Abstract

Electromagnetic ion cyclotron (EMIC) waves are discrete electromagnetic emissions separated by multiple ion gyrofrequencies. Harmonic EMIC waves are defined as waves with a strong electric or magnetic field (or both) at the harmonics of the fundamental EMIC mode. In this paper, for the first time, we present a statistical study on harmonic EMIC waves by the Van Allen Probes. The EMIC waves are categorized into three types based on their harmonics: (1) fundamental mode only (without higher harmonics), (2) electrostatic (ES) harmonics, and (3) electromagnetic (EM) harmonics. Our statistical study shows that ES and EM harmonic EMIC waves predominantly occur on the dayside, outside the plasmasphere with $L > 5$ and are associated with a low f_{pe}/f_{ce} , a high proton β_H , and a strong fundamental EMIC mode. The results will advance our understanding of harmonic EMIC waves and their generation mechanisms.

Plain Language Summary

Electromagnetic ion cyclotron (EMIC) waves play an essential role in the acceleration and precipitation of charged particles in the Earth's magnetosphere. They can resonate with MeV electrons and keV ions in the Earth's magnetosphere and produce the rapid loss of radiation belt electrons and ring current ions. EMIC waves are sometimes accompanied by electrostatic or electromagnetic harmonic structures in their frequency spectrum, though the properties of these harmonics remain poorly understood. In this paper, we present the first statistical study of harmonic EMIC waves with a narrow-band fundamental mode, as observed by the Van Allen Probes. Based on their harmonic structures, we categorize the EMIC wave events into three types: fundamental mode only (without harmonics), electrostatic (ES) harmonics, and electromagnetic (EM) harmonics. Our statistical study shows that ES and EM harmonic EMIC waves mainly concentrate on the dayside outside the plasmasphere with $L > 5$ and are associated with a low f_{pe}/f_{ce} , a high proton β_H , and a strong fundamental mode. The statistical findings from these observations provide a foundation for further exploration of the mechanisms behind harmonic EMIC wave excitation.

1 Introduction

Electromagnetic ion cyclotron (EMIC) waves are electromagnetic emissions that occur within the Pc1-Pc2 geomagnetic pulsation frequency range, typically between 0.1 and 5 Hz (Allan & Poulter, 1992; Hartinger et al., 2022; Cornwall, 1965). They have been widely observed in the Earth magnetosphere (e.g., Anderson et al., 1990), solar wind (e.g., Jian et al., 2010), and other planets in the solar system (e.g., Barbosa, 1993; Boardsen et al., 2012). Typical EMIC waves propagate in a quasi-parallel direction and exhibit left-hand polarization below ion cyclotron frequencies. In the presence of heavy ions, such as helium (He⁺) and oxygen $(O⁺)$, magnetospheric EMIC waves can be divided into three bands: hydrogen, helium and oxygen bands, respectively (Koskinen & Kilpua, 2022). They can be excited by a pitch-angle anisotropy in energetic ions with energies of a few tens of keV (Gendrin et al., 1984; Jordanova et al., 2006), often caused by the injection of plasma sheet particles during geomagnetic storms (e.g., Chen et al., 2009, 2010), or by magnetospheric compression due to increased solar wind pressure or interplanetary shocks (e.g., Tsurutani et al., 2016; Yin et al., 2022; Usanova et al., 2010). EMIC waves preferentially occur in the afternoon sector near the magnetic equator (Allen et al., 2015) and on the dayside at large L-shells (Usanova et al., 2012). They become oblique along their propagation paths and undergo polarization reversal as the wave frequency crosses the crossover frequency at high latitudes (Fraser & Nguyen, 2001; Liu et al., 2013).

EMIC waves play a crucial role in the acceleration and precipitation of charged particles in the inner magnetosphere. They can resonate with relativistic (∼MeV) electrons through the gyroresonance, leading to the rapid loss of radiation belt electrons (e.g., Thorne & Kennel, 1971; Liu et al., 2012; Blum et al., 2015; Jordanova et al., 2008). Electrons with lower energies (tens to hundreds keV), can interact with EMIC waves via the bounce resonance, resulting in significant pitch angle scattering (Blum et al., 2019; Cao et al., 2017). In addition, EMIC waves can interact with ring current ions through gyroresonance and cause efficient ion precipitation (Jordanova et al., 2001, 2006). Recent studies have shown that EMIC waves can deplete radiation belt electrons and ring current ions simultaneously (e.g., Usanova et al., 2014; Lyu et al., 2022).

Recently, harmonic structures of EMIC waves have been reported. Zhu and Chen (2019) observed EMIC waves exhibiting strong electrostatic spectra at multiple and fractional frequencies of the fundamental EMIC waves. They proposed that these electrostatic harmonics are generated by wave-wave resonance between fundamental EMIC waves and an accompanying density mode, a density fluctuation caused by the compressional component of the wave's associated electric field. This mechanism was verified by using the cross-bicoherence of low-frequency EMIC waves, the density mode, and high-frequency EMIC waves. Moreover, Deng et al. (2022) observed harmonic EMIC waves with spectral peaks in both electric and magnetic fields, suggesting that higher-order harmonics are excited by wave-wave couplings between lower-order waves. They emphasized the key role of the second harmonic in this process, which has been supported by hybrid simulations and theoretical analysis (Xue et al., 2022; Yu et al., 2021).

Despite the case studies mentioned above, a comprehensive statistical analysis of harmonic EMIC waves remains lacking. In this paper, we utilize the Van Allen Probes data to conduct a statistical survey of harmonic EMIC waves characterized by the existence of electrostatic or electromagnetic harmonics and investigate their associated plasma conditions. Section 2 briefly introduces the Van Allen Probes data set and data methodology. The statistical results are presented in Section 3, followed by conclusions and discussions in Section 4.

2 Data Set and Methodology

We use data of the two Van Allen Probes from 2012 to 2019 to perform the statistical study. Magnetic field measurements are obtained from the Level-3 64 samples/s data in the Geocentric Solar Ecliptic (GSE) coordinate system, recorded by the fluxgate magnetometer sensor, part of the Electric and Magnetic Field Instrument Suite and Integrated Science (EMFISIS) suite (Kletzing et al., 2013). Electric field measurements are obtained from the Level-2 32 samples/s electric field data in the satellite's UVW coordinates, provided by the Electric Field and Waves (EFW) instrument (Wygant et al., 2013). The electric field measurement u and v components (in the spin plane) are used, and the w component along the spin axis is abandoned due to its high inaccuracy. We transform the magnetic fields into a field-aligned coordinate (FAC) system. The background magnetic field B_0 is calculated based on the time-averaged magnetic field data with a sliding window of 101 points, nearly 1.5 seconds. To calculate the electric and magnetic field spectra, we apply the fast Fourier transform (FFT) with a sliding window size of 1024-point time series and a 60-point overlap. The wave normal angles (WNAs) are determined through the singular value decomposition method (Santolík et al., 2003) based on the magnetic field.

Plasma density data are acquired from the Level-4 data, derived from the upper hybrid resonance frequency line identified from the electric field power spectrum by EM-FISIS (Kurth et al., 2015). The plasmapause is treated as a boundary layer with a finite width. Thus, the inner magnetosphere is divided into three regions: inside the plasmasphere, outside the plasmasphere, and at the plasmasphere boundary layer (PBL). The PBL is determined based on the criteria in Liu et al. (2020) and Gu et al. (2022). Their method ensures that the PBLs are associated with sharp density gradients and pronounced density drops over L-shell, and only one PBL exists in each inbound or outbound

Figure 1. Three types of EMIC waves with only fundamental waves, electromagnetic (EM) harmonics, and electrostatic (ES) harmonics. (a, h, o): Background plasma density (in black) and satellite relative position to the PBL (in red). (b, i, p): Wave electric field power spectrum density. (c, j, q): Wave magnetic field power spectrum density. (d, k, r): Wave electric (in blue) and magnetic (in red) field magnitude. (e, l, s): f_{pe}/f_{ce} (in blue) and background plasma proton β (in red). (f, m, t): Wave normal angle. (g, n, u): Ellipticity. The white solid and dashed lines in subfigures represent the gyrofrequency of proton f_{cH+} and helium ion f_{cHe+} , respectively.

orbit. Ion pitch-angle distributions are derived from the differential flux measured by the Helium, Oxygen, Proton, and Electron (HOPE) Mass Spectrometer (Funsten et al., 2013; Spence et al., 2013). The ion temperature in an arbitrary direction is calculated as $T =$ $\frac{1}{n}\int f_i(\mathbf{v})m_i v^2 d^3v$, where *n* represents number density and $f(\mathbf{v})$ is the phase space density in velocity space. The background plasma beta β is defined as the ratio of the plasma thermal pressure $(p = nk_BT)$ to the magnetic pressure $(p_{mag} = B^2/2\mu_0)$.

3 Results

We survey data from the Van Allen Probes throughout its mission (from 2012 to 2019) to identify EMIC wave events. We manually select events with narrow-band frequency, lasting at least five minutes, where the wave frequency remains nearly constant relative to the ion gyrofrequencies. These events are categorized into three types based on their harmonic properties: (1) fundamental-only (no higher harmonics), (2) electrostatic (ES) harmonics, and (3) electromagnetic (EM) harmonics. In this section, we first present three representative EMIC events observed by Van Allen Probe B (VAP-B), and then provide the statistical results based on the Van Allen Probes dataset.

Figure 1 shows examples of the three types of harmonic EMIC waves observed by Van Allen Probe (VAP-B). The left column (Fig 1a-1g) shows a fundamental harmonic EMIC wave event on September 22, 2015. Figure 1a shows the observed plasma density

(black) and relative relation to the PBL (red). The electric and magnetic field power spectral densities (PSDs) are presented in Figure 1b and 1c, respectively. A single narrowband EMIC wave is observed with frequency close to the helium ion gyrofrequency f_{cHe+} , occurred inside the plasmaphere. The bandwidth δf is less than 0.5 Hz, and the ratio of the bandwidth to the proton gyrofrequency $\delta f/f_{cH+}$ is smaller than 0.1. This type of EMIC wave is classified as a fundamental harmonic EMIC wave. In Figure 1d, we show the electric (blue) and magnetic (red) wave amplitudes. Figure 1e presents the ratio of the plasma frequency to the electron cyclotron frequency f_{pe}/f_{ce} with a value close to 10 (blue), and background proton beta β_H (red). They both slightly increase in this period. The WNAs are shown in Figure 1f, which indicates that these waves are nearly parallelly propagating. The wave polarization is primarily linear, as shown in Figure 1g. The middle column (Figure 1h-1n) show an ES harmonic EMIC wave event on November 16, 2012. The wave event is observed outside the plasmasphere during the VAP-B inbound pass at ∼ 18.2-18.7 UT (Figure 1h). Compared to the fundamental case (Figure 1b and 1c), besides the fundamental mode, the electric field PSDs in Figure 1j have the second and third harmonic emissions. Since the high harmonics have no corresponding magnetic fluctuation, we classify this type of EMIC waves as an ES harmonic EMIC wave. The electric amplitude (Figure 1k) of this ES harmonic event (around 2 mV/m) is much larger than that (Figure 1d) of the fundamental event (around 0.2 mV/m). The f_{pe}/f_{ce} of the ES harmonic EMIC wave event (around 2, Figure 1l) is much smaller than that of the fundamental event (around 10, Figure 1e). Similar to the fundamental case, Figure 1m and 1n show the WNAs and wave ellipticity. In Figure 1o-1u, we show an EM harmonic EMIC wave event observed on January 22, 2016, which occurred outside the plasmasphere. Compared with the electric and magnetic PSDs of the fundamental and ES harmonic events (Figure 1b $\&c, i.\&j)$, the second harmonic exists in the magnetic field. We name this type of EMIC event as electromagnetic (EM) harmonic EMIC waves. Compared with the fundamental case in Figure 1d, the electric and magnetic field amplitudes are both larger in the EM harmonic case (Figure 1r).

We perform a statistical study to address the statistical characteristics of these three types of EMIC waves. In total, we identify 72 fundamental EMIC wave events, 85 ES harmonic EMIC events, and 53 EM harmonic EMIC wave events. For each event, we record the time corresponding to the maximum electric field amplitude. The distribution of events across L-shell and magnetic local time (MLT) is shown in Figure 2, where the terms "In", "Out", and "At" indicate the locations inside the plasmasphere, outside the plasmasphere, and at the PBL, respectively, as mentioned in the section 2. Figure 2a shows that over 60% of the fundamental EMIC waves occur inside the plasmasphere (blue asterisks) or at the PBL region (black circles), with no explicit dependency on the MLT. In contrast, Figure 2b and 2c demonstrate that more than 80% ES harmonic EMIC waves and nearly 70% EM harmonic EMIC waves happen outside the plasmasphere, with nearly 90% ES harmonic EMIC waves and 85% EM harmonic EMIC waves occurring on the dayside.

In Figure 3, we present the dependencies of EMIC events on the position and background plasma conditions. The probability in each bin is computed as the ratio of the number of events in each bin to the total number of events for each type. Figure 3a-3l illustrate the probability distribution of events based on their positions, including MLT, magnetic latitude (Mlat), L-shell, and their relation to PBL location. Figure 3a-3c show that both EM and ES harmonic EMIC waves are more concentrated on the dayside, mainly at 9-15 MLT, compared to the fundamental EMIC waves. In Figure 3d-3f, we find that these three types of events are most frequently observed near the geomagnetic equator. This trend is consistent with the excitation of EMIC waves near the equator due to the injection of anisotropic energetic ring current ions (Chen et al., 2010; Jordanova et al., 2008). Consequently, their harmonics, when present, are also expected to be predominantly located in the same region. Notably, EM harmonic EMIC waves occur more frequently near the equator compared to ES harmonic EMIC waves. Figure 3g shows that

Figure 2. Event distributions across L-shell/MLT of: (a) Fundamental, (b) ES harmonic, and (c) EM harmonic EMIC events. The blue asterisks represent events inside the plasmasphere, the red triangles represent the events outside the plasmasphere, and the black circles represent the events at the PBL.

nearly 80% of fundamental EMIC events occur at $L < 5$, and 60% of these events take place inside the plasmasphere (Figure 3j). Conversely, more than 60% of ES and EM harmonic events are observed at $L > 5$ (Figure 3h,i), and over 70% occur outside the plasmasphere (Figure 3k,l). Figure 3m-o and 3p-r show the dependencies on f_{pe}/f_{ce} and proton beta β_H . Compared with the fundamental events, the harmonic cases tend to occur with smaller f_{pe}/f_{ce} (< 9) and larger proton β_H (> 0.1). The mean values of these parameters of the three types of harmonic EMIC waves are summarized in Table 1. It shows the fundamental events have smaller L∼4.5 and larger $f_{pe}/f_{ce} \sim 10$, while the harmonic events have larger L∼5 and smaller $f_{pe}/f_{ce} \sim 6$.

Figure 4 summarizes the event dependencies of wave properties. Panels a-c and df display the probability distributions of wave electric field amplitude E_w and magnetic field amplitude B_w , respectively. Note that, even though the wave electric and magnetic amplitudes of EMIC harmonics are considerably large, they are still several orders of magnitude smaller than those of the fundamental modes. Thus, The wave electric and magnetic amplitudes here are mainly contributed from the fundamental mode. More than 85% ES and EM events are observed with $E_w > 0.32$ mV/m and $B_w > 0.32$ nT, whereas nearly 70% fundamental events happen with $E_w < 0.32$ mV/m and $B_w < 0.32$ nT. This indicates that both ES and EM harmonic EMIC events are associated with a stronger elctromagnetic fundamental mode. Figure 4g-4i show the probability distributions of WNAs, revealing no significant differences in the WNA distributions among the three types of EMIC waves. In Table 1, the mean values of E_w and B_w support the conclusions drawn from the statistical results. Specifically, for ES harmonic events, E_w is nearly 10 times greater than that in the fundamental events, while B_w is nearly 2 times greater. For EM harmonic events, E_w is nearly 8 times greater, and B_w nearly 3 times greater compared to the fundamental events. The stronger fundamental mode in the harmonic event is aligned with previous studies (Zhu & Chen, 2019; Deng et al., 2022), indicating the nonlinear wave-wave excitation of the harmonic EMIC waves, which requires large amplitudes of fundamental waves.

4 Conclusions and Discussion

In this paper, we present, for the first time, a statistical study of the harmonic EMIC waves based on observations from the Van Allen Probes between 2012 and 2019. We focus on narrow-band EMIC waves, and categorize them into three groups based on the

Figure 3. Statistical results of the position and plasma conditions of three types of EMIC waves. (a-c) Magnetic Local Time (MLT);(d-e) Magnetic latitude (Mlat); (g-i) L-shell; (j-l) The relative position to the PBL; (m-o) f_{pe}/f_{ce} ; (p-r) Proton beta $\beta_H.$

Figure 4. Statistical results of the wave properties of the fundamental mode of the three types of EMIC waves: (a-c) Wave electric field amplitude, (d-f) Wave magnetic field magnitude, and (g-i) Wave normal angle.

presence of harmonics. We then compare the properties of these three types of EMIC waves. The main conclusions are summarized as follows:

(1) Harmonic EMIC waves are predominantly observed outside the dayside plasmasphere with $L > 5$.

(2) Harmonic EMIC waves tend to occur in regions with a low f_{pe}/f_{ce} (< 9) and a high proton β_H (> 0.1).

(3) Harmonic EMIC waves are mostly associated with strong fundamental modes $(E_w > 0.32 \text{ mV/m}$ and $B_w > 0.32 \text{ nT}$, indicating nonlinear processes in the harmonic excitation.

For now, the statistical differences in wave properties between ES and EM cases are not prominent. The underlying mechanisms responsible for these two types of harmonic EMIC waves remain controversial. Some works suggested that nonlinear wavewave coupling is responsible for exciting both two types of harmonic waves (e.g., Zhu & Chen, 2019; Deng et al., 2022). Sauer and Dubinin (2022) proposed that, in a multi-species plasma, energy and momentum exchange between different ion components could explain the origin of ES harmonic EMIC waves. Thus, identifying the distinct generation mechanisms behind these two types of waves will be the focus of our future work.

EMIC waves play a vital role in scattering electrons in the radiation belt, with previous studies primarily focusing on the interaction between electrons and monochromatic EMIC waves. An et al. (2014) proposed a two-wave model, showing that interactions with two-wave EMIC waves can induce more stochastic scattering of MeV electrons compared to single-wave interactions, as demonstrated through theory and test-particle simulations. In the future, we plan to investigate the response of electrons to harmonic EMIC waves, and compare this with their response to monochromatic EMIC waves based on observations.

This study confirms the existence of narrow-band intense EMIC waves. The higher harmonic components, when present, are significantly weaker than the fundamental component, but may still influence the saturation of the fundamental wave amplitude. Future research, using particle-in-cell simulations, will aim to explore the underlying nonlinear physics involved in these processes.

Open Research Section

The data of Van Allen Probes used in this paper are provided by the Space Physics Data Facility (SPDF) (https://spdf.gsfc.nasa.gov/pub/data/rbsp/). The EMIC wave event list used in this paper is in the dataset (?, ?).
