(I;P)
$$

is a surjective graded morphism of graded $S(I)$ -modules. The module of effective *n*relations of I with respect to P, $n \geq 2$, is defined as

$$
E(I;P)_n \stackrel{\text{def}}{=} \ker(\gamma_n)/\mathbf{S}_1(I) \cdot \ker(\gamma_{n-1}),
$$

where $\gamma_n : \mathbf{S}_n(I) \otimes P \to I^nP$ stands for the *n*-th graded component of γ .

If ρ : $\mathbf{S}(F) \otimes G \to \mathbf{R}(I;P)$ is any other symmetric presentation (e.g., F and G free modules), then one can show that $\ker(\rho_n)/\mathbf{S}_1(F) \cdot \ker(\rho_{n-1})$ is isomorphic to $E(I;P)_n$ (see, e.g., [\[40,](#page-20-15) Lemma 2.3 and Definition 2.4]). Thus, $E(I; P)_n$ describes all those relations of degree n of $\mathbf{R}(I;P)$ which can not be obtained by relations of lower degree. If $P = A$, we just write $E(I)$ for $E(I;A)$.

The next result links effective relations with Artin-Rees modules.

Proposition 2.2. For each $n \geq 2$, we have the short exact sequence of A-modules:

$$
E(I;M)_n \to E(I;M/N)_n \stackrel{\varphi}{\to} E(N,M;I)_n \to 0. \tag{2.4}
$$

If I is generated by the elements x_1, \ldots, x_r , then the morphism φ sends the class of an ef $fective~n\text{-}relation\sum_{|\alpha|=n} \overline{m}_{\alpha}T^{\alpha}\in M/N[T_1\ldots,T_r]$ *to the class of the element* $\sum_{|\alpha|=n} m_{\alpha}x^{\alpha}$ *in the module* $E(N, M; I)_n = (I^n M \cap N) / I(I^{n-1} M \cap N)$.

Proof. The existence of the exact sequence follows from [\[40,](#page-20-15) Lemma 2.3 and Theorem 2] or [\[41,](#page-20-13) Section 6]. To calculate the image of an element of $E(I; M/N)_n$ in $E(N, M; I)_n$, just trace back the definition of the morphism φ in [\[40,](#page-20-15) Lemma 2.3].

In connection with the degrees of the effective relations, one has two invariants. The first one is classical, while the second is new.

• The relation type $\mathbf{rt}(I;P)$ of I with respect to P.

The relation type of I with respect to P can be defined as

$$
\mathbf{rt}(I;P) \stackrel{\text{def}}{=} \min\{r \ge 1 \mid E(I;P)_n = 0, \text{ for all } n \ge r+1\}.
$$

So, $\mathbf{rt}(I; P)$ is the maximum degree in a minimal generating set of relations of the Rees module $\mathbf{R}(I;P)$. If $P = A$, we just write $\mathbf{rt}(I)$ for $\mathbf{rt}(I;A)$. From the exact sequence (2.4) , one easily deduce the inequalities (see [\[40,](#page-20-15) Theorem 2]):

$$
\mathbf{s}(N, M; I) \le \mathbf{rt}(I; M/N) \le \max(\mathbf{rt}(I; M), \mathbf{s}(N, M; I)).
$$
\n(2.5)

• The sifted type $st(I; P)$ of I with respect to P.

The set $SD(I; P)$ of sifted degrees of I with respect to P is defined as the set of integers

SD
$$
(I; P)
$$
 $\stackrel{\text{def}}{=} \{1\} \cup \{n \ge 2 \mid E(I; P)_n \ne 0\}.$

The *sifted type of* I *with respect to* P is defined as

$$
\mathbf{st}(I;P) \stackrel{\text{def}}{=} \operatorname{card}(\operatorname{SD}(I;P)) = 1 + \operatorname{card} \{ n \ge 2 \mid E(I;P)_n \ne 0 \}.
$$

We add the integer 1 in $SD(I; P)$ to count the possible non-zero syzygies of IP, which can be seen as the relations of degree 1. Even if there are no relations in degree 1, we want st $(I; P)$, as well as $\text{rt}(I; P)$, to be at least 1. As before, if $P = A$, then we just write $SD(I)$ and $st(I)$.

From the definition and the exact sequence (2.4) , it is readily seen that:

Lemma 2.3.

$$
\mathbf{st}(I;P) \leq \mathbf{rt}(I;P).
$$

Proof. Suppose that $\text{rt}(I; P) = r$. Then $E(I; P)_n = 0$, for all $n \geq r + 1$. Hence, SD $(I; P) \subseteq \{1, ..., r\}$, st $(I; P) \le r$ and st $(I; P) \le rt(I; P)$.

In an analogy to [\[40,](#page-20-15) Theorem 2], recalled previously in [\(2.5\)](#page-8-0), we have the following result.

Proposition 2.4.

 $m(N, M; I) \leq st (I; M/N) \leq st (I; M) + m (N, M; I) - 1.$

Proof. Let $\text{st}(I; M/N) = r$, where $SD(I; M/N) = \{1, m_2, \ldots, m_r\}, 1 < m_2 < \ldots < m_r$. Using the exact sequence [\(2.4\)](#page-7-0), we deduce that $E(N, M; I)_n = 0$, for all $n \geq 2$, $n \notin$ ${m_2, \ldots, m_r}$. Therefore, $\mathbf{m}(N, M; I) \leq 1 + (r - 1) = r = \mathbf{st}(I; M/N)$.

Now, let $\mathbf{st}(I; M) = s$, so $SD(I; M) = \{1, n_2, ..., n_s\}$, for some $1 < n_2 < ... < n_s$. Let $\mathbf{m}(N, M; I) = t$. Thus, there are $2 \le m_2 < \ldots < m_t$ such that $E(N, M; I)_{m_j} \neq 0$, for $j =$ 2, . . . , t, and $E(N, M; I)_m = 0$, for all $m \geq 2$, $m \notin \{m_2, \ldots, m_t\}$. Using the exact sequence [\(2.4\)](#page-7-0), we deduce that $E(I; M/N)_n = 0$, for all $n \geq 2$, $n \notin \{n_2, \ldots, n_s\} \cup \{m_2, \ldots, m_t\}.$ Therefore, $\mathbf{st}(I; M/N) \leq 1 + (s - 1) + (t - 1) = \mathbf{st}(I; M) + \mathbf{m}(N, M; I) - 1.$

A special case takes place when I is an ideal of linear type with respect to M , i.e., when $\mathbf{rt}(I;M) = 1$ (see, e.g., [\[18\]](#page-19-1)).

Proposition 2.5. Let I be an ideal of linear type with respect to M. Then $E(I; M/N)_n =$ $E(N, M; I)_n$, for all $n \geq 2$. In particular, $\mathbf{s}(N, M; I) = \mathbf{rt}(I; M/N)$ and $\mathbf{m}(N, M; I) =$ $st (I; M/N)$.

Proof. Indeed, by hypothesis, $E(I; M)_n = 0$, for all $n \geq 2$. Using the exact sequence [\(2.4\)](#page-7-0), we deduce that $E(I; M/N)_n = E(N, M; I)_n$, for all $n \ge 2$. Hence,

$$
\begin{aligned}\n\text{rt}(I; M/N) &= \min\{r \ge 1 \mid E(I; M/N)_n = 0, \text{ for all } n \ge r + 1\} \\
&= \min\{r \ge 1 \mid E(N, M; I)_n = 0, \text{ for all } n \ge r + 1\} = \textbf{s}(N, M; I) \text{ and} \\
\text{st}(I; M/N) &= 1 + \text{card}\{n \ge 2 \mid E(I; M/N)_n \ne 0\} \\
&= 1 + \text{card}\{n \ge 2 \mid E(N, M; I)_n \ne 0\} = \textbf{m}(N, M; I).\n\end{aligned}
$$

Summarizing the previous results, we have the following:

Theorem 2.6. *If* A *is a noetherian ring, for any ideal* I *in* A *and any pair of finitely generated* A-modules $N \subseteq M$, the following diagram of inequalities holds:

$$
\mathbf{w}(N, M; I) \leq \mathbf{m}(N, M; I) \leq \mathbf{s}(N, M; I)
$$

$$
\begin{array}{rcl}\nN & \mathbf{s}(N, M; I) \\
\mathbf{st}(I; M/N) & \leq \mathbf{rt}(I; M/N).\n\end{array}
$$

Before finishing the section we emphasize the following fact.

Remark 2.7. The notion of a module of effective relations, as well as its linked concepts of relation type and sifted type, can readily be extended to any standard module (see, e.g., citegp or [\[40\]](#page-20-15)). It is of great interest to consider the associated graded module $\mathbf{G}(I;M) = \bigoplus_{n\geq 0} I^n M/I^{n+1}M$ of an ideal I of A with respect to an A-module M and its module of effective *n*-relations $E(G(I;M))_n$. It is shown that, for every $n \geq 2$, there is an exact sequence of A-modules (see [\[39,](#page-20-0) Proposition 3.3] or [\[13,](#page-19-11) Proposition 3.2]):

$$
E(I;M)_{n+1} \xrightarrow{\psi_n} E(I;M)_n \to E(\mathbf{G}(I;M))_n \to 0.
$$
 (2.6)

If I is generated by x_1, \ldots, x_r , then the morphism ψ_n sends the class of an effective relation $\sum_{|\alpha|=n+1} m_{\alpha} T^{\alpha}$ in $M[T_1 \ldots, T_r]$ to the class of the element $\sum_{|\alpha|=n+1} x_i m_{\alpha} T^{\alpha_i}$ in the module $E(M; I)_n$, where T_i divides T^{α} and $T^{\alpha_i} := T^{\alpha}/T_i$ (see the downgrading morphism in $|18|$).

From the exact sequence [\(2.6\)](#page-10-1), one deduces that $\mathbf{rt}(\mathbf{G}(I;M)) = \mathbf{rt}(I;M)$ (see [\[39,](#page-20-0) Proposition 3.3 and [\[40,](#page-20-15) Remark 2.7]). Hence, it is natural to ask whether $st(G(I;M))$ is equal to $\mathbf{st} (I; M)$. We see in Example [3.1](#page-10-2) that the answer is negative in general.

3. First Examples

In this section we give some simple examples. We begin by showing that $st(G(I;M))$ might be strictly smaller than $st(I;M)$.

Example 3.1. Let $I = (a)$ be a principal ideal of a noetherian local ring A and let M be a finitely generated A-module. Then, $E(I;M)_n = (0: a^n)/(0: a^{n-1})$, where the colon module is defined as $(0: a^n) := \{x \in M \mid a^n x = 0\}$. In particular, if $E(I; M)_n = 0$, then $E(I;M)_m = 0$, for all $m \ge n$. Hence, $st(I;M) = rt(I;M)$.

Note that the morphism $\psi_n : E(I;M)_{n+1} \to E(I;M)_n$ defined in [\(2.6\)](#page-10-1) sends the class of an element $x \in (0 : a^{n+1})$ to the class of ax in $E(I; M)_n = (0 : a^n)/(0 : a^{n-1})$. Thus, the image of $E(I;M)_{n+1}$ through ψ_n is

$$
\psi_n(E(I;M)_{n+1}) = \frac{a(0:a^{n+1}) + (0:a^{n-1})}{(0:a^{n-1})} \subseteq \frac{(0:a^n)}{(0:a^{n-1})} = E(I;M)_n.
$$

Now, suppose that $A = \kappa[X]/(X^p)$ and let $a = \overline{X}$ be the class of X in A. Then, $(0 : a^n) = A$, for all $n \ge p$. Thus, $E(I)_n = 0$, for all $n \ge p + 1$. Moreover, for all $2 \leq n \leq p$, $(0 : a^n) = (a^{p-n})$ and $E(I)_n = (a^{p-n})/(a^{p-n+1})$, so $\text{rt}(I;M) = p$. Furthermore, $\psi_n(E(I;M)_{n+1}) = (a(a^{p-n-1}) + (a^{p-n+1}))/((a^{p-n+1}) = E(I;M)_n$. Thus, ψ_n is surjective and $E(\mathbf{G}(I;M))_n = 0$, for all $2 \le n \le p-1$. Thus, $\mathbf{st}(\mathbf{G}(I;M)) = 2$, whereas $\text{st}(I; P) = \text{rt}(I; M) = p$.

Example 3.2. (See [\[34,](#page-20-10) Example 5.1]) Let (A, \mathfrak{m}) be a noetherian local ring. Let a_1, a_2 a regular A-sequence and $p \geq 2$. Set $x_1 = a_1^p$ $_1^p, x_2 = a_2^p$ y^p_2 and $y = a_1 a_2^{p-1}$. Let *I* be the ideal generated by x_1, x_2, y . Then,

SD (I) = {1, 2, . . . , p} and st (I) = rt (I) = p.

Indeed, set $V = A[X_1, X_2, Y]$ and let $\varphi : V \to \mathbf{R}(I)$ be the presentation of $\mathbf{R}(I)$ sending X_i to x_i and Y to yt . A minimal generating set of the ideal ker(φ) is obtained from:

- a unique equation $F_n(X_1, X_2, Y) = a_1^{p-n} Y^n a_2^{p-n} X_1 X_2^{n-1}$ of degree n, for each n, $2 \leq n \leq p$;
- two equations $F_1(X_1, X_2; Y) = a_1^{p-1}Y a_2^{p-1}X_1$ and $G_1(X_1, X_2, Y) = a_2Y a_1X_2$ of degree 1.

Perturbing the ideal I in Example [3.2](#page-11-0) with an extra regular parameter a_3 and considering the ideal $J = (a_3)$ we get:

Example 3.3. (See [\[59,](#page-21-1) Example 6.1]) Let (A, \mathfrak{m}) be a 3-dimensional regular local ring, $\mathfrak{m} = (a_1, a_2, a_3)$. Let $p \geq 2, x_1 = a_1^p$ $_1^p, x_2 = a_2^p$ $a_2^p, y = a_1 a_2^{p-1} + a_3^p$ $_3^p$. Let *I* be the ideal generated by x_1, x_2, y and let J be the ideal generated by a_3 . Then,

$$
\mathbf{w}(J, A; I) = 2, \quad \mathbf{m}(J, A; I) = p, \quad \mathbf{s}(J, A; I) = p,
$$

$$
\mathbf{st}(I; A/J) = p, \quad \mathbf{rt}(I; A/J) = p.
$$

Since rad $(I) = \mathfrak{m}$, it follows that I is an \mathfrak{m} -primary ideal. Thus, grade $(I) = \text{ht}(I) = 3$. By [\[4,](#page-19-16) Corollary 1.6.19], x_1, x_2, y is a regular A-sequence. Thus, I is an ideal of linear type (see, e.g., [\[18\]](#page-19-1)). By Proposition [2.5,](#page-9-1) $E(I; A/J)_n = E(J, A; I)_n$, for all $n \geq 2$, so $$

Example [3.2](#page-11-0) says that $E(I; A/J)_m$ is generated by the coset $a_1^{p-m}Y^m - a_2^{p-m}X_1X_2^{m-1}$, for all $2 \leq m \leq p$. Moreover, $E(I; A/J)_n = 0$, for all $n \geq p+1$. By Proposition [2.2,](#page-7-1) we deduce that the class of $u_m := a_1^{p-m} y^m - a_2^{p-m} x_1 x_2^{m-1}$ spans $E(J, A; I)_m = I^m \cap J/I(I^{m-1} \cap J)$, for all $2 \le m \le p$. Furthermore, $E(J, A; I)_n = 0$, for all $n \ge p + 1$. Therefore, $\mathbf{m}(A, J; I) =$ st $(I; A/J) = p$ and $s (J, A; I) = rt (I; A/J) = p$.

Let us prove that $\mathbf{w}(J, A; I) = 2$. If we see that $I^m \cap J \subseteq I^{m-2}J$, for all $2 \le m \le p$, then, using the equalities in [\(2.2\)](#page-6-1), it follows that, for all $n \geq p+1$,

$$
I^{n} \cap J = I^{n-p}(I^{p} \cap J) \subseteq I^{n-p}(I^{p-2}J) = I^{n-2}J.
$$

So, let us prove that $I^m \cap J \subseteq I^{m-2}J$, for all $2 \le m \le p$. For such an m, we have

$$
I^m \cap J = u_m A + I(I^{m-1} \cap J).
$$

In particular, if $2 \leq m \leq p$,

$$
I^{m} \cap J = u_{m}A + I(I^{m-1} \cap J) = u_{m}A + u_{m-1}I + I^{2}(I^{m-2} \cap J)
$$

= $u_{m}A + u_{m-1}I + \dots + u_{3}I^{m-3} + I^{m-2}(I^{2} \cap J).$

Hence, it is enough to see that $u_m \in I^{m-2}J$, for all $2 \le m \le p$. A computation with SINGULAR [\[8\]](#page-19-17) says that

$$
u_m = a_1^{p-m} y^m - a_2^{p-m} x_1 x_2^{m-1} = \sum_{j=0}^{m-2} v_j (x_2^{m-2-j} y^j) a_3 \in (x_2, y)^{m-2} J, \text{ where}
$$

\n
$$
v_0 = a_1^{p-1} a_2^{p-m+1} a_3^{p-1}, \quad v_1 = a_1^{p-2} a_2^{p-m+2} a_3^{p-1}, \quad \dots, v_{m-3} = a_1^{p-m+2} a_2^{p-2} a_3^{p-1} \text{ and}
$$

\n
$$
v_{m-2} = (2a_1^{p-m+1} a_2^{p-1} a_3^{p-1} + a_1^{p-m} a_3^{2p-1}).
$$

Consider in Example [3.2](#page-11-0) an extra parameter a_3 and the ideal $J = (a_3)$, which is "normally transversal to I " (see [\[55,](#page-21-0) Definition 5.5.1 and Proposition 5.5.7]). We have:

Example 3.4. Let $A = \mathbb{k}[a_1, a_2, a_3]$ be the polynomial ring over a field k. Let $p \geq 2$, $x_1 = a_1^p$ $_1^p, x_2 = a_2^p$ $_2^p$, $y = a_1 a_2^{p-1}$. Let I be the ideal generated by x_1, x_2, y and let J be the ideal generated by a_3 . Then

$$
\mathbf{w}(J, A; I) = 1, \quad \mathbf{m}(J, A; I) = 1, \quad \mathbf{s}(J, A; I) = 1,
$$

$$
\mathbf{st}(I; A/J) = p, \quad \mathbf{rt}(I; A/J) = p.
$$

By Example [3.2,](#page-11-0) $\mathbf{st}(I; A/J) = \mathbf{rt}(I; A/J) = p$. Clearly, $I^n \cap J = I^n J = I(I^{n-1} \cap J)$, for all $n \geq 2$, so $E(J, A; I)_n = 0$ and $\mathbf{w}(J, A; I) = \mathbf{m}(J, A; I) = \mathbf{s}(J, A; I) = 1$.

Example 3.5. (See [\[34,](#page-20-10) Example 5.2]) Let (A, \mathfrak{m}) be a noetherian local ring. Let a_1, a_2 a regular A-sequence and let $p \geq 5$ be an odd integer. Set $x_1 = a_1^p$ $_1^p, x_2 = a_2^p \text{ and } y = a_1^2 a_2^{p-2}.$ Let I be the ideal generated by x_1, x_2, y . Then,

SD (I) = {1, 2, ...,
$$
(p-1)/2
$$
, $(p+1)/2$, p }, **st** (I) = $(p+3)/2$ and **rt** (I) = p .

Concretely, set $V = A[X_1, X_2, Y]$ and let $\varphi : V \to \mathbf{R}(I)$ be the presentation of $\mathbf{R}(I)$ sending X_i to x_it and Y to yt. A minimal generating set of equations of $R(I)$ is

- an equation $F_p(X_1, X_2, Y) = Y^p X_1^2 X_2^{p-2}$ of degree p;
- an equation $F_n(X_1, X_2, Y) = a_2 Y^n a_1 X_1 X_2^{n-1}$ of degree $n = (p+1)/2$;
- an equation $F_n(X_1, X_2, Y) = a_1^{p-2n} Y^n a_2^{p-2n} X_1 X_2^{n-1}$ of degree *n*, for each *n*, $2 \leq n \leq (p-1)/2;$

• two equations $F_1(X_1, X_2; Y) = a_1^{p-2}Y - a_2^{p-2}X_1$ and $G_1(X_1, X_2, Y) = a_2^2Y - a_1^2X_2$ of degree 1.

Perturbing the ideal I in Example [3.5](#page-12-0) with an extra regular parameter a_3 and considering the ideal $J = (a_3)$ we get:

Example 3.6. Let (A, \mathfrak{m}) be a 3-dimensional regular local ring, $\mathfrak{m} = (a_1, a_2, a_3)$. Let $p \geq 5$ be an odd integer, $x_1 = a_1^p$ $_1^p, x_2 = a_2^p$ $a_1^p, y = a_1^2 a_2^{p-2} + a_3^p$ $_3^p$. Let *I* be the ideal generated by x_1, x_2, y and let J be the ideal generated by a_3 . Then,

$$
\mathbf{w}(J, A; I) = 2, \quad \mathbf{m}(J, A; I) = (p+3)/2, \quad \mathbf{s}(J, A; I) = p,
$$

$$
\mathbf{st}(I; A/J) = (p+3)/2, \quad \mathbf{rt}(I; A/J) = p.
$$

The argument is similar to that of Example [3.3.](#page-11-1) Since I is an ideal of linear type, $\mathbf{m}(J, A; I) = \mathbf{st}(I; A/J)$ and $\mathbf{s}(J, A; I) = \mathbf{rt}(I; A/J)$. Example [3.5](#page-12-0) gives the value of st $(I; A/J)$ and rt $(I; A/J)$.

Now, consider in Example [3.5](#page-12-0) an extra parameter a_3 and the ideal $J = (a_3)$, which is normally transversal to I. Then, we get:

Example 3.7. Let $A = \mathbb{k}[a_1, a_2, a_3]$ be the polynomial ring over a field k. Let $p \geq 2$, $x_1 = a_1^p$ $_1^p, x_2 = a_2^p$ $_2^p$, $y = a_1^2 a_2^{p-2}$. Let *I* be the ideal generated by x_1, x_2, y and let *J* be the ideal generated by a_3 . Then,

$$
\mathbf{w}(J, A; I) = 1, \quad \mathbf{m}(J, A; I) = 1, \quad \mathbf{s}(J, A; I) = 1,
$$

$$
\mathbf{st}(I; A/J) = (p+3)/2, \quad \mathbf{rt}(I; A/J) = p.
$$

This follows from Example [3.5](#page-12-0) and the fact that for all $n \geq 1$, $I^n \cap J = I^n J$.

Remark 3.8. It would be interesting to find an example of a triple $(J, A; I)$ all of whose five invariants of Theorem [2.6](#page-9-0) were distinct.

The following easy lemma says where (not) to start when looking for such an example.

Lemma 3.9. *Let* J *be an ideal of* I*.*

- (1) If $\mathbf{w}(\mathit{J}, A; I) = 1$ and $\mathit{J} \subset I$, then $\mathbf{m}(\mathit{J}, A; I) = \mathbf{s}(\mathit{J}, A; I) = 1$.
- (2) *If* I *and* J *are normally transversal, then*

 $\mathbf{w} (J, A, I) = \mathbf{m} (J, A; I) = \mathbf{s} (J, A; I) = 1.$

(3) *If* $s(J, A; I) = 1$ *, then* $rt(I; A/J) \le rt(I)$ *and* $st(I; A/J) \le st(I)$ *.*

Proof. If $\mathbf{w}(\mathbf{J}, \mathbf{A}; \mathbf{I}) = 1$, then $\mathbf{I}^n \cap \mathbf{J} \subseteq \mathbf{I}^{n-1} \mathbf{J}$, for all $n \geq 1$. Since $\mathbf{J} \subset \mathbf{I}$, it follows that $I^n \cap J = I^{n-1}J$, for all $n \geq 2$. Therefore, for all $n \geq 2$,

$$
I^{n} \cap J = I^{n-1}J = I(I^{n-2}J) = I(I^{n-1} \cap J).
$$

Thus, $E(J, A; I)_n = 0$, for all $n \geq 2$ and $\mathbf{m}(J, A; I) = \mathbf{s}(J, A; I) = 1$. This proves (1). If *I* and *J* are normally transversal, then, for all $n \geq 2$, $I^n \cap J = I^nJ = I(I^{n-1} \cap J)$, so $E(J, A; I)_n = 0$ and $\mathbf{w}(J, A; I) = \mathbf{m}(J, A; I) = \mathbf{s}(J, A; I) = 1$, which proves (2). Finally, (3) follows from the rightmost inequality in (2.5) and Propositions [2.1](#page-6-0) and [2.4.](#page-9-2)

4. A Fibonacci-like set of sifted degrees

In the polynomial ring $A = \mathbb{K}[a_1, a_2]$ over a field k, consider an ideal I generated by 3 monomials of the same degree with no common factor. One can assume, without loss of generality, that I is generated by $x_1 = a_1^p$ $_1^p, x_2 = a_2^p$ $y = a_1^u a_2^{p-u}$ for two positive integers p and u such that $gcd(u, p) = 1$ and $u < p/2$.

Proposition 4.1. Let $A = \mathbb{K}[a_1, a_2]$ be the polynomial ring over a field \mathbb{K} . Let $p, u \in \mathbb{N}$, $p \ge 3, 1 \le u < p/2, \text{ and } \gcd(u, p) = 1. \text{ Let } x_1 = a_1^p$ $\binom{p}{1}, x_2 = a_2^p$ $a_2^p, y = a_1^u a_2^{p-u}.$ Let I be *the ideal generated by* $x_1 = a_1^p$ $x_1^p, x_2 = a_2^p \text{ and } y = a_1^u a_2^{p-u}.$ Let q_1, \ldots, q_{n-1} be the quotients *in Euclid's algorithm applied to* $r_0 := p$ *and* $r_1 := u$ *, i.e., for every* $1 \leq i \leq n-1$ *,* $r_{i-1} = q_i r_i + r_{i+1}$, with $q_i, r_{i+1} \in \mathbb{N}$, and $r_0 > r_1 \ldots > r_{n-1} > r_n = 0$. Then,

$$
SD (I) = \{d_{1,1}, \ldots, d_{1,q_1}\} \cup \{d_{2,1}, \ldots, d_{2,q_2}\} \cup \ldots \cup \{d_{n-1,1}, \ldots, d_{n-1,q_{n-1}}\},
$$
(4.1)

where each subset $\{d_{i,1}, \ldots, d_{i,q_i}\}$ *is a finite arithmetic progression with:*

- $d_{1,j} d_{1,j-1} = 1$ *and* $d_{1,1} = 1$;
- $d_{2,j} d_{2,j-1} = d_{1,q_1}$ *and* $d_{2,1} = d_{1,q_1} + 1;$

•
$$
d_{i,j} - d_{i,j-1} = d_{i-1,q_{i-1}}
$$
 and $d_{i,1} = d_{i-1,q_{i-1}} + d_{i-2,q_{i-2}}$, for every $3 \leq i \leq n-1$.

Moreover, $d_{n-1,q_{n-1}} = p$, so $\text{st}(I) = q_1 + \cdots + q_{n-1}$ and $\text{rt}(I) = p$.

Proof. Observe that $n \geq 2$ and, since $u < p/2$, $q_1 \geq 2$. Furthermore, $q_i \geq 1$, for every $2 \leq i \leq n-1$. A minimal generating set of the defining ideal of the Rees algebra of I is given in [\[5,](#page-19-15) Theorem 2.2]. In order to describe the degrees of these generators, i.e., the set SD (*I*) of sifted degrees of *I*, one has to focus on the sequence $(|\sigma_i - \tau_i|)$ introduced in [\[5\]](#page-19-15) and, in particular, use [\[5,](#page-19-15) Proposition 5.6] to check that for each sifted degree $\delta \geq 2$ of I there is exactly one equation of degree δ . A careful reading leads directly to the equality $(4.1).$ $(4.1).$

Now, let us prove that $d_{n-1,q_{n-1}} = p$. For all $1 \leq i \leq n-1$, let δ_{i+1} be the last element in the arithmetic sequence $\{d_{i,1}, \ldots, d_{i,q_i}\}$, i.e., $\delta_{i+1} = d_{i,q_i}$. Note that, for $2 \leq i \leq n-1$, $d_{i,q_i} = d_{i,1} + (q_i - 1)d_{i-1,q_{i-1}}$. On the other hand, $d_{i,1} = d_{i-1,q_{i-1}} + d_{i-2,q_{i-2}}$ if $i \geq 3$, and $d_{2,1} = d_{1,q_1+1}$. Thus, for all $2 \leq i \leq n-1$, one has that $d_{i,q_i} = d_{i-2,q_{i-2}} + q_i d_{i-1,q_{i-1}}$ if one sets $q_0 = 0$ and $d_{0,0} = 1$, i.e., $\delta_{i+1} = q_i \delta_i + \delta_{i-1}$. By setting $\delta_0 = 0$ and $\delta_1 = 1$, one has that this inductive relation also holds for $i = 1$, and the sequence $\{\delta_0, \ldots, \delta_n\}$ can also be defined recursively by

$$
\delta_0 = 0
$$
, $\delta_1 = 1$, and $\delta_{i+1} = q_i \delta_i + \delta_{i-1}$, for all $1 \le i \le n - 1$.

Similarly, one can define a sequence $\{\mu_0, \ldots, \mu_n\}$ by setting $\mu_0 = 1, \mu_1 = 0$, and considering the same inductive relation $\mu_{i+1} = q_i \mu_i + \mu_{i-1}$, for all $1 \leq i \leq n-1$. Note that the sequence $\{\delta_0, \ldots, \delta_n\}$ is completely determined by the quotients $\{q_1, \ldots, q_{n-1}\}$ of the Euclid's algorithm applied to $r_0 = p$ and $r_1 = u$. Moreover, since $\mu_2 = \mu_0 = 1$, the sequence $\{\mu_1, \ldots, \mu_n\}$ is exactly the δ -sequence associated to the shorter list of quotients ${q_2, \ldots, q_{n-1}}$, i.e., the sequence of quotients obtained from Euclid's algorithm applied to $r'_0 = u$ and $r'_1 = r_2$ that has, hence, one division less.

On the other hand, one can easily show by induction that, for all $0 \leq i \leq n$,

$$
\delta_i u - \mu_i p = (-1)^{i-1} r_i.
$$

For $i = n$, this gives the relation $\delta_n u = \mu_n p$.

Now, let us prove $\delta_n = p$ by induction on n. If $n = 2$, then, necessarily, $u = 1$, which corresponds to Example [3.2,](#page-11-0) so $SD(I) = \{1, 2, ..., p\}$ and, in particular, the largest integer in SD (I) is p. Applying the inductive hypothesis to the sequence $\{\mu_1, \ldots, \mu_n\}$, which corresponds to the Euclid's algorithm with $r'_0 = u$ and $r'_1 = r_2$, and which has one division less, we obtain $\mu_n = u$. Using the equality $\delta_n u = \mu_n p$, we deduce $\delta_n = p$.

From the description of SD (I) in [\(4.1\)](#page-14-2) and the equality $d_{n-1,q_{n-1}} = p$, we deduce that **st** (*I*) = $q_1 + \cdots + q_{n-1}$ and **rt** (*I*) = *p*. □

One can now play with possible quotients q_1, \ldots, q_{n-1} in Euclid's algorithm to obtain several interesting families.

Remark 4.2. Suppose that $u = 1$ in Proposition [4.7,](#page-17-0) which coincides with Example [3.2.](#page-11-0) Clearly, $u = 1$ is equivalent to $n = 2$. In this case, Euclid's algorithm has only one division, $r_0 = q_1r_1 + 0$, with $r_0 = p$, $r_1 = u = 1$ and $q_1 = p$. Hence, SD $(I) = \{1, 2, ..., p\}$ and $st (I) = rt (I) = p$, as said before in Example [3.2.](#page-11-0)

Remark 4.3. If $u \geq 2$ in Proposition [4.7,](#page-17-0) then Euclid's algorithm applied to $r_0 = p$ and $r_1 = u$ will have at least two divisions (i.e., $n \geq 3$). Suppose that $u = 2$. Assume that p is odd and $p \geq 5$, so that $1 \leq u < p/2$ and $gcd(u, p) = 1$. Euclid's algorithm applied to $r_0 = p$ and $r_1 = 2$ gives $r_0 = q_1r_1 + r_2$, for $q_1 = (p-1)/2$ and $r_2 = 1$; and $r_1 = q_2r_2$, for $q_2 = 2$. Thus, $n = 3$, there are two divisions and SD (*I*) is the union of two finite arithmetic progressions. Note that $d_{1,q_1} = q_1 = (p-1)/2$, $d_{2,1} = d_{1,q_1} + 1 = (p+1)/2$ and $d_{2,2} = d_{2,1} + d_{1,q_1} = p$. Therefore,

SD (I) = {1, 2, ...,
$$
(p-1)/2
$$
} \cup { $(p+1)/2, p$ }, **st** (I) = $(p+3)/2$ and **rt** (I) = p,

as already observed in Example [3.5.](#page-12-0)

Example 4.4. In Proposition [4.7](#page-17-0) take $p \ge 7$ odd and $u = (p-1)/2$. Note that $gcd(u, p) =$ 1 (otherwise, a common factor to u and p would also be a factor of $p - u = (p + 1)/2$ and this is impossible since $(p-1)/2$ and $(p+1)/2$ are consecutive integers). Thus, $1 \le u < p/2$ and $gcd(u, p) = 1$. Euclid's algorithm applied to $r_0 = p$ and $r_1 = (p - 1)/2$ gives $r_0 = q_1r_1 + r_2$, for $q_1 = 2$ and $r_2 = 1$; and $r_1 = q_2r_2$, for $q_2 = (p-1)/2$. So, $n = 3$, there are two divisions and $SD(I)$ is the union of two finite arithmetic progressions. Concretely,

SD (I) = {1,2}
$$
\cup
$$
 {2i + 1 | 1 \le i \le (p-1)/2}, **st** (I) = (p+3)/2 and **rt** (I) = p.

Observe that while $\mathbf{st}(I)$ and $\mathbf{rt}(I)$ coincide with those in Remark [4.3,](#page-16-0) SD (I) does not.

Example 4.5. In Proposition [4.7](#page-17-0) take $p \ge 8$, p a multiple of 4, and $u = (p-2)/2$. As in Example [4.4,](#page-16-1) if p and u had a common factor, it would also be a factor of $p - u =$ $(p+2)/2 = u + 2$, and hence it should be 2, which is impossible since u is odd. Thus, $1 \le u < p/2$ and $gcd(u, p) = 1$. Euclid's algorithm applied to $r_0 = p$ and $r_1 = (p - 2)/2$ gives $r_0 = q_1r_1 + r_2$, for $q_1 = 2$ and $r_2 = 2$; $r_1 = q_2r_2 + r_3$, for $q_2 = (p - 4)/4$ and $r_3 = 1$; and $r_2 = q_3r_3$, for $q_3 = 2$. So, $n = 4$, there are three divisions and SD (I) is the union of three finite arithmetic progressions. In fact,

$$
SD (I) = \{1, 2\} \cup \{2i + 1 \mid 1 \le i \le p/4\} \cup \{p\}, \quad \text{st} (I) = (p/4) + 3 \quad \text{and} \quad \text{rt} (I) = p.
$$

Note that $\mathbf{rt}(I) = 4(\mathbf{st}(I) - 3)$.

Example 4.6. In Proposition [4.7](#page-17-0) take $p = 8(2\ell + 1)$, for some $\ell \ge 1$, and $u = (p-4)/4$. Again, if p and u had a common factor, it would also be a factor of $4u$, and hence it would divide $p - 4u = 4$, and this is impossible because u is odd. Thus, $1 \le u \le p/2$ and $gcd(u, p) = 1$. Since $u = 4\ell + 1$, Euclid's algorithm applied to $r_0 = p$ and $r_1 = u$ gives $r_0 = q_1r_1 + r_2$, for $q_1 = 4$ and $r_2 = 4$; $r_1 = q_2r_2 + r_3$, for $q_2 = \ell$ and $r_3 = 1$; and $r_2 = q_3r_3$, for $q_3 = 4$. Thus, $n = 4$, there are three divisions and SD(I) is the union of three finite arithmetic progressions. One sees that:

$$
SD (I) = \{1, 2, 3, 4\} \cup \{4i + 1 \mid 1 \le i \le \ell\} \cup \{4\ell + 5, 8\ell + 6, 12\ell + 7, 16\ell + 8\},\
$$

and hence $\mathbf{st}(I) = \ell + 8$ and $\mathbf{rt}(I) = 16\ell + 8 = p$. Observe that $\mathbf{rt}(I) = 8(2\mathbf{st}(I) - 15)$.

Example 4.7. Let $(F_i)_{i\geq 0}$ be the Fibonacci sequence defined by $F_0 = 0$, $F_1 = 1$ and $F_{i+2} = F_{i+1} + F_i$, for all $i \geq 0$. Take in Proposition [4.7](#page-17-0) $p = F_{\ell+2}$ and $u = F_{\ell}$, for some $\ell \geq 4$. (The cases $\ell = 1, 2, 3$ have already been considered in the previous families.) Let *I* be generated by $x_1 = a_1^{F_{\ell+2}}$ $\frac{F_{\ell+2}}{1}$, $x_2 = a_2^{F_{\ell+2}}$ and $y = a_1^{F_{\ell}} a_2^{F_{\ell+1}}$ $2^{r_{\ell+1}}$. As $p - u = F_{\ell+1}$ and two consecutive terms in the Fibonacci sequence are relatively prime, one has that $1 \le u \le p/2$ and $gcd(u, p) = 1$. Applying Euclid's algorithm to $r_0 = F_{\ell+2}$ and $r_1 = F_{\ell}$ (recall that $u < p/2$, one has that $r_0 = q_1r_1 + r_2$, for $q_1 = 2$ and $r_2 = F_{\ell-1}$; $r_{i-1} = q_ir_i + r_{i+1}$, for $2 \leq i \leq \ell - 2$, with $q_i = 1$ and $r_{i+1} = F_{\ell-i}$; and $r_{\ell-2} = F_3 = 2 = q_{\ell-1}r_{\ell-1}$ with $q_{\ell-1} = 2$ and $r_{\ell-1} = F_2 = 1$. Thus, $n = \ell$, there are $\ell - 1$ divisions and SD (I) is the union of $\ell - 3$ singletons and two subsets of cardinality 2. One can check that

SD (I) = {
$$
F_2, F_3
$$
} \cup { F_4 } $\cup ... \cup$ { F_{ℓ} } \cup { $F_{\ell+1}, F_{\ell+2}$ },

and hence $\mathbf{st}(I) = \ell + 1$ and $\mathbf{rt}(I) = F_{\ell+2} = p$. Note that, for $\varphi = \frac{1+\sqrt{5}}{2}$ $\frac{1}{2}^{\sqrt{5}}$, one has:

$$
\mathbf{rt}(I) = F_{\mathbf{st}(I)+1} = \frac{\varphi^{\mathbf{st}(I)+1} - (-\varphi^{-1})^{\mathbf{st}(I)+1}}{\sqrt{5}}.
$$

Question 4.8. We would like to characterize the finite subsets $D \subseteq \mathbb{N}$ for which there exists an ideal I whose set of sifted degrees is $SD (I) = D$. In addition, given such a subset D, we would like to find an ideal I with $SD (I) = D$. For instance, given the Fibonacci-like set $D = \{1, 2, 3, 5, 8, 13, 21\}$, we have seen that $SD(x^{21}, y^{21}, x^8y^{13}) = D$ (see Example [4.7\)](#page-17-0).

5. More examples

We finish the present note with three more examples, now of a more theoretical nature. The first example is a strong and difficult result due to Simis, Ulrich and Vasconcelos, here re-stated using our "sifted type" terminology. To our knowledge, this theorem is one of the first results in the literature intended to provide a family of ideals with a large relation type, but with a few distinct degree equations. In that sense, it could be thought as a seed to the definition of sifted type.

Example 5.1. (See [\[46,](#page-21-6) Theorem 4.10]) Let A be a Gorenstein local ring with infinite residue field and let I be a strongly Cohen-Macaulay ideal of A of height $h \geq 2$ with minimal number of generators n, analytic spread ℓ and reduction number r. Assume that $\ell < n$ and that I satisfies \mathscr{F}_1 locally in codimension $n-2$ (see [\[18\]](#page-19-1) or [\[46\]](#page-21-6)). If $r \leq n-h$, then st $(I) = 2$ and $\text{rt}(I) = n - h + 1$.

The next example is again due to Simis, Ulrich and Vasconcelos. It serves as a counterexample to a Conjecture of Valla (see [\[15\]](#page-19-18)), by exhibiting a prime ideal generated by analytically independent elements, but not of linear type, nor syzygetic.

Example 5.2. (See [\[45,](#page-20-22) Proposition 4.5]) Let **p** be the homogeneous prime ideal of $A =$ $k[a_1, \ldots, a_9]$ generated by the polynomials:

$$
a_5a_7 + a_6a_9, a_3a_6a_8 + a_1a_4a_9, a_1a_4a_5 - a_3a_5a_8 + a_2a_6a_8 - a_1a_8a_9,
$$

$$
a_3a_5a_6 + a_2a_5a_7 + a_3a_5a_9 + a_1a_9^2, a_3a_6^2 + a_2a_6a_7 + a_3a_6a_9 - a_1a_7a_9,
$$

$$
a_3a_4a_6 + a_2a_4a_7 + a_3a_7a_8 + a_3a_4a_9.
$$

Then, $st(\mathfrak{p}) = rt(\mathfrak{p}) = 2$. There are eight linear equations for the Rees algebra, coming from the syzygy module of p, and one extra generador:

$$
a_1 a_3 X_1 X_2 + a_3 X_2 X_4 - a_2 X_2 X_5 + a_3 X_3 X_5 + a_1 a_2 X_1 X_6 - a_1 X_4 X_6.
$$

Finally, this last example, due to Hartshorne, gives an irreducible surface in \mathbb{C}^4 which is not a (set theoretically a) complete intersection.

Example 5.3. (See [\[14,](#page-19-19) Example 3.4.2] and [\[11,](#page-19-20) Example 3, p. 247]) Let V be the irreducible algebraic affine set $V = \{(s, st, t(t-1), t^2(t-1)) \in \mathbb{A}^4 \mid s, t \in k\}$, which is not a set-theoretically complete intersection. A run with SINGULAR says that $V = V(I)$, where I is the ideal defined by the elements:

$$
f_1 = x_1x_4 - x_2x_3
$$
, $f_2 = x_1^2x_3 + x_1x_2 - x_2^2$, $f_3 = x_3^3 + x_3x_4 - x_4^2$.

Then, $I = (f_1, f_2, f_3)$ is an ideal of linear type of $k[x_1, x_2, x_3, x_4]$. Moreover, $I(V) = \mathfrak{p}$, where **p** is the ideal defined by the polynomials f_1, f_2, f_3 and $f_4 = x_1x_3^2 + x_1x_4 - x_2x_4$. Then, **p** is a height 2 prime ideal of $k[x_1, x_2, x_3, x_4]$ with $st(\mathfrak{p}) = rt(\mathfrak{p}) = 2$. Observe that these calculations contradict the equality $I(V) = I$ stated in Geyer [\[11,](#page-19-20) p. 248].
