#### **Abstract**

In this paper we continue the development of a new technique for computing elimination ideals by substitution which has been called *Z*-separating re-embeddings. Given an ideal *I* in the polynomial ring  $K[x_1, \ldots, x_n]$  over a field *K*, this method searches for tuples  $Z = (z_1, \ldots, z_s)$  of indeterminates with the property that *I* contains polynomials of the form  $f_i = z_i - h_i$  for  $i = 1, \ldots, s$ such that no term in  $h_i$  is divisible by an indeterminate in  $Z$ . As there are frequently many candidate tuples  $Z$ , the task addressed by this paper is to efficiently check whether a given tuple *Z* has this property. We construct fast algorithms which check whether the vector space spanned by the generators of  $I$  or a somewhat enlarged vector space contain the desired polynomials *fi*. We also extend these algorithms to Boolean polynomials and apply them to cryptoanalyse round reduced versions of the AES cryptosystem faster.

### **1 Introduction**

Computing elimination ideals has long been one of the key tasks of computer algebra. In algebraic geometry, they define projections of varieties or schemes, in linear algebra

and number theory, they are applied to find minimal polynomials, and in numerous applications, they are used to help solve polynomial systems of equations. Traditionally, elimination ideals have been computed using resultants or using Gröbner bases with respect to elimination term orderings. As these techniques become impractical when the number of indeterminates is large, a new technique, called *Z*-separating reembeddings, and based on trying to perform elimination by substitution, has been developed in [\[12](#page-27-0)[–14,](#page-27-1) [17\]](#page-27-2). This technique proceeds as follows.

Let  $P = K[x_1, \ldots, x_n]$  be a polynomial ring over a field K, and let I be an ideal in *P*. Given a tuple of distinct indeterminates  $Z = (z_1, \ldots, z_s)$  in  $X = (x_1, \ldots, x_n)$ , we say that a tuple of polynomials  $(f_1, \ldots, f_s)$  in *I* is *Z*-separating if there exists a term ordering  $\sigma$  such that  $LT_{\sigma}(f_i) = z_i$  for  $i = 1, ..., s$ . If we find such a tuple of polynomials, we can calculate a tuple of *coherently Z-separating polynomials* and then the elimination ideal  $I \cap K[X \setminus Z]$  by potentially less costly interreductions and substitutions. Notice that in contrast to [\[12–](#page-27-0)[14\]](#page-27-1) we do not assume  $I \subseteq \langle x_1, \ldots, x_n \rangle$ here, as this hypothesis is not needed for our algorithms to work.

Fast methods for determining good candidate tuples *Z* for which a *Z*-separating tuple of polynomials might exist in *I* were developed in [\[13,](#page-27-3) [14,](#page-27-1) [17\]](#page-27-2). Here we study the second phase of the method, namely to determine quickly whether the ideal *I* contains a *Z*-separating tuple of polynomials for a given *Z*. To answer this question in full generality, one would have to compute a Gröbner basis of  $I$ , the very task that we deem infeasible and want to avoid. Hence we will content ourselves with an algorithm which checks very quickly if the vector space spanned by the given generators of *I*, or a somewhat larger, easily calculated vector space, contains a *Z*-separating tuple. These algorithms are fast enough to allow us to scan many hundred candidate tuples *Z* in a matter of seconds, and are therefore suitable for applications involving larger polynomial systems. For instance, in the final section we apply them to speed up algebraic attacks on the AES-128 cryptosystem.

Now let us describe the contents of the paper in more detail. In Section [2](#page-2-0) we recall the basic definitions of separating and coherently separating tuples of polynomials, and of separating re-embeddings. Then, in Section [3,](#page-4-0) we introduce the main algorithm of this paper (see Algorithm [3.2\)](#page-6-0). It allows us to discover very efficiently when a given polynomial ideal contains a *Z*-separating tuple. However, it is allowed to fail in certain complicated cases. The idea of this algorithm is to construct a weight vector  $W \in \mathbb{N}^n$  such that, for every term ordering  $\sigma$  which is compatible with the grading on *P* given by *W*, there exists a *Z*-separating tuple of polynomials  $(f_1, \ldots, f_s)$  in *I* with  $LT_{\sigma}(f_i) = z_i$  for  $i = 1, ..., s$ . Moreover, in Proposition [3.3,](#page-7-0) we prove that this algorithm succeeds exactly when the vector space spanned by the initially given system of generators of *I* contains a *Z*-separating tuple.

Section [4](#page-11-0) introduces an optimization of our main algorithm. Algorithm [4.1](#page-11-1) allows us to find *Z*-separating tuples of polynomials in *I* in more cases than Algorithm [3.2](#page-6-0) at the cost of a small reduction in efficiency. The underlying idea is derived from the border basis algorithm (see [\[11\]](#page-27-4)). We do not search for a *Z*-separating tuple in the vector space  $V$  spanned by the original generators of  $I$ , but in the larger vector space  $V^+ = V + x_1 V + \cdots + x_n V$ . The loss in efficiency is mostly due to the necessity to perform some linear algebra operations (see Remark [4.3\)](#page-14-0).

Now assume that one of these algorithms confirms the existence of a *Z*-separating tuple in *I*. It still remains to find an actual such tuple. This task is tackled in Section [5.](#page-14-1) In case the existence has been shown by Algorithm [3.2,](#page-6-0) a straightforward base change mechanism allows us to exhibit an actual *Z*-separating tuple of poylnomials in *I* (see Algorithm [5.1\)](#page-14-2). If the existence has been shown using Algorithm [4.1,](#page-11-1) the situation is a bit trickier: in this case we have to mimick some linear algebra operations performed by the algorithm on simplified polynomials using the original generators instead (see Remark [5.3\)](#page-15-0). We also explain how to pass from a *Z*-separating tuple to a coherently *Z*-separating tuple (see Remark [5.4\)](#page-16-0).

If we want to apply these algorithms in situations involving Boolean polynomials, it suffices to adjust them slightly. In Section [6](#page-17-0) we first provide the necessary background knowledge about canonical representatives, Boolean Gröbner bases, Zseparating and coherently *Z*-separating tuples of Boolean polynomials, as well as Boolean *Z*-separating re-embeddings. Based on the result that the canonical representatives of a tuple of Boolean polynomials are *Z*-separating if and only if the tuple itself is *Z*-separating (see Proposition [6.3\)](#page-19-0), we show how to find *Z*-separating tuples of Boolean polynomials (see Proposition [6.4\)](#page-19-1).

Finally, in Section [7,](#page-21-0) we apply the algorithms in order to improve algebraic attacks on the cryptosystem AES-128. These improvements are a consequence of better algebraic representations of the S-boxes of this cipher (see Example [7.1\)](#page-21-1). They translate to more compact representations of *r*-round AES-128 in several logic normal forms such as CNF, CNF-XOR or XNF. For one round of AES-128, these better representations translate to meaningful speed-ups of state-of-the-art Boolean solvers (see Example [7.3\)](#page-23-0), and for two rounds of AES, we get faster solutions in the case when we know some key bits (see Example [7.4\)](#page-24-0).

All algorithms are illustrated by non-trival explicit examples. These examples were calculated using implementations of the algorithms in the computer algebra systems ApCoCoA(see [\[20\]](#page-27-5)), CoCoA(see [\[1\]](#page-26-0)), and SageMath (see [\[21\]](#page-27-6)). The source code is available upon request from the authors. The general notation and definitions in this paper follow [\[15,](#page-27-7) [16\]](#page-27-8).

### <span id="page-2-0"></span>**2 Separating Tuples and Separating Re-Embeddings**

In the following we let *K* be an arbitrary field, let  $P = K[x_1, \ldots, x_n]$ , let *I* be a proper ideal in *P*, and let  $R = P/I$ . Rings of this form are also called *affine K*-*algebras*, since they are the affine coordinate rings of closed subschemes of  $\mathbb{A}^n_K$ . The well-known task of re-embedding those subschemes into lower dimensional affine spaces can be phrased in terms of their coordinate rings as follows (see [\[12\]](#page-27-0), [\[13\]](#page-27-3)).

**Definition 2.1.** Let  $R = P/I$  be an affine *K*-algebra.

- (a) A *K*-algebra isomorphism  $\Phi: R \longrightarrow P'/I'$ , where *P'* is a polynomial ring over *K* and  $I'$  is an ideal in  $P'$ , is called a **re-embedding** of  $I$ .
- (b) A re-embedding  $\Phi$  :  $R \longrightarrow P'/I'$  of *I* is called **optimal**, if every *K*-algebra isomorphism  $R \longrightarrow P''/I''$  with a polynomial ring  $P''$  over  $K$  and an ideal  $I''$ in  $P''$  satisfies  $\dim(P'') \geq \dim(P')$ .

In a series of papers ([\[12\]](#page-27-0), [\[13\]](#page-27-3), [\[14\]](#page-27-1)) methods were developed for finding good re-embeddings using the following technique. Let  $X = (x_1, \ldots, x_n)$ , and let  $Z =$  $(z_1, \ldots, z_s)$  be a tuple of pairwise distinct indeterminates in X.

<span id="page-3-0"></span>**Definition 2.2.** Let *I* be a proper ideal in *P*.

- (a) The tuple  $Z$  is called a **separating tuple of indeterminates** for  $I$ , if there exists a term ordering  $\sigma$  and a tuple of polynomials  $F = (f_1, \ldots, f_s)$  with  $f_i \in I$  such that  $LT_{\sigma}(f_i) = z_i$  for  $i = 1, \ldots, s$ .
- (b) In this case we say that *F* is a *Z***-separating tuple** in *I*.
- (c) If, additionally, we have  $f_i = z_i h_i$  with  $h_i \in K[X \setminus Z]$  for  $i = 1, \ldots, s$ , then *F* is called a **coherently** *Z***-separating tuple** in *I*.

Notice that, in contrast to [\[12\]](#page-27-0), [\[13\]](#page-27-3), and [\[14\]](#page-27-1), we do not require  $I \subseteq \mathfrak{M} =$  $\langle x_1, \ldots, x_n \rangle$  here. Also note that the condition  $LT_{\sigma}(f_i) = z_i$  in this definition implies that no other term in  $\text{Supp}(f_i)$  is divisible by  $z_i$ . When we consider the subideal  $J = \langle f_1, \ldots, f_s \rangle$  of *I*, the tuple *F* is a minimal monic *σ*-Gröbner basis for *J*. After interreducing the polynomials in  $F$ , we obtain the reduced  $\sigma$ -Gröbner basis  $\widetilde{F} = (\widetilde{f}_1, \ldots, \widetilde{f}_s)$  of *J*, which is then a coherently *Z*-separating tuple.

Given a coherently *Z*-separating tuple in *I*, we can define a re-embedding of *I* as in the following proposition (cf. [\[12\]](#page-27-0), [\[13\]](#page-27-3)). Here we denote by  $\text{Lin}_{\mathfrak{M}}(I)$  the ideal  $\langle \text{Lin}(f) | f \in I \rangle$ , where  $\text{Lin}(f)$  denotes the *linear part* of a polynomial  $f \in I$ , i.e., its homogeneous component of degree 1. Note that if *I* contains a polynomial with a nonzero constant term, then  $\lim_{M} (I) = \langle x_1, \dots, x_n \rangle_K$ . If *I* is contained in M then the ideal Lin<sub>90</sub>(*I*) is generated by the linear parts of a system of generators of *I* (see [\[12\]](#page-27-0), Prop. 1.9).

#### **Proposition 2.3. (***Z***-Separating Re-Embeddings)**

Let *Z* be a tuple of distinct indeterminate in *X*, let  $Y = X \setminus Z$ , let *I* be a proper ideal *in P*, and let  $\widetilde{F} = (\widetilde{f}_1, \ldots, \widetilde{f}_s)$  *be a coherently Z-separating tuple of polynomials in I. For*  $i = 1, \ldots, s$ *, write*  $\tilde{f}_i = z_i - \tilde{h}_i$  with  $\tilde{h}_i \in P$ .

*(a) The K*-algebra homomorphism  $\varphi : P \longrightarrow K[Y]$  *defined by*  $z_i \mapsto \tilde{h}_i$  *for*  $i = 1, \ldots, s$  $and \varphi(x_i) = x_i$  *for*  $x_i \notin Z$  *induces a K*-*algebra isomorphism* 

$$
\Phi: P/I \longrightarrow K[Y]/(I \cap K[Y])
$$

*which is called a Z***-separating re-embedding** *of I.*

*(b) Suppose that*  $I \subseteq \mathfrak{M} = \langle x_1, \ldots, x_s \rangle$  *and*  $s = \dim_K(\text{Lin}_{\mathfrak{M}}(I))$ *. Then we have* edim( $P/I$ ) =  $n - s$ , *i.e.*, the *Z*-separating re-embedding of *I is an optimal re-embedding.*

In view of this proposition, the task of finding good, or even optimal, re-embeddings of a polynomial ideal can be divided into two steps:

(1) Find candidate tuples  $Z$  such that the ideal  $I$  has a reasonable chance of containing a *Z*-separating tuple of polynomials.

(2) Given a candidate tuple *Z*, check whether *I* does indeed contain a *Z*-separating tuple.

To perform the first step, for instance the following approaches have been proposed.

<span id="page-4-2"></span>**Remark 2.4.** Let *I* be a proper ideal in *P*. Suppose we want to find a tuple *Z* of distinct indeteminates in *X* which is a separating tuple for *I*.

(a) If we can find a term ordering  $\sigma$  such that  $Z \subseteq LT_{\sigma}(I)$  then *Z* is a separating tuple of indeterminates for *I*. For instance, we can take all indeterminates contained in  $LT_{\sigma}(I)$ .

Unfortunately, checking all leading term ideals  $LT_{\sigma}(I)$  involves the computation of the Gröbner fan of *I*. This is known to be an extremely hard computation in general, as the Gröbner fan tends to contain many elements. One improvement can be to compute a *restricted Gröbner fan* (see [\[13\]](#page-27-3)).

(b) If the ideal *I* is contained in  $\mathfrak{M} = \langle x_1, \ldots, x_n \rangle$ , it turns out that it is sufficient to compute the Gröbner fan of the linear part  $\text{Lin}_{\mathfrak{M}}(I)$  of *I* (see [\[14\]](#page-27-1), Prop. 2.6). This task can be reduced to finding the minors of a matrix (see [\[14\]](#page-27-1), Thm. 3.5 and Alg. 4.1). In general, this may still be quite demanding, but for instance when  $\text{Lin}_{\mathfrak{M}}(I)$  is a binomial linear ideal, it can be simplified further (see [\[14\]](#page-27-1), Alg. 5.7).

In view of this remark we concentrate in the following on step (2) of the above procedure. In other words, we assume that we are given a tuple *Z* of indeterminates and want to check whether it is separating for *I*. Even if an ideal contains a *Z*-separating tuple of indeterminates, this may not be apparent by looking at its generators (see for instance [\[14\]](#page-27-1), Example 2.4). In general, checking whether a given tuple *Z* of indeterminates is a separating tuple of indeterminates for *I* may require us to compute a Gröbner basis and thus be infeasible for large examples.

### <span id="page-4-0"></span>**3 Checking Separating Tuples of Indeterminates**

As before, we let *I* be a proper ideal in  $P = K[x_1, \ldots, x_n]$ , we let  $X = (x_1, \ldots, x_n)$ , and we let  $Z = (z_1, \ldots, z_s)$  be a tuple of distinct indeterminates in X. Our goal in this section is to find fast methods for determining whether *Z* is a separating tuple of indeterminates for *I*, i.e., whether *I* contains a *Z*-separating tuple of polynomials. Since the calculation of a Gröbner basis of  $I$  with respect to an elimination term ordering for *Z* is, in general, too expensive, we construct procedures which are allowed to fail. We start by introducing the following algorithm, which is a part of Algorithm [3.2,](#page-6-0) the main algorithm of this paper.

#### <span id="page-4-1"></span>**Algorithm 3.1. (Linear Interreduction)**

Let  $Z = (z_1, \ldots, z_s)$  be a tuple of distinct indeterminates in X, and let  $\sigma$  be *the lexicographic term ordering on P. Moreover, let*  $g_1, \ldots, g_r \in P$  *such that*  $\dim_K(\langle \text{Lin}(g_1), \ldots, \text{Lin}(g_r) \rangle_K) = s$  and such that every term in the union of the sup*ports of*  $g_1, \ldots, g_r$  *is divisible by at least one of the indeterminates in Z. Consider the following sequence of instructions.*

- *1: Compute*  $T = (z_1, \ldots, z_s, t_1, \ldots, t_m)$  *where*  $\{t_1, \ldots, t_m\}$  *is the combined support of*  $g_1, \ldots, g_r$  *without*  $z_1, \ldots, z_s$ *, ordered such that*  $t_1 > \sigma \cdots > \sigma t_m$ *.*
- 2: Form the coefficient matrix  $M \in Mat_{r,m+s}(K)$  of  $g_1, \ldots, g_r$  with respect to the *terms in T.*
- 3: *Compute the matrix*  $N \in Mat_{r',r}(K)$  *such that*  $N \cdot M \in Mat_{r',m+s}(K)$  *is in reduced row echelon form and has no zero rows.*
- 4: *Compute*  $(g'_1, \ldots, g'_{r'})^{\text{tr}} = N \cdot (g_1, \ldots, g_r)^{\text{tr}}$  and return  $g'_1, \ldots, g'_{r'}$ .

*This is an algorithm which computes a <i>K-basis*  $g'_1, \ldots, g'_{r'}$  of  $\langle g_1, \ldots, g_r \rangle_K$  such *that the following conditions hold.*

- (a) For  $i = 1, ..., s$ , the polynomial  $g'_i$  is of the form  $g'_i = z_i h_i$ , where  $h_i \in P_{\geq 2}$ .
- *(b)* Let  $u = r' s$ *. For*  $j = 1, \ldots, u$ *, we get*  $g'_{s+j} = q_j \in P_{\geq 2}$  *such that the polynomials*  $q_1, \ldots, q_u$  *have distinct leading terms with respect to*  $\sigma$ .
- *(c) The polynomials*  $q_1, \ldots, q_u$  *form a K*-basis of  $\langle q_1, \ldots, q_r \rangle_K \cap P_{\geq 2}$ .
- *(d)* For every  $i \in \{1, \ldots, s\}$ , we have  $z_i \in \langle g_1, \ldots, g_r \rangle_K$  if and only if  $g'_i = z_i$ .

*Proof.* Let  $U = \langle g_1, \ldots, g_r \rangle_K$ . First observe that  $N \cdot M$  is the coefficient matrix of  $g'_1, \ldots, g'_{r'}$  with respect to the terms in *T*. Since the rows of  $N \cdot M$  form a *K*-basis of the row space of *M*, the polynomials  $g'_1, \ldots, g'_{r'}$  form a *K*-basis of *U* by the isomorphism between the row space of *M* and *U*.

To prove (a), we first note that  $1 \notin \{t_1, \ldots, t_m\}$  since 1 is not divisible by any indeterminate in *Z*. Let  $V = \langle \text{Lin}(g_1), \ldots, \text{Lin}(g_r) \rangle_K$ . Since  $\dim_K(V) = s$  and every term in the combined support is divisible by an indeterminate from  $Z$ , we have  $V =$  $\langle Z \rangle_K$ . This shows that the upper left *s* × *s* submatrix of *N* · *M* is the identity matrix and hence  $\text{Lin}(g_i') = z_i$  for  $i = 1, ..., s$  and we can write  $g_i' = z_i - h_i$  where  $h_i \in P_{\geq 2}$ since  $1 \notin \text{Supp}(h_i)$ .

To prove (b), we note that  $\text{Lin}(g'_{s+j}) = 0$  and  $1 \notin \text{Supp}(g'_{s+j})$  for  $j = 1, ..., u$ . This yields  $g'_{s+j} \in P_{\geq 2}$ . The remaining claim follows from the observations that the coefficient matrix  $N \cdot M$  of  $g'_1, \ldots, g'_{r'}$  is in reduced row-echelon form and that the terms  $t_1, \ldots, t_m$  are sorted decreasingly with respect to  $\sigma$ .

For the proof of (c), let  $q \in U \cap P_{\geq 2}$ . By (a), there exist  $a_1, \ldots, a_s, b_1, \ldots, b_u \in K$ such that  $q = a_1(z_1 - h_1) + \cdots + a_s(z_s - h_s) + b_1q_1 + \cdots + b_uq_u$ . Then  $0 = \text{Lin}(q)$  $a_1z_1 + \cdots + a_sz_s$  implies  $a_1 = \cdots = a_s = 0$ . Hence we get  $q \in \langle q_1, \ldots, q_u \rangle_K$ . This shows  $\langle q_1, \ldots, q_u \rangle_K = U \cap P_{\geq 2}$ . By (b), the polynomials  $q_1, \ldots, q_u$  are *K*-linearly independent, and therefore a *K*-basis of  $U \cap P_{\geq 2}$ .

Finally, we show (d). Let  $i \in \{1, ..., s\}$  such that  $z_i \in U$ . Since  $g'_i \in U$ , we get *h*<sub>i</sub> = *z*<sub>i</sub> − *g*<sup>'</sup><sub>i</sub> ∈ *U* ∩ *P*≥2. Then (c) yields  $h_i \in \langle q_1, \ldots, q_u \rangle_K$ . Since  $N \cdot M$  is in reduced row echelon form, the leading terms of  $q_1, \ldots, q_u$  do not appear in the support of  $h_i$ . However, since these polynomials have distinct leading terms according to (b), every nonzero element  $q \in \langle q_1, \ldots, q_u \rangle_K$  satisfies  $LT_{\sigma}(q) = LT_{\sigma}(q_i)$  for some *j*. This shows  $h_i = 0$ , and hence  $g'_i = z_i$ . For the other implication, note that if  $g'_i = z_i$ , then clearly  $z_i = g'_i \in U$ .  $\Box$ 

Now we are ready to introduce the main algorithm of this paper. Its basic idea is to try to find a tuple of weights  $W = (w_1, \ldots, w_n)$  for the indeterminates in X such that for every term ordering  $\sigma$  compatible with the grading given by *W* there exist polynomials  $f_i \in I$  with  $LT_{\sigma}(f_i) = z_i$  for  $i = 1, \ldots, s$ .

#### <span id="page-6-0"></span>**Algorithm 3.2. (Checking Separating Indeterminates)**

*Let*  $g_1, \ldots, g_r \in P$ , let  $I = \langle g_1, \ldots, g_r \rangle$ , and let  $Z = (z_1, \ldots, z_s)$  be a tuple of distinct *indeterminates in X. Consider the following sequence of instructions.*

- *1: Set*  $w_i = 0$  *for*  $i \in \{1, ..., n\}$ *,*  $\delta = \max\{\deg(g_1), ..., \deg(g_r)\}\$ *, and*  $d = 1$ *.*
- 2: Delete in  $g_1, \ldots, g_r$  every monomial which is not divisible by an indeterminate *in Z and call the result*  $g_1, \ldots, g_r$  *again.*
- *3: if* dim<sub>*K*</sub>( $\langle \text{Lin}(g_1), \ldots, \text{Lin}(g_r) \rangle_K$ )  $\lt \#Z$  *then*
- *4: return "Fail".*
- *5: end if*
- *6: repeat*
- *7: Apply Algorithm [3.1](#page-4-1) to*  $g_1, \ldots, g_r$  *and Z and call the result*  $g_1, \ldots, g_r$  *again.*
- *8:*  $Set \, \overline{Z} = Z \cap \{g_1, \ldots, g_r\}.$ <br>*q*  $if \, \widetilde{Z} = \emptyset \, then$
- 
- $\begin{array}{ll} g_{\mathbb{C}} & \textit{if $\widetilde{Z} = \emptyset$ then} \ & \textit{if $\widetilde{Z} = \emptyset$ then} \ & \textit{return ``Fe} \end{array}$ *10: return "Fail".*
- *11: end if*
- *12: for all*  $z_i \in \widetilde{Z}$  *do*<br>*13: Let*  $k \in \{1, \ldots, n\}$
- *Let*  $k \in \{1, \ldots, n\}$  *with*  $x_k = z_i$  *and set*  $w_k = d$ *.*
- $14:$  *Remove*  $z_i$  from  $Z$ .
- *15: end for*
- *16: Delete in g*1*, . . . , g<sup>r</sup> every monomial which is not divisible by an indeterminate in Z and call the result*  $g_1, \ldots, g_r$  *again.*
- *17:*  $\qquad$  *Replace*  $d$  *by*  $\delta \cdot d + 1$ *.*
- *18: until Z is empty.*
- *19:*  $return W = (w_1, \ldots, w_n).$

*This is an algorithm which returns either "Fail" or a tuple of non-negative weights*  $W = (w_1, \ldots, w_n) \in \mathbb{N}^n$ . If it returns a tuple *W*, then there are  $f_1, \ldots, f_s \in$  $\langle g_1, \ldots, g_r \rangle_K$  *such that*  $(f_1, \ldots, f_s)$  *is a Z-separating tuple of polynomials for I, and such that every term ordering*  $\sigma$  *which is compatible with the grading given by W satisfies*  $LT_{\sigma}(f_i) = z_i$  *for*  $i = 1, \ldots, s$ *.* 

*Proof.* For the finiteness of the algorithm, it suffices to verify that the loop in Steps [6-](#page-6-0) [18](#page-6-0) terminates. In every iteration of the loop, the algorithm either stops in Step [10](#page-6-0) or the number of elements in *Z* decreases in Step [14.](#page-6-0) This yields that the loop terminates after finitely many iterations.

Now suppose that we are at the start of an iteration of the loop in Steps [6-18.](#page-6-0) Let *U* be the *K*-vector space generated by the input polynomials and let *T* be the set of all terms deleted in Step [2](#page-6-0) or in an execution of Step [16](#page-6-0) in a previous iteration of the loop. We show that the following properties hold at the start of every iteration of the loop.

(1) The polynomials  $g_1, \ldots, g_r$  are a valid input for Algorithm [3.1,](#page-4-1) i.e.,

(1.1) every term in the support of  $g_1, \ldots, g_r$  is divisible by an indeterminate from Z,  $(1.2) \dim_K(\langle \text{Lin}(g_1), \ldots, \text{Lin}(g_r) \rangle_K) = \#Z.$ 

- (2) We have  $g_1, \ldots, g_r \in U + \langle T \rangle_K$ .
- (3) All terms in *T* have  $(w_1, \ldots, w_n)$ -weight smaller than *d*.

To prove  $(1.1)$ , we note that every monomial not divisible by an indeterminate from *Z* was either deleted in Step [2](#page-6-0) or in Step [16](#page-6-0) in an earlier iteration of the loop, so the claim holds.

Next we show (1.2). In the first iteration, passing the condition in Steps [3-](#page-6-0) [5](#page-6-0) guarantees the claim. Assume that it holds at the start of an iteration of the loop that is not the last iteration. Then, after Step [7,](#page-6-0) Algorithm [3.1.](#page-4-1)a yields  $h_1, \ldots, h_s, q_1, \ldots, q_r \in P_{\geq 2}$  such that  $(g_1, \ldots, g_r) = (z_1 - h_1, \ldots, z_s - h_s, q_1, \ldots, q_r)$ . Without loss of generality assume that  $\tilde{Z} = \{z_1, \ldots, z_k\}$  for  $k < s$ . Then, after the execution of Step [16](#page-6-0) and therefore at the start of the next loop, we have  $(g_1, \ldots, g_r)$  $(0,\ldots,0,z_{k+1}-\tilde{h}_{k+1},\ldots,z_s-\tilde{h}_s,\tilde{q}_1,\ldots,\tilde{q}_r)$  where  $\tilde{h}_{k+1},\ldots,\tilde{h}_s,\tilde{q}_1,\ldots,\tilde{q}_r\in P_{\geq 2}$ . Consequently,  $\langle \text{Lin}(g_1), \ldots, \text{Lin}(g_r) \rangle_K = \langle z_{k+1}, \ldots, z_s \rangle_K$  has dimension  $s - k = \#Z$ .

To show (2), we observe that it holds after the execution of Step [2,](#page-6-0) and thus at the start of the first iteration of the loop. Moreover, the property is preserved by *K*-linear interreductions and monomial deletions, which are the only operations performed on  $g_1, \ldots, g_r$  during the loop in Steps [6-18.](#page-6-0) This implies (2).

To prove (3), notice first that, if a term *t* is added to *T* at any point of the algorithm, then every later execution of Step [13](#page-6-0) only changes the weight of an indeterminate in *Z* which does not divide *t*. Hence the weight of *t* does not change anymore. Moreover, if  $t \in T$  is deleted in Step [2,](#page-6-0) then its weight is 0 which is smaller than  $d = 1$ . If it is deleted in Step [16,](#page-6-0) then every indeterminate dividing *t* has weight 0 or has been assigned a weight smaller than or equal to *d*. Hence  $\deg(t) \leq \delta$  implies that the weight of *t* is smaller or equal to  $\delta \cdot d < \delta \cdot d + 1$ . This shows that, at the start of the next iteration of the loop, the weight of *t* is smaller than *d*.

Now assume that the algorithm successfully returned a weight tuple *W*. Then claim (2) yields that, for every  $z_i \in Z$ , there was an iteration of the loop in Steps [6-18](#page-6-0) where we had  $z_i \in U + \langle T \rangle_K$  in Step [8.](#page-6-0) Thus we can write  $z_i = f_i + p_i$ , where  $f_i \in U$ and  $p_i \in \langle T \rangle_K$ . By claim (3), every term in *T* has *W*-weight smaller than *d*, while  $z_i$ has *W*-weight *d*. Hence every term ordering  $\sigma$  compatible with the grading given by *W* satisfies  $LT_{\sigma}(f_i) = LT_{\sigma}(z_i - p_i) = z_i$ . Notice that  $f_i \in U = \langle g_1, \ldots, g_r \rangle_K$ .  $\Box$ 

The next proposition characterizes when Algorithm [3.2](#page-6-0) is successful.

<span id="page-7-0"></span>**Proposition 3.3.** Let  $g_1, \ldots, g_r \in P$ , let  $I = \langle g_1, \ldots, g_r \rangle$ , and let  $Z = (z_1, \ldots, z_s)$  be *a tuple of distinct indeterminates in X. Then the following conditions are equivalent.*

- *(a) Algorithm [3.2](#page-6-0) successfully computes a weight tuple W.*
- (b) There exists a  $Z$ -separating tuple  $(f_1, \ldots, f_s)$  of polynomials in I such that  $f_1, \ldots, f_s \in \langle q_1, \ldots, q_r \rangle_K$ .

*Proof.* The correctness of Algorithm [3.2](#page-6-0) shows that (a) implies (b). Thus we only need to show that (b) implies (a). Assume that there are  $f_1, \ldots, f_s \in \langle g_1, \ldots, g_r \rangle_K$  such that  $(f_1, \ldots, f_s)$  is a *Z*-separating tuple of polynomials in *I*. Let  $\tau$  be a term ordering on *P* such that  $LT_{\tau}(f_i) = z_i$  for  $i = 1, \ldots, s$ .

First we show that the algorithm does not terminate in Step [4.](#page-6-0) For this, let  $f'_1, \ldots, f'_s$  be the result of deleting in  $f_1, \ldots, f_s$  every term which is not divisible by an indeterminate from *Z*. Similarly, for  $i = 1, ..., r$ , let  $g'_i$  be obtained from  $g_i$  in the same way. Then  $f'_1, \ldots, f'_s \in \langle g'_1, \ldots, g'_r \rangle_K$ . This shows  $\text{Lin}(f'_1), \ldots, \text{Lin}(f'_s) \in$ 

 $\langle \text{Lin}(g_1), \ldots, \text{Lin}(g_r) \rangle_K$ . Here  $\text{Lin}(f'_1), \ldots, \text{Lin}(f'_s)$  are *K*-linearly independent, since  $LT_{\tau}(f_i') = z_i$  yields  $LT_{\tau}(\text{Lin}(f_i')) = z_i$  for  $i = 1, ..., s$ . Hence the condition in Step [3](#page-6-0) is false.

It remains to show that the algorithm does not fail in Step [10.](#page-6-0) For this, let  $\hat{g}_1, \ldots, \hat{g}_{\hat{r}}$ be the original input polynomials of the algorithm, let  $U = \langle \hat{g}_1, \ldots, \hat{g}_r \rangle_K$ , and write  $\widehat{S} = \bigcup_{i=1}^{r} \text{Supp}(\hat{g}_i)$ . At any state of the algorithm, let  $U = \langle g_1, \ldots, g_r \rangle$ , let  $S =$  $\bigcup_{i=1}^r \text{Supp}(g_i)$ , let  $T = \widehat{S} \setminus S$  be the set of deleted terms, and let  $\varphi : \langle S \rangle_K \to \langle S \rangle_K$ be the map representing the deletions, i.e., the *K*-linear map defined by  $\varphi(t) = t$  for  $t \in S$  and  $\varphi(t) = 0$  for  $t \in T$ .

Let us show that  $U = \varphi(\widehat{U})$  at every step of the algorithm. First notice that after the execution of Step [3,](#page-6-0) we have  $r = \hat{r}$  and  $g_i = \varphi(\hat{g}_i)$  for  $i = 1, \ldots, r$ , so  $U = \langle g_1, \ldots, g_r \rangle_K = \langle \varphi(\hat{g}_1), \ldots, \varphi(\hat{g}_r) \rangle_K = \varphi(\hat{U})$ . This still holds at the start of the first iteration of the loop in Steps [6-18.](#page-6-0) Since *U* is invariant under Step [7](#page-6-0) in view of Algorithm [3.1,](#page-4-1) it is only left to show that the claim still holds after the execution of Step [16.](#page-6-0) For this, assume that we are after an execution of Step 16. Write  $S$ ,  $\bar{\varphi}$ , and *U* for the values of *S*,  $\varphi$ , and *U* before the execution of Step [16,](#page-6-0) respectively. Write  $\psi$ :  $\langle \overline{S} \rangle_K \to \langle S \rangle_K$  for the map representing the term deletion in this single execution of Step [16,](#page-6-0) i.e., the *K*-linear map with  $\psi(t) = t$  for  $t \in S$  and  $\psi(t) = 0$  for  $t \in \overline{S} \setminus S$ . Then  $\varphi = \psi \circ \bar{\varphi}$  and  $U = \psi(\bar{U}) = \psi(\bar{\varphi}(\hat{U})) = \varphi(\hat{U})$ . Therefore  $U = \varphi(\hat{U})$  holds after the execution of Step [16,](#page-6-0) and hence at the start of the next iteration of the loop.

Now we show that  $\widetilde{Z} \neq \emptyset$  in every execution of Step [8.](#page-6-0) Assume that we are at the start of an iteration of the loop in Steps [6-18](#page-6-0) and let  $z_i \in Z$  be the minimal element of *Z* with respect to *τ*. Write  $f_i = az_i + p_i$  with  $a \in K \setminus \{0\}$  and  $p_i \in P$  such that  $az_i$ is the leading monomial of *f<sup>i</sup>* . Then none of the indeterminates in *Z* divides any of the terms in  $p_i$ , since any term divisible by an element of  $Z$  is larger than or equal to  $z_i$ with respect to  $\tau$ . This shows  $\text{Supp}(p_i) \cap S = \emptyset$ , which in turn implies  $\varphi(p_i) = 0$ , and hence  $z_i = \varphi(f_i) \in \varphi(\hat{U}) = U = \langle g_1, \ldots, g_r \rangle_K$ . Finally, looking at Algorithm [3.1.](#page-4-1)d, we note that after the execution of Step [7](#page-6-0) we have  $g_j = z_i$  for some index  $j \in \{1, \ldots, r\}$ , and hence  $g_j \in \widetilde{Z}$  in Step [8.](#page-6-0)  $\Box$ 

The following example illustrates Algorithm [3.2](#page-6-0) at work. It will also be reconsidered in the next sections.

<span id="page-8-0"></span>**Example 3.4.** Let  $P = \mathbb{Q}[x_1, \ldots, x_{11}]$ , and let *I* be the ideal in *P* generated by the polynomials  $g_1, \ldots, g_9 \in P$  given by

$$
g_1 = x_1 x_4 x_8 x_{11} + x_5 x_6 x_8 + x_5 x_6 x_{10} + x_3 x_6 + x_7 x_8 + x_1 + x_4,
$$
  
\n
$$
g_2 = -x_1^2 x_3^4 - x_1 x_2 x_3 x_6 x_8 x_{11} + x_1^3 x_{10} + x_3 + x_7 + 1,
$$
  
\n
$$
g_3 = x_1 x_2 x_3^2 x_8^2 + x_6 x_7^2 x_8 + x_1 x_3 x_8^2 + x_7 x_8 + x_7 x_{10} + x_2 + x_5,
$$
  
\n
$$
g_4 = -x_1 x_7 x_9 + x_3 x_{11} + x_9,
$$
  
\n
$$
g_5 = x_1 x_4 x_8 x_{11} + x_1^2 x_6 + x_5 x_7,
$$
  
\n
$$
g_6 = x_8 x_{10}^2 + x_7 x_9,
$$
  
\n
$$
g_7 = x_1^2 x_3^4 + x_2^2 x_6^4 + x_1 x_2 x_3^2 x_8^2 + x_1 x_2 x_6^2 x_{10}^2 + x_1 x_2 x_3 x_6 x_8 x_{11},
$$

9

$$
g_8 = x_2^6 + x_1 x_6 x_8 - x_3 x_6,
$$
  

$$
g_9 = x_1^6 + x_1.
$$

We apply Algorithm [3.2](#page-6-0) to check whether  $Z = (x_4, x_5, x_7)$  is a separating tuple of indeterminates for *I*.

- (1) In Step [1,](#page-6-0) we set  $w_1 = \cdots = w_{11} = 0$ ,  $\delta = 6$ , and  $d = 1$ .
- (2) In Step [2,](#page-6-0) we delete all monomials in  $q_1, \ldots, q_9$  not divisible by  $x_4, x_5$ , or  $x_7$ , and obtain

$$
g_1 = x_1 x_4 x_8 x_{11} + x_5 x_6 x_8 + x_5 x_6 x_{10} + x_7 x_8 + x_4, \quad g_2 = x_7,
$$
  
\n
$$
g_3 = x_6 x_7 x_8 + x_7 x_8 + x_7 x_{10} + x_5, \quad g_4 = -x_1 x_7 x_9,
$$
  
\n
$$
g_5 = x_1 x_4 x_8 x_{11} + x_5 x_7, \quad g_6 = x_7 x_9, \quad g_7 = g_8 = g_9 = 0.
$$

We have  $\dim_{\mathbb{O}}(\langle \text{Lin}(g_i) \mid i = 1, \ldots, 9 \rangle_{\mathbb{O}}) = 3 = \#Z$ , so the algorithm does not stop in Step [2.](#page-6-0)

(3) The result of applying Algorithm [3.1](#page-4-1) in Step [7](#page-6-0) is

 $g_1 = x_4 - x_5x_7 + x_5x_6x_8 + x_5x_6x_{10} + x_7x_8$  $g_2 = x_5 + x_6x_7x_8 + x_7x_8 + x_7x_{10}$  $g_3 = x_7$ ,  $g_4 = x_1x_4x_8x_{11} + x_5x_7$ ,  $g_5 = -x_1x_7x_9, \quad g_6 = x_7x_9.$ 

- (4) In Step [8](#page-6-0) we obtain  $\widetilde{Z} = \{x_7\}.$
- (5) Since  $\widetilde{Z} \neq \emptyset$ , Step [13](#page-6-0) sets  $w_7 = 1$  and Step [14](#page-6-0) sets  $Z = (x_4, x_5)$ . Deleting all monomials not divisible by  $x_4$  or  $x_5$  in  $g_1, \ldots, g_6$  in Step [16](#page-6-0) yields

 $g_1 = x_4 - x_5x_7 + x_5x_6x_8 + x_5x_6x_{10}$ ,  $g_2 = x_5$ ,  $g_3 = 0$ ,  $g_4 = x_1x_4x_8x_{11} + x_5x_7$ ,  $g_5 = g_6 = 0$ .

Step [17](#page-6-0) sets *d* to 7, and the loop repeats.

(6) Algorithm [3.1](#page-4-1) returns

$$
g_1 = x_4 - x_5x_7 + x_5x_6x_8 + x_5x_6x_{10},
$$
  
\n
$$
g_2 = x_5, \quad g_3 = x_1x_4x_8x_{11} + x_5x_7.
$$

Step [8](#page-6-0) finds  $\widetilde{Z} = \{x_5\} \neq \emptyset$ , so Step [13](#page-6-0) sets  $w_5 = 7$ , and Step [14](#page-6-0) sets  $Z = (x_4)$ . The deletions in Step [16](#page-6-0) yield  $g_1 = x_4$ ,  $g_2 = 0$ , and  $g_3 = x_1x_4x_8x_{11}$ . Step [17](#page-6-0) sets  $d = 43$ and the loop repeats.

(7) Algorithm [3.1](#page-4-1) returns  $g_1 = x_4$  and  $g_2 = x_1x_4x_8x_{11}$ . We have  $\widetilde{Z} = \{x_4\}$  in Step [8,](#page-6-0) so Step [13](#page-6-0) sets  $w_4 = 43$  and Step [14](#page-6-0) sets  $Z = \emptyset$ . After executing Steps [16](#page-6-0) and [17,](#page-6-0) the loop terminates and the algorithm returns  $W = (0, 0, 0, 43, 7, 0, 1, 0, 0, 0, 0)$ .

Hence there exists an  $(x_4, x_5, x_7)$ -separating tuple of polynomials in *I*.

It is worth noting that the computation of a *τ*-Gröbner basis of *I* from  $g_1, \ldots, g_9$ for an elimination ordering  $\tau$  for  $Z$  is quite hard and takes many hours using computer algebra systems such as  $CoCoA$  (see [\[1\]](#page-26-0)), msolve (see [\[4\]](#page-26-1)), or SageMath (see [\[21\]](#page-27-6)). Algorithm [3.2,](#page-6-0) however, is done in less than a second.

The next example shows an application of Algorithm [3.2](#page-6-0) to an ideal whose linear part is a binomial linear ideal which was studied in [\[14,](#page-27-1) Section 5]. This again shows that our method can work efficiently with rather large examples where any Gröbner basis calculation would be infeasible.

**Example 3.5.** In the polynomial ring  $P = \mathbb{Q}[x_1, \ldots, x_{84}]$ , consider the ideal *I* generated by nonzero entries of the pairwise commutators of the following three matrices

> $\int 0$   $x_3$   $x_5$  0 0 0  $x_{12}$  $\overline{\phantom{a}}$ 0 *x*<sup>15</sup> *x*<sup>17</sup> 0 0 0 *x*<sup>24</sup> 0 *x*<sup>27</sup> *x*<sup>29</sup> 0 0 0 *x*<sup>36</sup> 1 *x*<sup>39</sup> *x*<sup>41</sup> 0 0 0 *x*<sup>48</sup> 0 *x*<sup>51</sup> *x*<sup>53</sup> 1 0 0 *x*<sup>60</sup> 0 *x*<sup>63</sup> *x*<sup>65</sup> 0 1 0 *x*<sup>72</sup> 0 *x*<sup>75</sup> *x*<sup>77</sup> 0 0 1 *x*<sup>84</sup>  $\setminus$  $\overline{\phantom{a}}$ *,*  $\int 0$  *x*<sub>2</sub> *x*<sub>4</sub> *x*<sub>5</sub> *x*<sub>7</sub> *x*<sub>9</sub> *x*<sub>11</sub>  $\overline{\phantom{a}}$ 0 *x*<sup>14</sup> *x*<sup>16</sup> *x*<sup>17</sup> *x*<sup>19</sup> *x*<sup>21</sup> *x*<sup>23</sup> 1 *x*<sup>26</sup> *x*<sup>28</sup> *x*<sup>29</sup> *x*<sup>31</sup> *x*<sup>33</sup> *x*<sup>35</sup> 0 *x*<sup>38</sup> *x*<sup>40</sup> *x*<sup>41</sup> *x*<sup>43</sup> *x*<sup>45</sup> *x*<sup>47</sup> 0 *x*<sup>50</sup> *x*<sup>52</sup> *x*<sup>53</sup> *x*<sup>55</sup> *x*<sup>57</sup> *x*<sup>59</sup> 0 *x*<sup>62</sup> *x*<sup>64</sup> *x*<sup>65</sup> *x*<sup>67</sup> *x*<sup>69</sup> *x*<sup>71</sup> 0 *x*<sup>74</sup> *x*<sup>76</sup> *x*<sup>77</sup> *x*<sup>79</sup> *x*<sup>81</sup> *x*<sup>83</sup>  $\setminus$  $\overline{\phantom{a}}$ *,*  $\int 0$  *x*<sub>1</sub> *x*<sub>2</sub> *x*<sub>3</sub> *x*<sub>6</sub> *x*<sub>8</sub> *x*<sub>10</sub>  $\overline{\phantom{a}}$ 1 *x*<sup>13</sup> *x*<sup>14</sup> *x*<sup>15</sup> *x*<sup>18</sup> *x*<sup>20</sup> *x*<sup>22</sup> 0 *x*<sup>25</sup> *x*<sup>26</sup> *x*<sup>27</sup> *x*<sup>30</sup> *x*<sup>32</sup> *x*<sup>34</sup> 0 *x*<sup>37</sup> *x*<sup>38</sup> *x*<sup>39</sup> *x*<sup>42</sup> *x*<sup>44</sup> *x*<sup>46</sup> 0 *x*<sup>49</sup> *x*<sup>50</sup> *x*<sup>51</sup> *x*<sup>54</sup> *x*<sup>56</sup> *x*<sup>58</sup> 0 *x*<sup>61</sup> *x*<sup>62</sup> *x*<sup>63</sup> *x*<sup>66</sup> *x*<sup>68</sup> *x*<sup>70</sup> 0 *x*<sup>73</sup> *x*<sup>74</sup> *x*<sup>75</sup> *x*<sup>78</sup> *x*<sup>80</sup> *x*<sup>82</sup>  $\setminus$  $\begin{array}{c} \hline \end{array}$ *.*

Then a system of generators of *I* consists of 126 quadratic polynomials without constant, and so  $I \subseteq \mathfrak{M}$ . The linear part of *I* has dimension 57 and generates a binomial linear ideal. Using the method mentioned in Remark [2.4.](#page-4-2)b, we find that the following tuple *Z* of 57 indeterminates

 $(x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8, x_9, x_{10}, x_{11}, x_{12}, x_{18}, x_{19}, x_{20}, x_{21}, x_{22}, x_{23}, x_{30},$  $x_{31}, x_{32}, x_{33}, x_{34}, x_{35}, x_{37}, x_{38}, x_{40}, x_{42}, x_{43}, x_{44}, x_{45}, x_{46}, x_{47}, x_{49}, x_{50}, x_{52}, x_{54}, x_{55},$  $x_{56}, x_{57}, x_{58}, x_{59}, x_{61}, x_{62}, x_{64}, x_{66}, x_{67}, x_{68}, x_{69}, x_{70}, x_{71}, x_{78}, x_{79}, x_{80}, x_{81}, x_{82}, x_{83})$ 

is a possible candidate for a separating tuple of indeterminates for *I*. When we apply Algorithm [3.2,](#page-6-0) it shows that *Z* is indeed a separating tuple of indeterminates for *I* and returns the weight tuple

> (127*,* 127*,* 15*,* 127*,* 15*,* 31*,* 31*,* 31*,* 31*,* 31*,* 31*,* 15*,* 1*,* 1*,* 3*,* 3*,* 7*,* 7*,* 1*,* 1*,* 3*,* 3*,* 7*,* 7*,* 63*,* 63*,* 63*,* 15*,* 15*,* 31*,* 31*,* 31*,* 31*,* 31*,* 31*,* 31*,* 1*,* 1*,* 15*,* 15*,* 31*,* 31*,* 15*,* 15*,* 15*,* 1*,* 1*,* 3*,* 3*,* 15*,* 15*,* 1*,* 1*,* 3*,* 3*,* 7*,* 7)*.*

Notice that we also have  $\#Z = 57 = \dim_K(\text{Ling}(I))$ . Thus the *Z*-separating reembedding of *I* is an optimal re-embedding by [\[14,](#page-27-1) Corollary 2.8].

Moreover, the closed subscheme of  $\mathbb{A}_{\mathbb{O}}^{84}$  defined by *I* is the border basis scheme associated to a certain order ideal (see [\[3,](#page-26-2) Example 8]). Using techniques relying on Pommaret bases, it is shown in [\[3\]](#page-26-2) that this scheme can be embedded into  $\mathbb{A}^{42}_{\mathbb{O}}$ , while our method yields an optimal embedding into  $\mathbb{A}_{\mathbb{O}}^{27}$ .

### <span id="page-11-0"></span>**4 Optimized Checking of Separating Indeterminates**

In this section we discuss an optimization of Algorithm [3.2.](#page-6-0) Instead of simply interreducing the polynomials  $g_1, \ldots, g_r$  linearly using Algorithm [3.1](#page-4-1) in Step [7,](#page-6-0) we first extend them with some polynomials contained in  $P_{\geq 2}$ . This allows Algorithm [4.1](#page-11-1) to succeed in cases where Algorithm  $3.2$  fails.

<span id="page-11-1"></span>**Algorithm 4.1.** *Let*  $I = \langle g_1, \ldots, g_r \rangle$  *be a proper ideal in*  $P$ *, where*  $g_1, \ldots, g_r \in P \setminus \{0\}$ *,* and let  $Z = (z_1, \ldots, z_s)$  be a tuple of distinct indeterminates in X. Consider the *following modifications of Algorithm [3.2.](#page-6-0)*

*(I) Replace Step [7](#page-6-0) by the following sequence of steps.*

*[7a](#page-6-0): Form the set*  $H = \{x_i g_j \mid x_i \in X \setminus Z \text{ and } j \in \{1, ..., r\}\}.$ 

*[7b](#page-6-0): Let*  $\tau$  *be a degree-compatible term ordering. Compute a K-basis*  $\{h_1, \ldots, h_m\}$  *of the space*  $\langle H \rangle_K$  *such that*  $LT_{\tau}(h_i) \neq LT_{\tau}(h_j)$  *for*  $i \neq j$ *.* 

*[7c](#page-6-0): Compute the intersection*  $\{q_1, \ldots, q_u\} = \{h_1, \ldots, h_m\} \cap P_{\leq \delta}$ *.* 

[7d](#page-6-0): Apply Algorithm [3.1](#page-4-1) to Z and  $g_1, \ldots, g_r, q_1, \ldots, q_u$ . Call the result  $g_1, \ldots, g_r$  again.

*(II) Moreover, replace Step [17](#page-6-0) by the following step:*

[17:](#page-6-0) *Replace*  $d$  *by*  $2\delta d + 1$ *.* 

*Then the resulting sequence of instructions is an algorithm which returns either "Fail" or a tuple of non-negative weights*  $W = (w_1, \ldots, w_n) \in \mathbb{N}^n$ . If it returns a tuple W, *then there is a Z-separating tuple of polynomials*  $(f_1, \ldots, f_s)$  *for I such that every term ordering*  $\sigma$  *which is compatible with the grading given by W satisfies*  $LT_{\sigma}(f_i) = z_i$  *for*  $i = 1, \ldots, s$ *.* 

*Proof.* The finiteness of the algorithm follows in the same way as in the proof of Algorithm [3.2,](#page-6-0) so we only show its correctness whenever it returns a weight tuple  $W = (w_1, \ldots, w_s)$ . Also observe that Step [7b](#page-6-0) can be executed e.g. by executing Algorithm [3.1](#page-4-1) on the input *H* and the empty tuple.

Let  $\delta = \max{\{\deg(g_1), \ldots, \deg(g_r)\}}$  $\delta = \max{\{\deg(g_1), \ldots, \deg(g_r)\}}$  $\delta = \max{\{\deg(g_1), \ldots, \deg(g_r)\}}$  as in Step 1 of the algorithm. For  $k \in \mathbb{N}$ , let  $U_k = I_{\leq \delta + k}$  be the *K*-vector space of all polynomials in *I* of degree  $\leq \delta + k$ . At any state of the algorithm, let  $W = (w_1, \ldots, w_n)$ , and for every  $\ell \geq 0$  let  $V_{\ell}$  be the *K*vector space generated by all terms in  $K[X \setminus Z]_{\leq \delta + \ell}$  having  $W$ -weight  $\leq \ell$ . Notice that in every state of the algorithm, except between Steps [13](#page-6-0) and [14,](#page-6-0) every indeterminate in *X*  $\setminus$  *Z* has already been assigned a weight. So, if a term is in  $V_\ell$ , then its *W*-weight does not change in a later step of the algorithm, even if some weights  $w_k$  are adjusted in a later execution of Step [13.](#page-6-0) Moreover, both sequences  $(U_k)_{k\in\mathbb{N}}$  and  $(V_\ell)_{\ell\in\mathbb{N}}$  are increasing sequences, i.e.,  $U_k \subseteq U_{k+1}$  and  $V_\ell \subset V_{\ell+1}$  for all  $k, \ell \in \mathbb{N}$ .

Next we prove the following five claims.

- (1) At the start of the first iteration of the loop in Steps [6-18,](#page-6-0) we have  $g_1, \ldots, g_r \in$  $U_0 + V_0$ .
- (2) If  $g_1, \ldots, g_r \in U_m + V_{m'}$  for some  $m, m' \in \mathbb{N}$  at the start of an iteration of the loop, then we have  $g_1, \ldots, g_r \in U_{m+1} + V_{m'+(d-1)/2}$  after the execution of Steps [7a-7d](#page-6-0).
- (3) If  $g_1, \ldots, g_r \in U_m + V_{m'}$  for some  $m, m' \in \mathbb{N}$  after an execution of Steps [7a-7d](#page-6-0) during an iteration of the loop, then we have  $g_1, \ldots, g_r \in U_m + V_{m'} + V_{\delta d}$  after the execution of Step [16.](#page-6-0)
- (4) For every  $k \in \mathbb{N}$  such that there exists a *k*-th iteration of the loop in Steps [6-18,](#page-6-0) we have  $g_1, \ldots, g_r \in U_{k-1} + V_{(d-1)/2}$  at the start of the *k*-th iteration.
- (5) For every  $k \in \mathbb{N}$  such that there exists a *k*-th iteration of the loop in Steps [6-18,](#page-6-0) we have  $g_1, \ldots, g_r \in U_k + V_{d-1}$  after the execution of Steps [7a-7d](#page-6-0) in the *k*-th iteration of the loop.

To show (1), observe that all terms deleted in Step [2](#page-6-0) are elements of  $K[X \setminus Z]_{\leq \delta}$ and have *W*-weight 0. This shows  $g_1, \ldots, g_r \in U_0 + V_0$  at the start of the first iteration of the loop in Steps [6-18.](#page-6-0)

For a proof of (2), assume that we are after the execution of Step [7c](#page-6-0), and let  $U = \langle H \rangle_K \cap P_{\leq \delta}$ . We show the following.

(2.1) The polynomials  $q_1, \ldots, q_u$  computed in Step [7c](#page-6-0) form a *K*-basis of *U*.

(2.2) If  $g_1, \ldots, g_r \in U_m + V_{m'}$  for some  $m, m' \in \mathbb{N}$  before the execution of Step [7a](#page-6-0), then we have  $U \subseteq U_{m+1} + V_{m'+(d-1)/2}$  after the execution of Step [7c](#page-6-0).

To verify (2.1), we note that  $q_1, \ldots, q_u \in U$ . Let  $f \in U$  and suppose without loss of generality that  $LT_{\tau}(h_1) <_{\tau} \cdots <_{\tau} LT_{\tau}(h_m)$  in Step [7b](#page-6-0). Since  $\tau$  is a degree-compatible term ordering, we have  $\{q_1, \ldots, q_u\} = \{h_1, \ldots, h_u\}$ . As  $f \in \langle h_1, \ldots, h_m \rangle_K$  and the leading terms of  $h_1, \ldots, h_m$  are pairwise distinct, there is an index  $j \in \{1, \ldots, m\}$ such that  $LT_{\tau}(f) = LT_{\tau}(h_j)$ . It follows that  $f \in \langle h_1, \ldots, h_j \rangle_K$ , because, for all  $i > j$ , we have  $\deg(h_i) > \deg(f)$ , and hence  $LT_\tau(h_i) >_\tau LT_\tau(f)$ . Moreover,  $f \in P_{\leq \delta}$  implies  $j \leq u$ . This yields  $f \in \langle h_1, \ldots, h_u \rangle_K = \langle q_1, \ldots, q_u \rangle_K$ , and (2.1) follows.

For a proof of (2.2), it suffices to show that in Step [7a](#page-6-0) we have  $x_i g_j \in U_{m+1}$  + *V*<sup>*m*</sup><sup> $t$ </sup>+(*d*−1)<sup>*/*2</sup> for  $x_i \in X \setminus Z$  and  $j \in \{1, \ldots, r\}$ . By the assumption,  $g_j \in U_m + V_m$ <sup>*i*</sup>, so there are polynomials  $u_j \in U_m$  and  $v_j \in V_{m'}$  with  $g_j = u_j + v_j$ . Every term in the support of  $v_j$  has *W*-weight  $\leq m'$ . Moreover, the *W*-weight of  $x_i$  was assigned in a previous iteration of the loop, so it is at most  $(d-1)/2\delta$ , and hence smaller than  $(d-1)/2$ . Altogether, the *W*-weight of every term in the support of  $x_i v_j$  is at most  $m' + (d-1)/2$  and we conclude that  $x_i v_j \in V_{m'+(d-1)/2}$ . It follows that

$$
x_i g_j = x_i u_j + x_i v_j \in x_i \cdot U_m + V_{m'+(d-1)/2} \subseteq U_{m+1} + V_{m'+(d-1)/2}.
$$

Hence we get  $U \subseteq U_{m+1} + V_{m'+(d-1)/2}$ . Now observe that after Step [7c](#page-6-0) we have

 $g_1, \ldots, g_r, q_1, \ldots, q_u \in (U_m + V_{m'}) \cup (U_{m+1} + V_{m'+(d-1)/2}) = U_{m+1} + V_{m'+(d-1)/2},$ 

so after the execution of Step [7d](#page-6-0), we have  $g_1, \ldots, g_r \in U_{m+1} + V_{m'+(d-1)/2}$ . This shows Claim  $(2)$ .

To show (3), suppose that  $g_1, \ldots, g_r \in U_m + V_{m'}$  after an execution of Step [7d](#page-6-0). During the execution of Steps [8-15,](#page-6-0) only  $V_{m'}$  is extended. So, before the execution of Step [16,](#page-6-0) we still have  $g_1, \ldots, g_r \in U_m + V_{m'}$ . Let  $j \in \{1, \ldots, r\}$ , let  $c_1 t_1, \ldots, c_e t_e$  be the monomials deleted from  $g_j$  in Step [16,](#page-6-0) where  $c_1, \ldots, c_e \in K$  and  $t_1, \ldots, t_e \in \mathbb{T}^n$ are terms, and let  $g'_j = g_j - c_1 t_1 - \cdots - c_e t_e$  be the resulting polynomial obtained from  $g_j$  after their deletion. Notice that, for  $i = 1, \ldots, e$ , we have  $t_i \in K[X \setminus Z]$  and  $deg(t_i) \leq \delta$  by (2.1), so all  $t_1, \ldots, t_e$  have weight  $\leq \delta d$ . This shows  $t_1, \ldots, t_e \in V_{\delta d}$ . Hence  $g_j \in U_m + V_{m'}$  implies  $g'_j \in U_m + V_{m'} + V_{\delta d}$ . Consequently, after the execution of Step [16,](#page-6-0) we have  $g_j \in U_m + V_{m'} + V_{\delta d}$  for all  $i \in \{1, ..., r\}$ .

Next Claim (4) is shown inductively as follows. For  $k = 1$ , it holds by (1). Moreover, let  $k \in \mathbb{N}$  such that there exist a k-th and a  $(k+1)$ -st iteration of the loop, and suppose that  $g_1, \ldots, g_r \in U_{k-1} + V_{(d-1)/2}$  at the start of the *k*-th iteration. Then (2) shows  $g_1, \ldots, g_r \in U_k + V_{(d-1)/2 + (d-1)/2} = U_k + V_{d-1}$  after the execution of Steps [7a-7d](#page-6-0) of the iteration, and (3) implies

$$
g_1, \ldots, g_r \in U_k + V_{d-1} + V_{\delta d} = U_k + V_{\delta d}
$$

after the execution of Step [16.](#page-6-0) Therefore, after the adjustment of *d* in Step [17](#page-6-0) and at the start of the  $(k + 1)$ -st loop, we have  $g_1, \ldots, g_r \in U_k + V_{(d-1)/2}$ . This shows (4).

To prove (5), we note that at the start of the *k*-th iteration of the loop in Steps [6-](#page-6-0) [18,](#page-6-0) we have  $g_1, \ldots, g_r \in U_{k-1} + V_{(d-1)/2}$  by (4). Now (2) says that, after the execution of Steps [7a-7d](#page-6-0), we have  $g_1, \ldots, g_r \in U_k + V_{(d-1)/2 + (d-1)/2} = U_k + V_{d-1}$ .

Finally, we combine everything and finish the correctness proof of the algorithm. For every  $z_i \in Z$ , we eventually find  $g_j = z_i$  for some index  $j \in \{1, \ldots, r\}$ , where we are in Steps [12-15](#page-6-0) of the *k*-th iteration of the loop for some  $k \geq 1$ . Assume that the weight of  $z_i$  is set to *d* in this iteration. By Claim (5), we have  $g_j \in U_k + V_{d-1}$  at this point, so there are  $f_j \in U_k$  and  $v_j \in V_{d-1}$  with  $g_j = f_j + v_j$ . Hence  $f_j = g_j - v_j = z_i - v_j$ , where every term in  $v_j$  has *W*-weight  $\leq d-1$ , and where  $z_i$  has weight *d*. This shows  $LT_{\sigma}(f_i) = z_i$  for every term ordering  $\sigma$  that is compatible with the grading given by *W*. Consequently,  $(f_1, \ldots, f_s)$  is a *Z*-separating tuple of polynomials.

Algorithm [4.1](#page-11-1) sometimes verifies separating tuples of indeterminates of larger lengths than Algorithm [3.2,](#page-6-0) as the following example shows.

<span id="page-13-0"></span>**Example 4.2.** Let  $P = \mathbb{Q}[x_1, \ldots, x_{11}]$  and let *I* be the ideal given in Example [3.4.](#page-8-0) There we used Algorithm [3.2](#page-6-0) to verify that  $(x_4, x_5, x_7)$  is a separating tuple for *I*.

Now we apply Algorithm [4.1](#page-11-1) to find a larger separating tuple of indeterminates for the ideal *I*. More precisely, consider  $Z = (x_4, x_5, x_7, x_9)$ .

After deleting all monomials not divisible by indeterminates from *Z* in Step [16,](#page-6-0) we are left with

$$
g_1 = x_4 + x_1x_4x_8x_{11} + x_5x_6x_8 + x_5x_6x_{10} + x_7x_8, \quad g_2 = x_7,
$$
  
\n
$$
g_3 = x_5 + x_6x_7x_8 + x_7x_8 + x_7x_{10}, \quad g_4 = x_9 - x_1x_7x_9,
$$
  
\n
$$
g_5 = x_1x_4x_8x_{11} + x_5x_7, \quad g_6 = x_7x_9, \quad g_7 = g_8 = g_9 = 0.
$$

At this point, Steps [7a-7d](#page-6-0) in Algorithm [4.1](#page-11-1) enable us to reduce  $g_4$  against  $x_1g_6$  and get the new polynomial  $g_4 = x_9$ . Hence we can assign weight 1 to both  $x_7$  and  $x_9$  in the first iteration of the loop.

The remaining part of the algorithm operates similarly as in Example [3.4.](#page-8-0) However, in this case we find the weight tuple  $(0, 0, 0, 157, 13, 0, 1, 0, 1, 0, 0)$  and conclude that the tuple  $Z = (x_4, x_5, x_7, x_9)$  is a separating tuple of indeterminates for *I*.

On the other hand, if we apply Algorithm [3.2](#page-6-0) to  $g_1, \ldots, g_9$  and *Z*, then we cannot eliminate the term  $x_1x_7x_9$  in Supp $(q_4)$ , which leads to a "Fail" in Algorithm [3.2.](#page-6-0)

Let us finish this discussion with a small optimization of Algorithm [4.1.](#page-11-1)

<span id="page-14-0"></span>**Remark 4.3.** In the setting of Algorithm [4.1,](#page-11-1) to construct a *K*-basis  $\{q_1, \ldots, q_u\}$ of the *K*-vector space  $\langle H \rangle_K \cap P_{\leq \delta}$ , as required in Steps [7b-7c](#page-6-0), without introducing a degree-compatible term ordering  $\tau$ , one can alternatively use the following instructions:

- (1) Write  $H' = (h_1, \ldots, h_m)$  where  $H = \{h_1, \ldots, h_m\}$  with  $m = (n s)r$ . Compute the set  $\{t_1, \ldots, t_e\}$  of all terms of degree  $\geq \delta$  in the support of one of the elements in *H*.
- (2) Write  $h_j = h'_j + \sum_{k=1}^e a_{jk}t_k$ , where  $a_{jk} \in K$  and  $\deg(h'_j) \leq \delta$  for all  $j = 1, \ldots, m$ , and form the matrix  $A = (a_{kj}) \in Mat_{e,m}(K)$ .
- (3) Compute a *K*-basis  $\{v_1, \ldots, v_u\}$  of Ker(*A*), and let  $q_k = H \cdot v_k$  for  $k = 1, \ldots, u$ .

The advantage of this method is that the matrix *A* may be smaller than the cofficient matrix of  $h_1, \ldots, h_m$ . This may make the computation of this step more efficient than the computation in Step [7b](#page-6-0).

### <span id="page-14-1"></span>**5 Finding** *Z***-Separating Tuples of Polynomials**

The following algorithm provides a *Z*-separating tuple of polynomials in the ideal *I* in the case when Algorithm [3.2](#page-6-0) is successful.

#### <span id="page-14-2"></span>**Algorithm 5.1. (Computing** *Z***-Separating Polynomials)**

*Let*  $g_1, \ldots, g_r \in P$  *be generators of a proper ideal I in P, and let Z be a tuple of distinct indeterminates in X such that Algorithm* [3.2](#page-6-0) *returns a weight tuple*  $W \in \mathbb{N}^n$ . *Moreover, let σ be a term ordering on P which is compatible with the grading given by W. Consider the following sequence of instructions.*

- *1: Compute*  $T = (t_1, \ldots, t_m)$  *where*  $\{t_1, \ldots, t_m\}$  *is the set of terms in the union of the supports of*  $g_1, \ldots, g_r$ *, ordered such that*  $t_1 >_\sigma \cdots >_\sigma t_m$ *.*
- 2: Form the coefficient matrix  $M \in Mat_{r,m}(K)$  of  $g_1, \ldots, g_r$  with respect to terms *in T.*
- *3: Compute the matrix*  $N \in Mat_{r',r}(K)$  *such that*  $N \cdot M \in Mat_{r',m}(K)$  *is in reduced row echelon form and has no zero rows.*
- 4*: Compute*  $(g'_1, \ldots, g'_{r'})^{\text{tr}} = N \cdot (g_1, \ldots, g_r)^{\text{tr}}$ .
- 3: Compute  $(g_1, \ldots, g_{r'})$   $N \cdot (g_1, \ldots, g_r)$ .<br>5: For  $i = 1, \ldots, s$ , let  $f_i \in \{g'_1, \ldots, g'_{r'}\}$  be the element with  $LT_{\sigma}(f_i) = z_i$ . Return  $(f_1, \ldots, f_s)$ .

*This is an algorithm which computes a Z-separating tuple of polynomials*  $(f_1, \ldots, f_s)$ *in I.*

*Proof.* First we note that if the algorithm is executed correctly, then the resulting polynomials  $f_1, \ldots, f_s$  form indeed a *Z*-separating tuple of polynomials in *I*, as they are by construction elements of *I* which satisfy  $LT_{\sigma}(f_i) = z_i$  for  $i = 1, ..., s$ . It remains to prove that the algorithm is always able to find  $f_1, \ldots, f_s$  as claimed in Step 4.

Let  $z_i \in Z$ . By Proposition [3.3,](#page-7-0) there is a polynomial  $f'_i \in \langle g_1, \ldots, g_r \rangle_K$  with  $LT_{\sigma}(f'_{i}) = z_{i}$ . Since *N* is an invertible matrix, we also have  $f'_{i} \in \langle g'_{1}, \ldots, g'_{r'} \rangle_{K}$ , and since  $N \cdot M$  is in reduced row echelon form, the leading terms of  $g'_1, \ldots, g'_{r'}$  are pairwise distinct. Hence there exists an index  $j \in \{1, \ldots, r'\}$  such that  $LT_{\sigma}(g'_j) = LT_{\sigma}(f'_i) = z_i$ . This shows that the algorithm correctly finds  $f_i = g'_j$ .  $\Box$ 

**Example 5.2.** Let  $g_1, \ldots, g_9$  be the polynomials given in Example [3.4,](#page-8-0) and let  $Z =$  $(x_4, x_5, x_7)$ . The application of Algorithm [3.2](#page-6-0) in Example [3.4](#page-8-0) yielded the weight tuple  $W = (0, 0, 0, 43, 7, 0, 1, 0, 0, 0, 0)$ . As in [\[15,](#page-27-7) Definition 1.4.11], we let  $\sigma$  be the ordering on *P* represented by the matrix

$$
A = \left(\begin{smallmatrix} 0 & 0 & 0 & 43 & 7 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{smallmatrix}\right)
$$

*.*

Then  $\sigma$  is a term ordering on P which is compatible with the grading given by *W*. An application of Algorithm [5.1](#page-14-2) to  $g_1, \ldots, g_9$ , *Z* and  $\sigma$  gives us the *Z*-separating tuple  $(f_1, f_2, f_3)$  of polynomials in *I*, where

$$
f_1 = x_4 - x_5x_7 + x_5x_6x_8 + x_5x_6x_{10} + x_7x_8 - x_1^2x_6 + x_3x_6 + x_1,
$$
  
\n
$$
f_2 = x_5 + x_6x_7^2x_8 + x_7x_8 + x_7x_{10} + x_1x_2x_3^2x_8^2 + x_1x_3x_8^2 + x_2,
$$
  
\n
$$
f_3 = x_7 + x_2^2x_6^4 + x_1x_2x_3^2x_8^2 + x_1x_2x_6^2x_{10}^2 + x_1^3x_{10} + x_3 + 1.
$$

Notice that in the setting of Algorithm [4.1,](#page-11-1) it is somewhat trickier to find actual separating polynomials. Let us describe how to do this.

<span id="page-15-0"></span>**Remark 5.3.** If Algorithm [3.2](#page-6-0) is successful, then we can apply Algorithm [5.1](#page-14-2) in order to find a *Z*-separating tuple of polynomials. However, if Algorithm [4.1](#page-11-1) is successful, then it does not guarantee the existence of a *Z*-separating tuple of polynomials in the *K*-vector space  $\langle q_1, \ldots, q_r \rangle_K$ . Hence we can not apply Algorithm [5.1](#page-14-2) to compute such a tuple. In this case, in order to compute a *Z*-separating tuple of polynomials in *I*, we can mimic all linear operations executed on  $g_1, \ldots, g_r$  on polynomials  $G_1, \ldots, G_r$ as follows.

At the start of the algorithm, let  $G_1, \ldots, G_r$  be copies of the input polynomials *g*<sub>1</sub>*,..., g<sub>r</sub></sub>. In every execution of Steps [7a-7c](#page-6-0), compute the matrix <i>A* ∈ Mat<sub> $(n-s)r,u$ </sub> $(K)$ such that

$$
(q_1, \ldots, q_u) = (x_i g_j \mid x_i \in X \setminus Z \text{ and } j \in 1, \ldots, r) \cdot A
$$

and let

$$
(Q_1, \ldots, Q_u) = (x_i G_j \mid x_i \in X \setminus Z \text{ and } j \in 1, \ldots, r) \cdot A.
$$

16

Mimic the linear transformation performed on  $g_1, \ldots, g_r, q_1, \ldots, q_u$  in Step [7d](#page-6-0) on  $G_1, \ldots, G_r, Q_1, \ldots, Q_r$ , and re-name the resulting polynomials as  $G_1, \ldots, G_r$  again. If  $x_k = z_i$  in Step [13,](#page-6-0) let  $f_i = G_k$ .

Whenever Algorithm [4.1](#page-11-1) successfully returns a weight tuple *W*, we obtain a *Z*separating tuple  $(f_1, \ldots, f_s)$  of polynomials in *I* in this way.

The next remark shows how to obtain a coherently *Z*-separating tuple from a *Z*-separating tuple of polynomials.

<span id="page-16-0"></span>**Remark 5.4.** Assume that  $(f_1, \ldots, f_s)$  is a *Z*-separating tuple of polynomials in *I* obtained by Algorithm [5.1](#page-14-2) or Remark [5.3](#page-15-0) after a successful run of Algorithm [3.2](#page-6-0) or [4.1,](#page-11-1) respectively. Let *W* be the corresponding output of the latter algorithm and let  $\sigma$  be a term ordering on *P* which is compatible with the grading given by *W*.

If we renumber indices such that  $z_1 <_{\sigma} z_2 <_{\sigma} \cdots <_{\sigma} z_s$ , then  $f_i$  is of the form  $f_i = z_i - p_i$ , where  $p_i \in K[X \setminus Z][z_1, \ldots, z_{i-1}] \leq \delta$  for  $i = 1, \ldots, s$ . By substituting  $z_1 \mapsto p_1$  in  $f_2$ , we obtain a polynomial of the from  $\overline{f'_2} = z_2 - p'_2$ , where  $p'_2 \in K[X \setminus Z]_{\leq \delta^2}$ . Next we continue by substituting  $z_1 \mapsto p_1$  and  $z_2 \mapsto p_2'$  in  $f_3$  and so on. In this way, we eventually get polynomials  $f'_1 = z_1 - h'_1, \ldots, f'_s = z_s - h'_s$  with  $h'_1, \ldots, h'_s \in K[X \setminus Z]$ , i.e., a coherently *Z*-separating tuple  $(f'_1, \ldots, f'_s)$  of polynomials in *I* that defines a *Z*-separating re-embedding of *I*.

Let us apply this remark to our running example.

**Example 5.5.** Let *P* and *I* be defined as in Example [3.4,](#page-8-0) let  $Z = (x_4, x_5, x_7, x_9)$ , and let  $Y = X \setminus Z$ . In Example [4.2](#page-13-0) we found out that Z is a separating tuple of indeterminates for *I*. Using Remark [5.3,](#page-15-0) we compute a *Z*-separating tuple  $(f_1, \ldots, f_4)$ of polynomials in *I* where

$$
f_1 = x_7 - x_1^2 x_3^4 - x_1 x_2 x_3 x_6 x_8 x_{11} + x_1^3 x_{10} + x_3 + 1,
$$
  
\n
$$
f_2 = x_9 + x_1 x_8 x_{10}^2 + x_3 x_{11},
$$
  
\n
$$
f_3 = x_5 + x_1 x_2 x_3^2 x_8^2 + x_6 x_7^2 x_8 + x_1 x_3 x_8^2 + x_7 x_8 + x_7 x_{10} + x_2,
$$
  
\n
$$
f_4 = x_4 - x_1^2 x_6 + x_5 x_6 x_8 + x_5 x_6 x_{10} + x_3 x_6 - x_5 x_7 + x_7 x_8 + x_1.
$$

Write  $p_1 = x_7 - f_1$  and  $p_2 = x_9 - f_2$ . If we substitute  $x_7$  with  $p_1$  and  $x_9$  with  $p_2$  in *f*3, we obtain

$$
f_3' = x_5 - x_1 x_2 x_3^2 x_8^2 - x_6 x_8 p_1^2 - x_1 x_3 x_8^2 - x_8 p_1 - x_{10} p_1 + x_2.
$$

Next, substituting  $x_7$ ,  $x_9$  and  $x_5$  by  $p_1$ ,  $p_2$  and  $p_3 = x_5 - f'_3$ , respectively, into  $f_4$  yields

$$
f_4' = x_4 - x_1^2 x_6 + p_3 x_6 x_8 + p_3 x_6 x_{10} + x_3 x_6 - p_3 p_1 + p_1 x_8 + x_1.
$$

Altogether, the tuple  $(f_1, f_2, f'_3, f'_4)$  is a coherently *Z*-separating tuple of polynomials in *I* which defines a *Z*-separating re-embedding of  $P/I$  into  $K[Y]/(I \cap K[Y])$ . If we now substitute  $x_4$ ,  $x_5$ ,  $x_7$  and  $x_9$  with  $p_1$ ,  $p_2$ ,  $p_3$ , and  $p_4 = x_4 - f'_4$ , respectively, in

17

the generators  $g_1, \ldots, g_9$  of *I*, we obtain polynomials  $\bar{g}_1, \ldots, \bar{g}_9 \in K[Y]$  which are a generating set of  $I \cap K[Y]$ .

### <span id="page-17-0"></span>**6 Checking Separating Boolean Indeterminates**

Throughout this section we let  $\mathbb{F}_2 = \mathbb{Z}/2\mathbb{Z}$ , let  $P = \mathbb{F}_2[X_1, \ldots, X_n]$  be the polynomial ring over  $\mathbb{F}_2$  in the indeterminates  $X_1, \ldots, X_n$ , and let  $\mathbb{B}_n = P/\mathbb{I}_n$  be the **ring of Boolean polynomials**. Here  $\mathbb{I}_n = \langle X_1^2 - X_1, \ldots, X_n^2 - X_n \rangle$  is the field ideal of *P*. For  $i \in \{1, \ldots, n\}$ , we denote the residue class of  $X_i$  in  $\mathbb{B}_n$  by  $x_i$ . These residue classes  $x_1, \ldots, x_n$  are also referred to as **Boolean indeterminates**.

The goal of this section is to introduce (coherently) separating Boolean polynomials and to devise algorithms for checking whether given tuples of Boolean indeterminates are separating, and in the positive case for computing the corresponding separating Boolean polynomials. For basic facts about Boolean polynomials, we refer the reader to [\[6\]](#page-26-3) or [\[9,](#page-27-9) Sec. 2.10].

It is well-known (see e.g. [\[6,](#page-26-3) Theorem 2.1.2]) that every Boolean polynomial  $f \in \mathbb{B}_n$ has a unique representative  $F \in P$  that is a sum of square-free terms, i.e., terms of the form  $X_1^{\alpha_1} \cdots X_n^{\alpha_n}$  with  $\alpha_i \in \{0,1\}$ . In this case, the polynomial *F* is called the **canonical representative** of *f*. We write  $\deg(f) = \deg(F)$  and  $\text{Supp}(f) =$  ${t + \mathbb{I}_n \mid t \in \text{Supp}(F)}$ . Moreover, given a term ordering  $\sigma$  on *P*, we let  $LT_{\sigma}(f)$  =  $LT_{\sigma}(F) + \mathbb{I}_n$  and call it the **leading term** of the Boolean polynomial *f* with respect to  $\sigma$ . We also write  $\text{NR}_{\sigma,G}(f) = \text{NR}_{\sigma,(G_1,\ldots,G_r,X_1^2-X_1,\ldots,X_n^2-X_n)}(F) + \mathbb{I}_n$  for the normal remainder of f with respect to a tuple  $G = (g_1, \ldots, g_r) \in \mathbb{B}_n^r$ , where  $G_i$  is the canonical representative of  $g_i$  for  $i = 1, \ldots, r$ . This allows us also to define a **Boolean**  $\sigma$ -**Gröbner basis** of *I* as a finite set  $G \subseteq I$  that satisfies  $\langle \mathrm{LT}_{\sigma}(g) | g \in G \rangle = \mathrm{LT}_{\sigma}(I)$  $\langle \mathrm{LT}_{\sigma}(f) | f \in I \rangle$ .

In the following, let  $X = (x_1, \ldots, x_n)$  be the tuple of all Boolean indeterminates in  $\mathbb{B}_n$ , and let  $Z = (z_1, \ldots, z_s)$  be a tuple of distinct Boolean indeterminates from X. In analogy to Definition [2.2,](#page-3-0) the tuple *Z* is called a **separating tuple of Boolean indeterminates** for a proper ideal *I* in  $\mathbb{B}_n$ , if there exist a term ordering  $\sigma$  and a tuple  $F = (f_1, \ldots, f_s)$  of Boolean polynomials in *I* such that  $LT_{\sigma}(f_i) = z_i$  for  $i = 1, \ldots, s$ . The tuple *F* is then called a *Z***-separating tuple of Boolean polynomials** in *I*. Whenever such a tuple *F* satisfies the additional condition that none of the terms in the support of any  $f_i$  is divisible by  $z_j$  for  $i, j \in \{1, \ldots, s\}$  with  $i \neq j$ , we say that *F* is a **coherently** *Z***-separating tuple of Boolean polynomials** in *I*.

The connection between *Z*-separating and coherently *Z*-separating tuples of Boolean polynomials is described by the following proposition. The analogous proposition for usual polynomials can be found as Proposition 2.2.d in [\[13\]](#page-27-3).

**Proposition 6.1.** *Let I be a proper ideal in*  $\mathbb{B}_n$ *, let*  $(f_1, \ldots, f_s)$  *be a Z-separating tuple of Boolean polynomials in I*, and let  $\sigma$  be a term ordering on  $\mathbb{B}_n$  with  $LT_{\sigma}(f_i) = z_i$  for  $i=1,\ldots,s$ . Moreover, write  $f_i = z_i + h_i$  with  $h_i \in \mathbb{B}_n$ , and let  $\tilde{h}_i = \text{NR}_{\sigma,(f_1,\ldots,f_s)}(h_i)$  $for i = 1, \ldots, s$ *. Then the tuple*  $(z_1 - \tilde{h}_1, \ldots, z_s - \tilde{h}_s)$  *is a coherently Z*-separating tuple *of Boolean polynomials in I.*

*Proof.* For  $i \in \{1, \ldots, s\}$ , let  $F_i, Z_i, \widetilde{H}_i$  be the canonical representatives of  $f_i, z_i, \widetilde{h}_i$ , respectively. By the definition of the normal remainder, the polynomials  $H_i$  are fully reduced against  $F_1, \ldots, F_s$ . Thus no term in their support is divisible by any of the leading terms of  $F_1, \ldots, F_s$ . Since  $LT_{\sigma}(F_j) = Z_j$  for  $j = 1, \ldots, s$ , this implies that  $Z_j$ does not divide any of the terms in the support of  $H_i$ , and hence  $z_j$  does not divide any of the terms in the support of  $\tilde{h}_i$  for  $i, j \in \{1, \ldots, s\}$ . Consequently, none of the terms in the support of  $z_i - \tilde{h}_i$  is divisible by  $z_j$  for  $i, j \in \{1, \ldots, s\}$  with  $i \neq j$ . In addition, it is easy to see that  $h_i - \tilde{h}_i \in \langle f_1, \ldots, f_s \rangle \subseteq I$ , and so  $z_i - \tilde{h}_i = f_i - (h_i - \tilde{h}_i) \in I$  for  $i = 1, \ldots, s$ . Therefore the tuple  $(z_1 - \tilde{h}_1, \ldots, z_s - \tilde{h}_s)$  is a coherently *Z*-separating tuple of Boolean polynomials in *I*.

In order to construct separating re-embeddings of an ideal  $I$  in  $\mathbb{B}_n$ , one can apply the result below. Here a **Boolean re-embedding** of *I* is an  $\mathbb{F}_2$ -algebra isomorphism

$$
\Psi: \mathbb{B}_n/I \longrightarrow \mathbb{B}_m/I'
$$

where  $m \in \mathbb{N}$  and  $I'$  is an ideal of  $\mathbb{B}_m$ .

#### **Proposition 6.2. (Boolean** *Z***-Separating Re-Embeddings)**

*In the setting described above, let I be a proper ideal in*  $\mathbb{B}_n$ *, and let*  $\mathbb{B}_m = \mathbb{F}_2[X \setminus Z]$ *with*  $m = n - s$ *. Assume that*  $F = (f_1, \ldots, f_s)$  *is a coherently Z-separating tuple of Boolean polynomials in I* with respect to a term ordering  $\sigma$  on  $\mathbb{B}_n$ *. For*  $i = 1, \ldots, s$ *, write*  $f_i = z_i - h_i$  *with*  $h_i \in \mathbb{B}_m$ .

 $(a)$  *The reduced Boolean*  $\sigma$ -*Gröbner basis of I is of the form* 

$$
G = \{z_1 - \tilde{h}_1, \ldots, z_s - \tilde{h}_s, g_1, \ldots, g_r\},\
$$

 $where \tilde{h}_1, \ldots, \tilde{h}_s, g_1, \ldots, g_r \in \mathbb{B}_m$ .

*(b) The*  $\mathbb{F}_2$ -algebra homomorphism  $\Phi : \mathbb{B}_n / I \longrightarrow \mathbb{B}_m / (I \cap \mathbb{B}_m)$  given by

$$
\Phi(x_i + I) = \begin{cases} x_i + (I \cap \mathbb{B}_m) & \text{for } x_i \notin Z \\ h_j + (I \cap \mathbb{B}_m) & \text{for } x_i = z_j \in Z \end{cases}
$$

*is an isomorphism of*  $\mathbb{F}_2$ -algebras. It is called a **Boolean** Z-separating re*embedding of I.*

*(c) For every elimination ordering*  $\tau$  *for*  $Z$ *, we have*  $\langle Z \rangle \subseteq \mathop{\rm LT}\nolimits_{\tau}(I)$ *.* 

*Proof.* Let *G* be the reduced Boolean *σ*-Gröbner basis of *I*, and let  $\tilde{h}_i = \text{NR}_{\sigma,G}(h_i)$ for  $i = 1, ..., s$ . By assumption, we have  $z_i = LT_{\sigma}(f_i) \in LT_{\sigma}(I)$  and  $h_i \in \mathbb{B}_m$ . In particular, since  $LT_{\sigma}(I) \neq \langle 1 \rangle$ , we have  $z_i - \tilde{h}_i \in G$  and  $\tilde{h}_i \in \mathbb{B}_m$  for  $i = 1, \ldots, s$ . Thus we can write  $G = \{z_1 - \tilde{h}_1, \ldots, z_s - \tilde{h}_s, g_1, \ldots, g_r\}$ , where  $g_1, \ldots, g_r \in \mathbb{B}_n$ . Moreover, since  $G$  is a reduced Gröbner basis, we know that  $z_i$  does not divide any term in Supp $(g_i)$  for  $i \in \{1, \ldots, s\}$  and  $j \in \{1, \ldots, r\}$ . Hence we get  $g_1, \ldots, g_r \in \mathbb{B}_m$ , and claim (a) follows.

19

To show (b), it suffices to prove that  $I = \langle G \rangle$  is the kernel of the  $\mathbb{F}_2$ -algebra epimorphism  $\varphi : \mathbb{B}_n \longrightarrow \mathbb{B}_m / (I \cap \mathbb{B}_m)$  defined by  $x_i \mapsto x_i + (I \cap \mathbb{B}_m)$  for  $x_i \notin Z$  and by  $x_i \mapsto h_j + (I \cap \mathbb{B}_m)$  for  $x_i = z_j \in Z$ .

Clearly,  $G \subseteq \text{Ker}(\varphi)$ , and so  $I = \langle G \rangle \subseteq \text{Ker}(\varphi)$ . For the other inclusion, let  $h \in \text{Ker}(\varphi)$  and write  $h = \text{NR}_{\sigma,G}(h)$ . Then  $\tilde{h} \in \mathbb{B}_m$  and  $h = f + \tilde{h}$  for a Boolean polynomial  $f \in I$ . Since we already know  $I \subseteq \text{Ker}(\varphi)$ , this implies  $\varphi(\tilde{h}) = \varphi(h) = 0$ , and so  $h \in I \cap \mathbb{B}_m$ . Hence we get  $h = f + h \in I$ .

Finally, claim (c) follows from the observation that  $LT_{\tau}(f_i) = LT_{\tau}(z_i - h_i) = z_i \in$  $LT_{\tau}(I)$  for  $i = 1, ..., s$ , because  $\tau$  is an elimination ordering for *Z*.

The next proposition provides a connection between *Z*-separating Boolean polynomials and *Z*-separating polynomials in *P*.

<span id="page-19-0"></span>**Proposition 6.3.** Let  $I'$  be a proper ideal in  $P$  that contains the field ideal  $\mathbb{I}_n$ , and *let*  $I = I'/\mathbb{I}_n$ *. Let*  $Z = (z_1, \ldots, z_s)$  *be a tuple of distinct Boolean indeterminates, and let*  $Z' = (Z_1, \ldots, Z_s)$  *be the tuple of their canonical representatives, i.e., let*  $Z_i \in$  $\{X_1, \ldots, X_n\}$  and  $z_i = Z_i + \mathbb{I}_n$  for  $i = 1, \ldots, s$ *. Furthermore, let*  $F_1, \ldots, F_s \in P$  and *let*  $f_i = F_i + \mathbb{I}_n$  *for*  $i = 1, \ldots, s$ *.* 

- (a) If  $(F_1, \ldots, F_s)$  *is a Z*'-separating tuple of polynomials in *I*', then  $(f_1, \ldots, f_s)$  *is a Z-separating tuple of Boolean polynomials in I.*
- *(b)* If  $(f_1, \ldots, f_s)$  *is a Z-separating tuple in I* and  $F_1, \ldots, F_s$  are the canonical repre*sentatives of*  $f_1, \ldots, f_s$ *, respectively, then*  $(F_1, \ldots, F_s)$  *is a Z*'-separating tuple of *polynomials in I* ′ *.*
- *(c)* The tuple  $Z'$  is a separating tuple of indeterminates for  $I'$  if and only if the tuple  $Z$ *is a separating tuple of Boolean indeterminates for I.*

*Proof.* To show (a), let  $\sigma$  be a term ordering on *P* such that  $LT_{\sigma}(F_i) = Z_i$  for  $i = 1, \ldots, s$ . Fix  $i \in \{1, \ldots, s\}$ . Consider  $t = x_{i_1} \cdots x_{i_k} \in \text{Supp}(f_i) \setminus \{z_i\}$ , where  $k = \deg(t)$ . Then there are  $\alpha_1, \ldots, \alpha_k \in \mathbb{N}_+$  with  $T = X_{i_1}^{\alpha_1} \cdots X_{i_k}^{\alpha_k} \in \text{Supp}(F_i)$ . It follows from  $LT_{\sigma}(F_i) = Z_i$  that  $Z_i = LT_{\sigma}(F_i) >_{\sigma} T \geq_{\sigma} X_{i_1} \cdots X_{i_k}$ , and hence  $z_i > \sigma x_{i_1} \cdots x_{i_k} = t$ . This implies that  $LT_{\sigma}(f_i) = z_i$ . Therefore  $(f_1, \ldots, f_s)$  is a *Z*-separating tuple of Boolean polynomials in *I*.

To prove (b), let  $\sigma$  be a term ordering such that  $LT_{\sigma}(f_i) = z_i$  for  $i = 1, \ldots, s$ . Then by the definition of leading terms of Boolean polynomials, we have  $LT_{\sigma}(F_i) = Z_i$  for all  $i = 1, \ldots, s$ , and thus the tuple  $(F_1, \ldots, F_s)$  is a Z'-separating tuple of polynomials in  $I'$ .

By the definition of separating tuples of indeterminates, (c) follows immediately from  $(a)$  and  $(b)$ .  $\Box$ 

After these preparations, we are now ready to adapt our algorithms to check whether a tuple *Z* of Boolean indeterminates is a separating tuple for a given ideal in  $\mathbb{B}_n$ . The following result plays an important role for that.

<span id="page-19-1"></span>**Proposition 6.4** (Computation of *Z*-Separating Boolean Polynomials)**.**

*Let I be a proper ideal in*  $\mathbb{B}_n$ *, let*  $\{g_1, \ldots, g_r\} \subseteq \mathbb{B}_n$  *be a system of generators of I, and let*  $G_1, \ldots, G_r \in P$  *be the canonical representatives of*  $g_1, \ldots, g_r$ *. Furthermore, let*  $Z =$ 

 $(z_1, \ldots, z_s)$  be a tuple of distinct Boolean indeterminates, and let  $Z' = (Z_1, \ldots, Z_s)$ *be the tuple of their canonical representatives.*

- (a) If we apply Algorithm [3.2](#page-6-0) to the input  $(G_1, \ldots, G_r)$  and  $Z'$ , it successfully returns *a* weight tuple  $W \in \mathbb{N}^n$  if and only if there exist  $f_1, \ldots, f_s \in \langle g_1, \ldots, g_r \rangle_{\mathbb{F}_2}$  such that  $(f_1, \ldots, f_s)$  *is a Z-separating tuple of Boolean polynomials in I.*
- *(b) In the case of (a), let σ be any term ordering which is compatible with the grading given by W*. Then there exist  $f'_1, \ldots, f'_s \in \langle g_1, \ldots, g_r \rangle_{\mathbb{F}_2}$  with  $LT_{\sigma}(f'_i) = z_i$  for  $i = 1, \ldots, s$ .

*Proof.* Let  $U = \langle g_1, \ldots, g_r \rangle_{\mathbb{F}_2}$  and let  $U' = \langle G_1, \ldots, G_r \rangle_{\mathbb{F}_2}$ . Consider the  $\mathbb{F}_2$ -linear map  $\varphi : \mathbb{B}_n \to P$  that maps every Boolean polynomial to its canonical representative. Then the restriction map  $\varphi|_U: U \to U'$  is an isomorphism of  $\mathbb{F}_2$ -vector spaces. We first show that there is a *Z*-separating tuple of Boolean polynomials for *I* in *U* if and only if there is a *Z*'-separating tuple of polynomials for  $I' = \langle G_1, \ldots, G_s \rangle + \mathbb{I}_n$  in *U'*.

Suppose that  $(f_1, \ldots, f_s) \in U^s$  is a *Z*-separating tuple of Boolean polynomials for *I*. Then  $(\varphi(f_1), \ldots, \varphi(f_s)) \in (U')^s$  is a *Z*'-separating tuple for *I*' by Proposi-tion [6.3.](#page-19-0)b. Conversely, let  $(F_1, \ldots, F_s) \in (U')^s$  be a  $Z'$ -separating tuple of polynomials for *I'*, and let  $f_i = F_i + \mathbb{I}_n$  for  $i = 1, \ldots, s$ . Then  $(f_1, \ldots, f_s)$  is a *Z*-separating tuple for *I* by Proposition [6.3.](#page-19-0)a. Since  $F_1, \ldots, F_s \in U'$ , every term in their support is in the support of one of the polynomials  $G_1, \ldots, G_r$  and thus square-free. It follows that every *F*<sup>*i*</sup> is the canonical representative of *f*<sup>*i*</sup> and therefore  $f_i = \varphi^{-1}(F_i) \in \varphi^{-1}(U') = U$  for  $i = 1, \ldots, s.$ 

In Proposition [3.3](#page-7-0) it was shown that Algorithm [3.2](#page-6-0) successfully returns a weight tuple *W* if and only if there exists a  $Z'$ -separating tuple of polynomials in  $U'$ . By the observation above, this is equivalent to the condition that there exists a *Z*-separating tuple of polynomials for *I* in *U*. This shows (a).

For (b), let  $\sigma$  be a term ordering which is compatible with the grading given by *W*. By Algorithm [3.2](#page-6-0) and Proposition [3.3,](#page-7-0) there exists a  $Z'$ -separating tuple  $(F'_1, \ldots, F'_s)$ in *U*' such that  $LT_{\sigma}(F_i') = Z_i$  for  $i = 1, ..., s$ . The canonical representative of the element  $f'_i = F'_i + \mathbb{I}_n$  is  $F'_i$  for  $i = 1, \ldots, s$ . Therefore we conclude that  $LT_{\sigma}(f'_i)$  $LT_{\sigma}(F'_{i}) + I_{n} = z_{i}$  for  $i = 1, ..., s$ .  $\Box$ 

**Remark 6.5.** Let  $Z = (z_1, \ldots, z_s)$  be a tuple of distinct Boolean indeterminates in *X*, let  $g_1, \ldots, g_r \in \mathbb{B}_n$ , and let  $Z_i, G_j$  be the canonical representatives of  $z_i, g_j$ , respectively, where  $i \in \{1, \ldots, s\}$  and  $j \in \{1, \ldots, r\}$ . The following methods can be applied to check whether *Z* is a separating tuple for the ideal  $I = \langle q_1, \ldots, q_r \rangle$ .

- (a) Apply Algorithm [3.2](#page-6-0) to  $G_1, \ldots, G_r$ . By Proposition [6.4.](#page-19-1)a, Algorithm 3.2 successfully returns a weight tuple if and only if *Z* is a separating tuple of Boolean indeterminates for *I* and there is a *Z*-separating tuple of polynomials for *I* in  $\langle g_1, \ldots, g_r \rangle_K$ .
- (b) Suppose that Algorithm [3.2](#page-6-0) successfully returns a weight tuple  $W \in \mathbb{N}^n$ , and let  $\sigma$ be a term ordering which is compatible with the grading given by *W*. Apply Algo-rithm [5.1](#page-14-2) to  $(G_1, \ldots, G_r)$  and  $(Z_1, \ldots, Z_s)$  to obtain polynomials  $F_1, \ldots, F_s \in P$ . Then we have  $F_1, \ldots, F_s \in \langle G_1, \ldots, G_r \rangle_{\mathbb{F}_2}$  with  $LT_{\sigma}(F_i) = Z_i$  for  $i = 1, \ldots, s$ .

Since all terms in the supports of  $G_1, \ldots, G_r$  are square-free, all terms in the supports of  $F_1, \ldots, F_s$  are also square-free. Thus  $F_i$  is the canonical representative of  $f_i = F_i + \mathbb{I}_n$ , and hence  $LT_{\sigma}(f_i) = LT_{\sigma}(F_i) + \mathbb{I}_n = z_i$ . This implies that  $(f_1, \ldots, f_s)$ is a *Z*-separating tuple of Boolean polynomials for *I*.

- (c) Let  $\{H_1, \ldots, H_n\}$  be a set of generators of  $\mathbb{I}_n$ , let  $I' = \langle G_1, \ldots, G_r \rangle + \mathbb{I}_n$ , and let  $Z' =$  $(Z_1, \ldots, Z_s)$ . According to Proposition [6.3.](#page-19-0)c, if Algorithm [4.1](#page-11-1) applied to  $G_1, \ldots, G_r$ ,  $H_1, \ldots, H_n$  and *Z*<sup>*'*</sup> verifies that *Z'* is a separating tuple of indeterminates for *I'*, then the tuple *Z* is a separating tuple of Boolean indeterminates for *I*. In this case, a Z'-separating tuple  $(F_1, \ldots, F_s)$  of polynomials in  $I'$  can be computed by using Remark [5.3.](#page-15-0) Then Proposition [6.3.](#page-19-0)a yields that  $(f_1, \ldots, f_s)$ , where  $f_i = F_i + \mathbb{I}_n$  for  $i = 1, \ldots, s$ , is a *Z*-separating tuple of polynomials in *I*.
- (d) Suppose that there exist  $j \in \{1, ..., r\}$  and  $i \in \{1, ..., s\}$  such that  $g_j \in I$  has no constant term and  $z_i \in \text{Supp}(g_j)$ . Then the linear part of  $z_i g_j$  is  $z_i$ . In some cases, it may be useful to add those polynomials  $z_i g_j$  to the generators of the ideal to find separating tuples of Boolean indeterminates.

### <span id="page-21-0"></span>**7 Application to the Cryptoanalysis of AES-128**

The Advanced Encryption Standard (AES) was certified by the U.S. National Institute of Standards and Technology (NIST) in 2001 (see [\[19\]](#page-27-10)) and is one of the most widely used symmetric encryption ciphers. In this section we apply our algorithms to polynomial equations describing AES-128 with the goal of improving algebraic attacks. We assume that the reader is familiar with the basic definition of AES, for instance as laid out in [\[19\]](#page-27-10).

<span id="page-21-1"></span>**Example 7.1** (Polynomial Representation of the AES *S*-Box)**.**

The only nonlinear part during the encryption process of AES-128 is the application of the Rijndael *S*-Box. This is a map  $s : \mathbb{F}_2^8 \to \mathbb{F}_2^8$  which is detailed in Section 5.1.1 of [\[19\]](#page-27-10). We describe *s* by the vanishing ideal  $I<sub>S</sub>$  of its graph, i.e., by the ideal  $I<sub>S</sub>$  in  $\mathbb{B}_{16}$ in the Boolean indeterminates  $x_1, \ldots, x_8, y_1, \ldots, y_8$  which is the vanishing ideal of the set  $S = \{(a, s(a)) \mid a \in \mathbb{F}_2^8\} \subseteq \mathbb{F}_2^{16}$ .

- (a) Using a computer algebra system such as CoCoA-5 (see [\[1\]](#page-26-0)), we can start from the 256 points of *S* and use them to compute a generating set of *IS*. In our case we used the function IdealOfPoints of CoCoA-5, which resulted in a set of 39 quadratic Boolean polynomials. We reference this set as  $G_{\text{std}}$  for the remaining part of this section.
- (b) Now we apply our implementation of Algorithm [3.2](#page-6-0) in the computer algebra system SageMath (see [\[21\]](#page-27-6)) to the polynomials in  $G_{std}$  and every  $Z \subseteq \{x_1, \ldots, x_8\}$ . The result is that Algorithm [3.2](#page-6-0) is successful for every *Z* with  $#Z \leq 3$ . We choose  $Z' = (x_1, x_2, x_3)$  and use Algorithm [5.1](#page-14-2) to compute a  $Z'$ -separating tuple  $G_{123}$ . The polynomials in *G*<sup>123</sup> are of degree 2.
- (c) Proceeding as in (b), we also apply our implementation of Algorithm [4.1](#page-11-1) to  $G_{\text{std}}$ and every  $Z \subseteq \{x_1, \ldots, x_8\}$ . It turns out to be successful for every tuple Z with  $#Z \leq 6$ . We choose  $Z'' = (x_1, x_2, x_3, x_4, x_5, x_6)$  and use Remark [5.3](#page-15-0) to compute a  $Z''$ -separating tuple  $G_{1-6}$  in  $I_S$ . The polynomials in  $G_{1-6}$  are of degree 3.

- (d) If we strive to find a separating system of generators of *I<sup>S</sup>* consisting of polynomials of lowest possible degree, we can take the three polynomials of degree 2 in  $G_{123}$ , three polynomials of degree 3 in  $G_{1-6}$ , and two polynomials of degrees 5 and 7, respectively, found using further rounds of Algorithm [4.1](#page-11-1) or suitable elimination computations. The resulting tuple  $G_{1-8}$  is separating for  $(x_1, \ldots, x_8)$  and generates *IS*.
- (e) Finally we can compute a lex-Gröbner basis of  $I<sub>S</sub>$  and get a  $(x_1, \ldots, x_8)$ -separating tuple *Glex* of polynomials of degree 7.

The sets  $G_{\text{std}}, G_{\text{std}} \cup G_{123}, G_{\text{std}} \cup G_{1-6}, G_{1-8}$  and  $G_{lex}$  generate  $I_S$  and allow us to eliminate 0, 3, 6, 8, and 8 Boolean indeterminates, respectively, from *IS*. To perform the experiments below, we have to convert these Boolean polynomials to a suitable input for the solvers we consider. While Bosphorus and PolyBoRi work directly with algebraic normal forms and do not require any conversions, the solver Kissat needs CNF (conjunctive normal form) input, the solver CryptoMiniSat expects CNF-XOR, and the solver 2-Xornado uses XNF (xor-or-and normal form) formulas. Let us briefly collect the numbers of logical variables and clauses produced by the conversion tools described in [\[2\]](#page-26-4).

**Table 1** Logic Conversions

Generating set of $I_S$	$\#$ variables/clauses		
	<b>CNF</b>	CNF-XOR	<b>XNF</b>
$G_{\mathrm{std}}$	780/8722	256/519	136/399
$G_{lex}$	1062/6488	843/1424	555/1136
$G_{1-8}$	542/4061	346/606	213/473

Numbers of logical variables and clauses for the conversions of different systems of generators of *IS*.

Of course, it does not make sense to include the numbers for  $G_{\text{std}} \cup G_{123}$  and  $G_{\text{std}} \cup G_{1-6}$  since these systems of generators properly contain  $G_{\text{std}}$ . In all three cases, the conversion of  $G_{lex}$  is the least efficient one, while most of the numbers for  $G_{std}$ and  $G_{1-8}$  are similar. However, the number of CNF clauses for  $G_{std}$  is large, because the conversion process creates long linear forms which blow up the CNF. An adjusted splitting technique (see [\[10\]](#page-27-11)) could possibly improve this to some extent.

The question studied below is whether adding the polynomials in  $G_{123}$  and  $G_{1-6}$ speeds up algebraic attacks on AES-128. Let us describe the mathematical setting of general algebraic attacks first.

#### **Remark 7.2** (Algebraic Attacks on *r*-AES-128)**.**

The original cipher AES-128 is specified to have 10 rounds. For  $r \in \{1, \ldots, 10\}$ , we denote by *r*-AES-128 the version of AES-128 with *r* instead of 10 rounds, i.e., the number Nr in Figure 5 of [\[19\]](#page-27-10) is set to *r*.

Consider the ring of Boolean polynomials  $\mathbb{B}_n$  where  $n = 128 \cdot (4r + 3)$  whose indeterminates are  $k_i$ ,  $p_i$ ,  $c_i$ ,  $rk_{j,i}$ ,  $si_{j,i}$ ,  $so_{j,i}$ , and  $rk_{j,i}$  for  $i = 1, ..., 128$  and

 $j = 1, \ldots, r$ . Here the indeterminates  $\mathbf{k}_i$ ,  $\mathbf{p}_i$ ,  $\mathbf{c}_i$ , and  $\mathbf{rk}_{j,i}$  represent key, plaintext, ciphertext, and round key bits, respectively. The indeterminates  $s_{i,j,i}$  and  $s_{i,j,i}$  are additional variables for the inputs and outputs of the Subbytes transformations (see Section 5.1.1 in [\[19\]](#page-27-10)) during the encryption process (see Figure 5 in [\[19\]](#page-27-10)). Lastly, the inderterminates  $\text{rk}_i$  are additional variables for the outputs of the Subbytes transformations during the computation of the round keys (see Figure 11 in [\[19\]](#page-27-10)).

Let  $I_r \subseteq \mathbb{B}_n$  be the ideal modelling *r*-AES-128. In other words, a tuple  $(k, p, c, rk, si, so, rks) \in (\mathbb{F}_2^{128})^3 \times (\mathbb{F}_2^{128r})^4$  is a zero of  $I_r$  if and only if p encrypted with *r*-AES-128 using the key k yields c, and during the encryption process, the round keys are rk, the *S*-box inputs and outputs are si and so, respectively, and the outputs of the *S*-boxes during the round key computations are given by rks. Using a generating set  $G$  for  $I_S$  as in Example [7.1,](#page-21-1) it is now possible to construct a generating set  $H$  of  $I_r$  that only contains linear polynomials and polynomials from  $G$  with their indeterminates substituted by the corresponding input and output indeterminates of the Subbytes steps.

The purpose of the next example is to verify that known-plaintext attacks on AES-128 based on finding the zeros of a specialization of the ideal *I<sup>r</sup>* constructed in the preceding remark become easier if we enlarge the sets of generators by  $G_{123}$  or  $G_{1-6}$ to eliminate some indeterminates in the *S*-boxes. Currently, the most efficient tools to solve such systems are SAT solvers. In [\[2\]](#page-26-4) it is described how systems of Boolean polynomials can be converted to XNF (xor-or-and normal form), to XOR-CNF, and to CNF such that they become suitable inputs for current SAT solvers.

#### <span id="page-23-0"></span>**Example 7.3** (Attacking One Round of AES-128)**.**

For the following experiments, we generated Boolean polynomial systems *H* representing 1-AES-128. In order to use them to perform a known-plaintext attack, we proceeded as follows.

- (a) First we constructed a plaintext-ciphertext pair  $(p, c) \in \mathbb{F}_2^{256}$  for 1-AES-128, where  $p = (p_1, \ldots, p_{128})$  and  $c = (c_1, \ldots, c_{128})$ .
- (b) Then we specialized various systems of generators  $H$  of the ideal  $I_1$  defining the cipher by letting  $p_i \mapsto p_i$  and  $c_i \mapsto c_i$  for  $i = 1, \ldots, 128$ . Here the various systems *H* differ by the system of generators *G* which is used to represent the *S*-box.
- (c) Next we transformed the specializations to suitable inputs for state-of-the-art Boolean system solvers.
- (d) Finally, we used these solvers to determine the unknown key bits  $k_i$  in 100 randomly generated instances and measured their average solving time.

In Table [2,](#page-24-1) we compare the running times of the XOR-CNF SAT solver Crypto-MiniSat, the CNF SAT solver Kissat (see [\[7\]](#page-26-5)), and the Boolean polynomial solver Bosphorus (see [\[8\]](#page-27-12)). For CryptoMiniSat and Kissat, we converted the Boolean polynomial systems *H* to XOR-CNF and CNF, respectively, using the methods described in [\[2\]](#page-26-4).

As can be seen from this table, the Boolean polynomial system solver Bosphorus is significantly slower than the SAT solvers and is not effected much by the choice of the generating set of *IS*. Both CryptoMiniSat and Kissat profit substantially from

<span id="page-24-1"></span>**Table 2** Experiments

Generating set of $I_S$	Average solving time		
	CryptoMiniSat	Kissat	Bosphorus
$G_{std}$	$40.23$ s	$50.53$ s	244.74 s
$G_{123}\cup G_{\rm std}$	$35.69$ s	27.36 s	$257.01$ s
$G_{1-6}\cup G_{\mathrm{std}}$	21.47 s	$33.57$ s	252.78 s

Average solving times for 100 polynomial systems coming from known-plaintext attacks on one round of AES-128.

the addition of the separating tuples of polynomials  $G_{123}$  and  $G_{1-6}$ . More precisely, CryptoMiniSat performs best when using  $G_{1-6} \cup G_{\text{std}}$  and Kissat performs best when using  $G_{123} \cup G_{\text{std}}$  instead of  $G_{\text{std}}$ .

These Boolean polynomial systems were also given to the algebraic solver PolyBoRi (see [\[7\]](#page-26-5)) and to the XNF-solver 2-Xornado (see [\[2\]](#page-26-4)). However, neither of these solvers terminated on any of the instances in under one hour.

For our next experiment, we considered 2-AES-128 and assumed that a certain amount of bits of the secret key was known, as happens for instance in the case of some sidechannel attacks or for some types of guess-and-determine attacks.

#### <span id="page-24-0"></span>**Example 7.4** (Attacking Two Rounds of AES-128)**.**

For this experiment, we created 220 instance of algebraic attacks to 2-AES-128. As above, we substituted randomly generated known plaintext-ciphertext pairs into the Boolean polynomials. Then we constructed 20 instances for each value  $k \in$ {70*, . . . ,* 80}, where we assume that we know the first *k* bits of the secret key. These values were also chosen randomly and substituted into the equations.

In the following cactus plot, we draw the solving times that Bosphorus and CryptoMiniSat needed for several systems of generators *H* of 2-AES-128 derived from the stated systems of generators  $G$  of the vanishing ideal  $I<sub>S</sub>$  of the S-boxes.

**Fig. 1** Running times of {solver} {gens} for 220 satisfiable instances related to key-recovery attacks on 2-AES-128 with knowledge of the first  $70 \leq k \leq 80$  key bits.

As one can see, the Boolean polynomial system based on the polynomials *G*1−<sup>8</sup> constructed using Algorithms [3.2](#page-6-0) and [4.1](#page-11-1) is solved significantly faster by CryptoMiniSat (denoted by CMS5) than the system based on the original generators  $G_{\text{std}}$ . The solver Bosphorus did not terminate on the instances involving  $G_{lex}$  and  $G_{1-8}$ .

All experiments in this section were performed on an AMD Ryzen 5 7530U CPU with 16 GB of RAM under Manjaro Linux. We used CryptoMiniSat version 5.11.22, Kissat version 4.0.1, and Bosphorus version 3.0.0.

### **Conclusion**

In recent years, a new technique for performing elimination on large-scale examples of polynomial ideals has emerged. It has been called elimination by substitution or the method of *Z*-separating re-embeddings. In this paper we made another important step in the development of this technique. Previous works discussed fast ways of finding tuples of indeterminates *Z* which are candidates for this type of elimination computation [\[13,](#page-27-3) [14,](#page-27-1) [17\]](#page-27-2). Frequently there is a large number of such candidate tuples. Here we provide several algorithms which allow us to check quickly whether a given tuple  $Z = (z_1, \ldots, z_s)$  is suitable.

In other words, given an ideal *I* in a polynomial ring  $K[X] = K[x_1, \ldots, x_n]$ , we want to test whether  $I \cap K[X \setminus Z]$  can be computed using elimination by substitution. For this, we want to check whether polynomials of the form  $f_i = z_i - h_i$  exist in *I*, where  $h_i$  is not divisible by any indeterminate in  $Z$ . In full generality, this would require the calculation of a Gröbner basis of  $I$  which is infeasible in many cases. Therefore we search for the polynomials  $f_i$  in suitable subspaces of  $I$ .

The algorithms we develop are very fast and allow us to treat examples with dozens, even hundreds of indeterminates. The main idea is not to look for the polynomials *f<sup>i</sup>* directly, but for a tuple of weights *W* such that, for any term ordering  $\sigma$  compatible with the grading given by *W*, there exist polynomials  $f_i \in I$  with  $LT_{\sigma}(f_i) = z_i$ . Having found *W*, the actual polynomials defining the *Z*-separating re-embedding can then be calculated by simple interreduction.

Applications include examples of ideals for which traditional methods of elimination computation fail, such as ideals defining border basis schemes in Algebraic Geometry. Another area which may benefit from the new techniques is Cryptography. To apply the new method in this case, we developed a variant which is able to perform elimination by substitution for Boolean polynomials. For example, we show how *Z*-separating Boolean polynomials speed up several types of algebraic attacks on the cipher AES-128.
