Abstract—Code-switching (CS) automatic speech recognition (ASR) faces challenges due to the language confusion resulting from accents, auditory similarity, and seamless language switches. Adaptation on the pre-trained multi-lingual model has shown promising performance for CS-ASR. In this paper, we adapt Whisper, which is a large-scale multilingual pre-trained speech recognition model, to CS from both encoder and decoder parts. First, we propose an encoder refiner to enhance the encoder’s capacity of intra-sentence switching. Second, we propose using two sets of language-aware adapters with different language prompt embeddings to achieve language-specific decoding information in each decoder layer. Then, a fusion module is added to fuse the language-aware decoding. The experimental results using the SEAME dataset show that, compared with the baseline model, the proposed approach achieves a relative MER reduction of 4.1% and 7.2% on the dev_man and dev_sge test sets, respectively, surpassing state-of-the-art methods. Through experiments, we found that the proposed method significantly improves the performance on non-native language in CS speech, indicating that our approach enables Whisper to better distinguish between the two languages.

Index Terms—speech recognition, code-switching, encoding refining, adaptation

I. INTRODUCTION

The rapid development of model pre-training significantly benefits automatic speech recognition (ASR) [1]–[5]. How to more effectively utilize pre-trained models to obtain better recognition performance attracts more and more attention [6], [7]. There are two main methods for ASR pre-training: self-supervised learning (SSL) [8]–[12] and weak-supervision training [2]. SSL uses massive unlabeled data to pre-train the model. Such a pre-trained model cannot directly perform ASR [1], [13], [14]. Thus, finetuning on labelled datasets is necessary. On the other hand, weak-supervision training designs rules to obtain and filter a large amount of speech-transcription data, which is used to train the neural network directly. In this way, the weak-supervision training-based model can directly perform ASR [2].

Pre-training data can involve monolingual [16] and multilingual speech [8]. Some studies suggest that training on multilingual data often leads to higher performance [1]. Multilingual speech is also referred to as inter-sentence code-

switching (CS). Code-switching (CS) refers to the switching of languages within a speech signal [17]. While inter-sentence code-switching data are widely used for pre-training, intra-sentence code-switching speech, which also commonly appears in multilingual communities, is rarely considered. Due to the seamless transition between languages and the scarcity of paired data, CS poses significant challenges to ASR systems [18], [19], even for those with multilingual capabilities. Adapting large pre-trained multilingual speech models to the CS ASR task is thus crucial [20], [21].

Enabling the model to better capture language switches within the utterance better is one of the effective ways to improve CS ASR [22]–[25]. This can be achieved from both the encoder and decoder. By updating the parameters of the additional LID-guided and CTC-guided modules, the frame-level language identity (LID) embedded in fixed Wav2Vec 2.0 [26] is combined with Connectionist Temporal Classification (CTC) to enable the joint CTC-LID framework to handle the CS [27]. In contrast to the abundance of multilingual speech data, intra-sentence code-switching data is relatively scarce. As a result, adaptation with adapter modules generally exhibits comparable or even higher performance than conducting full fine-tuning on the pre-trained model for CS-ASR. [22] leverages Massively Multilingual Speech (MMS) to handle CS by incorporating language-specific adapters after encoder layers. Although inserting the adapters into the encoder makes it acquire CS capabilities, the adapter’s simple structure may limit the encoding capabilities, especially for capturing the boundary of language switching [28].

Decoder’s adaptation is often performed on Whisper [2], which is a weakly-supervised pre-trained model for ASR and speech translation. In addition to using the adapter, the design of the input prompt has also shown its efficacy on Whisper performance [30], [31]. When prompts consisting of concatenated or weighted token embeddings from two languages are fed into the Whisper decoder, CS performance outperforms those with default prompts. However, concatenated or weighted language prompt embeddings perform poorly in zero-shot scenarios, while similar performance is observed regardless of the language prompt used during fine-tuning [31]. Therefore, further research on prompts in the adaptation process is necessary. Enabling Whisper to acquire better capabilities in capturing

All experiments, including all work done with the SEAME dataset, are conducted at Tianjin University and Nanyang Technological University

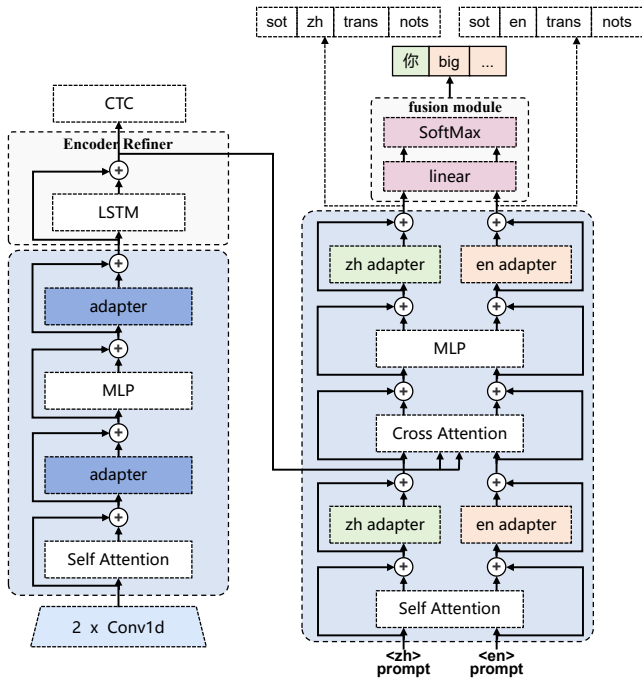

Fig. 1: The encoder refiner and the language-aware adaptation of the proposed method.

language-switching is a primary challenge in its adaptation to the CS-ASR task.

In this paper, we adapt the Whisper for CS-ASR from both the encoder and decoder modules. Compared with monolingual speech, CS speech is more complex, which makes the adapter needs to capture intra-sentence switching instead of only the domain mismatches. However, the simple adapter structure makes it hard to provide such capabilities [29]. Thus, we first propose an encoding refiner, which uses a structure with stronger temporal modeling, to help the encoder obtain better CS capabilities. An additional CTC layer is used during training to guide the encoder refiner in learning better language-switching encoding. After obtaining an encoder more suitable for CS, the decoder is also designed to adapt much more efficiently. Different language prompts exhibit complementary characteristics in decoding [30], [31]. We thus propose language-aware decoding to investigate how to use prompts more efficiently. Two sets of adapters with different language prompts are inserted into each decoder layer to capture language-specific decoding information. A fusion module is used to fuse the two language-specific decoding embeddings after the decoder.

II. PRELIMINARIES

A. Adapter

Adapter is a type of additive parameter-efficient finetuning method that involves adding domain-specific layers between neural network modules. In low-resource conditions, by adjusting only the parameters of the adapters, performance comparable to full finetuning can be achieved [32]. In the field of NLP, adapters are utilized for additive parameter-efficient

finetuning of large pre-trained models. LoRA, as a type of adapter, is typically a fully-connected network with a hidden dimension smaller than the input. The adaptation process of LoRA is depicted as follows:

$$e' = e + \text{Adapter}(e) \quad (1)$$

Here, e represents the input embedding. e' represents the adapted embedding.

B. Low-Resource Language Adaptation

Large-scale pre-trained multilingual ASR models have been reported to be advantageous in low-resource languages. Despite their excellent capabilities, these models require finetuning on target-domain data to adapt to downstream tasks [33], [34]. Finetuning large models mainly faces three challenges: being computationally and time-consuming, overfitting, and catastrophic forgetting [33]. Among many finetuning strategies, adapter-based adaptation offers the dual advantage of avoiding catastrophic forgetting and reducing training time [35]. Adapters are usually added after the attention and FFN in each Transformer encoder and decoder layer:

$$\begin{aligned} h' &= \text{SelfAtt}(h) + \text{Adapter}(\text{SelfAtt}(h)), \\ h'' &= \text{MLP}(h') + \text{Adapter}(\text{MLP}(h')), \end{aligned} \quad (2)$$

where h is the input feature or embedding from the last module of one layer. h' and h'' represent the adapted embedding of the self-attention mechanism and the MLP layer.

C. Whisper

Whisper [2] is a large-scale weakly supervised pre-trained multilingual ASR model, adopting a transformer-based encoder-decoder architecture. Many studies on the domain adaptation of Whisper for low-resource languages ASR have already been conducted. Song *et al.* [36] assign a language-specific LoRA matrix for each language, enabling the model to efficiently adapt to specific languages. Huang *et al.* [35] integrate adapters into the Whisper model and explore their effectiveness in addressing the issue of catastrophic forgetting. Aditya *et al.* [28] employ concatenated language prompts and finetunes Whisper by incorporating adapters. An attention-guided Language Identification (LID) loss is introduced to enhance the decoder's ability to distinguish between the two languages. Peng *et al.* [30] and Yang *et al.* [31] modify Whisper prompts to adapt to CS ASR, demonstrating that $\langle |en| \rangle$ prompt performs better on the English-dominant test set, while $\langle |zh| \rangle$ prompt performs better on the Mandarin-dominant test set.

III. PROPOSED METHOD

Fig. 1 illustrates the overall structure of our method, which consists of Encoding Refining and Language-aware Decoding. Previous works [22] show that enabling the model to better capture language switches within utterances is crucial. Thus, in this paper, we propose an encoder refiner to enhance the encoder's capacity of intra-sentence switching. Additionally, we propose language-aware decoding to enable Whisper's decoder to better distinguish between the two languages.

A. Encoding Refining

To do the adaptation, adapters are added after each encoder layer’s self-attention and the MLP to learn language switches without catastrophic forgetting. We propose an encoder refiner to improve the encoding capability of the Whisper encoder for ASR. It consists of several LSTM layers and a CTC. The LSTM layers have temporal modeling capability, refining the encoder’s output to capture more effective encoded embeddings. CTC is used to train the encoder refiner to better learn language switches. The refining process of the encoder refiner is as follows:

$$\mathbf{h}'_{enc} = \text{LSTM}(\mathbf{h}_{enc}), \quad (3)$$

where \mathbf{h}_{enc} is the last hidden states output of the encoder. \mathbf{h}'_{enc} is the refined encoding. The training loss of the encoder refiner is as follows:

$$\mathcal{L}_{CTC} = \text{CTC}(\hat{\mathbf{y}}, \mathbf{h}'_{enc}). \quad (4)$$

LSTM is supervised by CTC loss, as equation, where $\hat{\mathbf{y}}$ represents the text tokens. During the finetuning, the overall training loss is defined as:

$$\mathcal{L}_{enc_ref} = \alpha * \mathcal{L}_{att} + (1 - \alpha) * \mathcal{L}_{CTC}. \quad (5)$$

where \mathcal{L}_{att} denotes the attention-based decoder loss, and \mathcal{L}_{CTC} represents the CTC loss. The hyperparameter α controls the relative contribution of each loss component to the final training loss function.

B. Language-aware Decoding

To make the decoder better distinguish between the two languages, the language-aware adapters are inserted after both the self-attention and MLP of each decoder layer. The shared self-attention processes two language-aware embeddings:

$$\mathbf{h}_{dec_zh} = \text{Adapter}_{zh1}(\text{SelfAtt}(\mathbf{p}_{zh}, \hat{\mathbf{y}}_{1:t-1})), \quad (6)$$

$$\mathbf{h}_{dec_en} = \text{Adapter}_{en1}(\text{SelfAtt}(\mathbf{p}_{en}, \hat{\mathbf{y}}_{1:t-1})),$$

where \mathbf{p}_{zh} , \mathbf{p}_{en} are the language-specific prompt embeddings. Then, the shared frozen cross-attention processes two language-aware embeddings:

$$\mathbf{h}'_{dec_zh} = \text{CrossAtt}(\mathbf{h}_{dec_zh}, \mathbf{h}'_{enc}), \quad (7)$$

$$\mathbf{h}'_{dec_en} = \text{CrossAtt}(\mathbf{h}_{dec_en}, \mathbf{h}'_{enc}),$$

where \mathbf{h}'_{enc} represents the output of the encoder refiner. Finally, the two embeddings are adapted with different adapters:

$$\mathbf{h}''_{dec_zh} = \text{Adapter}_{zh2}(\text{MLP}(\mathbf{h}'_{dec_zh})), \quad (8)$$

$$\mathbf{h}''_{dec_en} = \text{Adapter}_{en2}(\text{MLP}(\mathbf{h}'_{dec_en})),$$

Using the language-specific adapters, which are guided by different language prompts, enables the decoder to be aware of the corresponding language during the attention-based decoding.

At the end of the decoder, we add a lightweight fusion module. The fusion module uses two linear layers to estimate the weights for two language-specific embeddings:

$$\begin{aligned} \text{weights}'_{zh} &= \text{Softmax}(\text{Linear}_{zh}(\mathbf{y}_{dec_zh})), \\ \text{weights}'_{en} &= \text{Softmax}(\text{Linear}_{en}(\mathbf{y}_{dec_en})), \end{aligned} \quad (9)$$

where \mathbf{y}_{dec_zh} , \mathbf{y}_{dec_en} represents the extracted language-specific embedding of the last decoder layer. The weights $\text{weights}'_{zh}$ and $\text{weights}'_{en}$ are estimated for fusion:

$$\mathbf{y}'_{mix} = \text{weights}'_{zh} * \mathbf{y}_{dec_zh} + \text{weights}'_{en} * \mathbf{y}_{dec_en}, \quad (10)$$

where \mathbf{y}'_{mix} represents the final fused output of decoder. The training loss for language-aware decoding is computed as follows:

$$\mathcal{L}_{dec} = \mathcal{L}_{att} + \text{CE}(\mathbf{h}''_{dec_zh}, \mathbf{p}_{zh}) + \text{CE}(\mathbf{h}''_{dec_en}, \mathbf{p}_{en}). \quad (11)$$

The proposed encoding refining and language-aware decoding can be used simultaneously. The training loss of it is as follows:

$$\mathcal{L}_{final} = \lambda * \mathcal{L}_{dec} + (1 - \lambda) * \mathcal{L}_{CTC}. \quad (12)$$

λ is a hyperparameter to balance the two losses.

IV. EXPERIMENTS

A. Experimental Settings

Our experimental data is the SEAME Mandarin-English Code-Switch dataset [37], which contains spontaneous conversational speech. Both intra- and inter-sentence CS speech exist in this dataset. The training set has a duration of 101.13 hours and includes 134 speakers; one of the test sets, led by Mandarin, has a duration of 7.49 hours and includes 10 speakers; one of the test sets, led by Singaporean English, has a duration of 3.93 hours and includes 10 speakers. Performances are measured by character error rate (CER) for Mandarin, word error rate (WER) for English, and the total mix error rate (MER) for the code-switching scenarios.

We evaluated the performance of our proposed method on Whisper-small. Whisper-small has 12 heads and 12 transformer layers in encoder and decoder. Hidden dimension of adapters was 192. The encoder refining module was utilized with two LSTM layers. The hidden dimension size of LSTM was 512. We used Adam optimizer with learning rate 1×10^{-4} . In the training stage, the model was trained for 8 epochs. The evaluation model was selected from the best step based on the validation loss. We set α and λ to 0.7 and 1.0, respectively.

B. Experimental Results and Analysis

Table I shows the overall performance of encoding refining and language-aware decoding for CS ASR. The baselines include the pre-trained Whisper-small (ID-0) and adapter-based adaptation methods (ID-1 to ID-4). The decoding language prompts of the pre-trained Whisper-small (ID-0) for the dev_man and dev_sge test sets were $\langle |en| \rangle$ and $\langle |zh| \rangle$, respectively. Its poor performance suggests that handling CS directly using the pre-trained Whisper is challenging. With adapter-based adaptation, the CS performance significantly improved. The language prompt of all the adapter-based baselines was the concatenation of $\langle |en| \rangle$ and $\langle |zh| \rangle$. Only encoder (ID-1) or decoder (ID-2) adaptation and both encoder and decoder adaptation (ID-3) were evaluated. Experimental results show that the efficacy of adaptation on the encoder was better than that on the decoder. Moreover, the adaptation of both encoder

Our Propose	✓	✗	-	14.0	20.6

and decoder further improved performance. We also used CTC to improve the encoder misalignment problem further (ID-4). However, this degraded the model performance.

1) *Performance of Encoding Refining*: The result of encoding refining is shown in Table I (ID-5). Its language prompt was also the concatenation of $\langle |en| \rangle$ and $\langle |zh| \rangle$. Compared with the best result in baselines (ID-3), the encoder refiner (ID-5 and ID-6) significantly improved the performance. Most interesting is that the encoder refining improved the performance of non-native speaker regions, especially training with CTC (ID-6): the relative improvement was about 5% for EN in Dev_man subset; while the relative improvement was about 20% in ZH in Dev_sge subset. ID-4 and ID-6 all trained with CTC. The encoder refiner allows the model to learn more information from CTC using a more complex neural network structure instead of only the LoRA adapter.

2) *Performance of Language-aware Decoding*: The proposed language-aware decoding uses two sets of adapters for processing different language information. Experimental results (ID-7) showed that the proposed language-aware decoding also improved the performance of non-native speaker regions: the relative improvement was about 4% for EN in

Dev_man subset; while the relative improvement was about 22% in ZH in Dev_sge subset. Using the proposed encoder refiner and language-aware decoding simultaneously further improved performance (ID-8). Overall, the proposed method (ID-8) had about 4.1% and 7.2% relatively improvement on the Dev_man, and Dev_sge sets over the baseline model (ID-3), respectively.

3) *Comparison with other Outstanding Methods*: Table II compares different CS ASR models on the SEAME dataset in the literature. Those well-performing models that were trained from scratch and adapted based on the pre-trained models were all used for comparison. Models trained from scratch are not zero-shot on CS. Thus, they had good CS ability, especially on the Dev_man set. Among these methods, aligning different language parts was effective, especially after adding a speech model (“LAL” and “LAL + hypo. corr.”). The pre-trained models are often zero-shot. Although some content can be recognized when evaluating CS directly on these pre-trained models, the performance is relatively poor. Using CS data to adapt the models significantly improved the pre-trained model performance. AG Whisper [28] represents the previous state-of-the-art model before our proposed method.

V. CONCLUSIONS

In this work, we propose an encoder refiner for the Whisper encoder and perform language-aware adaptation on the Whisper decoder. The encoder refiner can adopt various structures, and we demonstrated its effectiveness through experiments with LSTM and CTC architectures. Experimental results show that the encoder refiner achieves a 2.1% and 6.3% relative MER reduction on dev_man and dev_sge test sets compared to the baseline model by enhancing the encoder’s capability to encode CS speech. Additionally, in language-aware decoding, the two sets of adapters within each decoder layer extract language-specific information under different language prompts. Experimental results show that language-aware decoding achieves a 3.4% and 6.8% relative MER reduction on dev_man and dev_sge test sets compared to the baseline model. This demonstrates that the two points we proposed for adapting Whisper are effective, and the final model achieves a 4.1% and 7.2% relative MER reduction on dev_man and dev_sge test sets compared to the baseline model.
