

The behavioral approach for LPV data-driven representations

Chris Verhoek, Ivan Markovsky, Sofie Haesaert, and Roland Toth ´

*Abstract***— In this paper, we present data-driven representations of** *linear parameter-varying* **(LPV) systems that can be used for direct data-driven analysis and control of LPV systems. Specifically, we use the behavioral approach for LPV systems to develop a data-driven representation of the finite-horizon behavior of an LPV system that can be represented by a kernel representation with** *shifted-affine* **scheduling dependence. Moreover, we provide a necessary and sufficient rank-based test on the available data that concludes whether the data-driven representation** *fully* **represents the finite-horizon behavior. The results in this paper allow for direct data-driven analysis and control of LPV systems with stability and performance guarantees. We demonstrate this by also solving the LPV data-driven simulation problem. Moreover, through the use of LPV systems as surrogates for nonlinear systems, our results may serve as a stepping stone towards direct data-driven analysis and control of nonlinear systems.**

*Index Terms***— Behavioral systems theory, linear parameter-varying systems, data-driven simulation and control.**

I. INTRODUCTION

The ever-growing complexity of engineering systems, together with the increasing amount of available data, makes that there is a growing interest in analysis and control design methods that are directly based on data. Particularly, direct data-driven analysis and control methods that are based on the behavioral framework have gained a lot of attention, because these methods allow to give rigorous stability and performance guarantees, purely based on data. A key result in direct data-driven analysis and control is Willems' Fundamental Lemma [1], which allows to represent the behavior of a *discrete-time* (DT) *linear time-invariant* (LTI) system using a single sequence of measurement data, where the data is *persistently exciting* (PE), i.e., the data is sufficiently 'rich'. Based on this result, many data-driven analysis and

Corresponding author: Chris Verhoek. control methods have been developed for DT LTI systems, see, e.g., [2] for an overview.

Many extensions of the Fundamental Lemma have been proposed in the literature, such as a variant for *continuoustime* (CT) LTI systems [3], 2D LTI systems [4], an extension for stochastic LTI systems [5], and representations of convex, conical and affine behaviors [6]. Beyond the class of LTI systems, there are several approaches that aim to extend the Fundamental Lemma towards (specific classes of) nonlinear systems, e.g., [7]–[10]. These methods, however, generally impose restrictive assumptions on the system (the system must be feedback linearizable, periodic or described by a Volterra series). These assumptions make that the problem can be recasted as an LTI system on which Willems' Fundamental Lemma is applied. In this paper, we consider the extension of the Fundamental Lemma for *linear parameter-varying* (LPV) systems.

LPV systems are linear systems for which the behavior is defined by a linear relationship that depends on a *measurable* signal p, called the *scheduling signal*. The LPV framework is often used to provide linear, surrogate models for the analysis and control of nonlinear systems, where the scheduling signal captures the nonlinearities and exogenous effects [11], [12]. This makes the LPV framework a bridge between linear and nonlinear analysis and control. Developing direct data-driven analysis and control methods for LPV systems is therefore an important stepping stone to achieve a generalization of the original data-driven results to the nonlinear case.

In this paper, we consider LPV systems that can be represented by an LPV *input-output* (IO) representation with *shifted-affine* scheduling dependence, which we refer to as LPV-SA systems. This is a highly useful subclass of LPV systems, as it admits a direct LPV *state-space* (SS) representation with static dependence, which is convenient for usage in LPV analysis and control methods. Moreover, through the fundamental theorem of calculus, a large class of nonlinear systems can be modeled as LPV-SA systems [13], [14]. In [15], a rather general formulation of the LPV extension of the Fundamental Lemma was given for the class of LPV systems with a meromorphic, dynamic scheduling dependence. This formulation, however, results in a data-driven representation that is constructed from meromorphic composition weights, which are hard to be used in practice. It was also shown as a remark in [15], that this general form of the LPV Fundamental Lemma can be reduced to a simpler, practically useful form for LPV-SA systems, based on which a whole series of contributions on data-driven LPV methods have been developed [16]–[20]. However, the Fundamental Lemma for this rather useful subclass of LPV-SA systems has never been directly formulated. Furthermore, the corresponding conditions to check whether the data is 'rich' enough, i.e., PE, were never sorted out. Moreover, the LPV data-driven simulation problem has not been formally solved yet. In this paper, we fill these gaps in the current literature. That is, we formulate a data-driven LPV representation for LPV-SA systems that is directly computable from data, with accompanying necessary and sufficient conditions to conclude whether the data is PE. More specifically, the contributions of this work are:

- C1: We formulate a finite-horizon data-driven LPV representation for LPV-SA systems that is computable from a given data-set;
- C2: We provide a necessary and sufficient condition that is verifiable from the given data-set, to conclude whether the data can characterize the full finite-horizon behavior of the LPV-SA system;
- C3: We provide a formal solution to the data-driven simulation problem.

The remainder of the paper is structured as follows. We formalize the problem in Section [II.](#page-1-0) Section [III](#page-2-0) discusses the properties of behaviors of LPV-SA systems, such as their complexity and dimension. The data-driven representation and associated conditions on the data, constituting to Contributions [C1](#page-1-1) and [C2,](#page-1-2) are given in Section [IV.](#page-3-0) The formalization of the simulation problem and its solution (Contribution [C3\)](#page-1-3), together with an accompanying example is given in Section [V.](#page-6-0) The conclusions and possible future research directions are given in Section [VI.](#page-7-0)

Notation:

 $\mathbb R$ is the set of real numbers, while the set of integers is given by $\mathbb Z$. Consider the subspaces $\mathbb A, \mathbb B$. The projection of $\mathbb{D} \subseteq \mathbb{A} \times \mathbb{B}$ onto the elements of A is denoted by $\pi_a \mathbb{D} =$ ${a \in A \mid (a, b) \in \mathbb{D}}$, while $\mathbb{B}^{\mathbb{A}}$ indicates the collection of all maps from A to B. We denote the dimension of a subspace by dim(A). The p-norm of a vector $x \in \mathbb{R}^{n_x}$ is denoted by $||x||_p$. For the two matrices $A \in \mathbb{R}^{n \times m}$ and $B \in$ $\mathbb{R}^{p \times q}$, the Kronecker product is given as $A \otimes B \in \mathbb{R}^{pm \times qn}$, while blkdiag is the block-diagonal operator for matrices, i.e., blkdiag $(A, B) = \begin{bmatrix} A & 0 \\ 0 & B \end{bmatrix} \in \mathbb{R}^{n+p \times m+q}$. The identity matrix of size $n \times n$ is denoted as I_n . Furthermore, $col(x_1, \ldots, x_n)$ denotes the column vector $\begin{bmatrix} x_1^{\top} & \cdots & x_n^{\top} \end{bmatrix}^{\top}$. Consider a signal $w : \mathbb{Z} \to \mathbb{R}^{n_w}$. The value of a signal $w : \mathbb{Z} \to \mathbb{R}^{n_w}$ at time step k is denoted as $w(k) \in \mathbb{R}^{n_w}$, and its ith element at time step k is denotes as $w_i(k) \in \mathbb{R}$. The forward and backward time-shift operators are denoted by q and q^{-1} . We denote a time-interval between $k = t_1$ and $k = t_2, t_1 \leq t_2$ by $[t_1, t_2] \subset \mathbb{Z}$. For the time interval $\mathbb{T} \subseteq \mathbb{Z}$, we write $w_{\mathbb{T}}$ as the truncation to w on \mathbb{T} , e.g., for $\mathbb{T} := [1, N]$ we have $w_{[1,N]} = (w(1), \ldots, w(N)) \in (\mathbb{R}^{n_w})^{[1,N]}$. The notation $w \wedge v$ indicates concatenation of the signals w and $v \in (\mathbb{R}^{n_v})^{\mathbb{Z}}$, while, with a slight abuse of notation, $col(w, v)$ indicates the stacked signal $\left(\ldots, \begin{bmatrix} w(k-1) \\ v(k-1) \end{bmatrix}, \begin{bmatrix} w(k) \\ v(k) \end{bmatrix}\right)$ $\left[\begin{smallmatrix} w(k)\ v(k) \end{smallmatrix}\right], \left[\begin{smallmatrix} w(k+1)\ v(k+1) \end{smallmatrix}\right], \ldots$). A sequence of the following form $(p(\overline{k}) \otimes w(\overline{k}))_{k=1}^N$ is denoted

by w_{F}^{p} $_{[1,N]}^{\text{p}}$. For $w_{[1,N]}$, the associated Hankel matrix of depth L is given by

$$
\mathcal{H}_L(w_{[1,N]}) = \begin{bmatrix} w(1) & w(2) & \dots & w(N-L+1) \\ w(2) & w(3) & \dots & w(N-L+2) \\ \vdots & \vdots & \ddots & \vdots \\ w(L) & w(L+1) & \dots & w(N) \end{bmatrix},
$$

while the block-diagonal Kronecker operator '⊚' is denoted as $w_{[1,N]} \odot I_n = \text{blkdiag}(w(1) \otimes I_n, \ldots, w(N) \otimes I_n).$

II. PROBLEM FORMULATION

A. System definition and behaviors

We study DT LPV systems that can be represented by the *kernel* representation:

$$
\underbrace{\sum_{i=0}^{n_r} r_i(q^i p) q^i}_{R(p,q)} w = 0, \tag{1a}
$$

with manifest signals $w \in (\mathbb{R}^{n_w})^{\mathbb{Z}}$, scheduling signals $p \in \mathbb{P}^{\mathbb{Z}}$ and scheduling dependent coefficients $r_i: \mathbb{P}^{\mathbb{Z}} \to \mathbb{R}^{n_k \times n_w}$ that have a *shifted-affine* dependence on p:

$$
r_i(\mathbf{q}^i p) = r_{i,0} + \sum_{j=1}^{n_p} r_{i,j} \mathbf{q}^i p_j.
$$
 (1b)

Therefore, we refer to LPV systems that are governed by [\(1\)](#page-1-4) as *LPV Shifted-Affine* (LPV-SA) systems. The signal p is varying in the *scheduling set* $\mathbb{P} \subseteq \mathbb{R}^{n_p}$, which is often a closed subset of $\mathbb{R}^{n_{\rm p}}$ that contains the origin. We want to emphasize here that a kernel representation can be viewed as a compact IO representation, where $w = col(u, y)$ and $r_i = [r_{u,i} \ r_{v,i}]$. These relations will also be made more concrete in Section [III.](#page-2-0) Let us for the remainder of this paper denote the class of LPV-SA systems with $n_{\rm p}$ scheduling signals and $n_{\rm w}$ manifest variables by $\Sigma_{n_{\rm p},n_{\rm w}}$.

In this paper, we consider the *behavioral approach*. The behavior $\mathfrak B$ is the collection of all solution trajectories compatible with the system. The representation [\(1\)](#page-1-4) is a representation of a given behavior $\mathfrak B$ of an LPV-SA system if

$$
\mathfrak{B} = \{ (w, p) \in (\mathbb{R}^{n_w} \times \mathbb{P})^{\mathbb{Z}} \mid (1) \text{ holds} \}. \tag{2}
$$

We refer to [\(1\)](#page-1-4) being minimal if both n_r and n_k are the smallest among all possible kernel representations that can characterize \mathfrak{B} of a $\Sigma \in \Sigma_{n_{\text{p}},n_{\text{w}}}$, i.e., the schedulingdependent matrix polynomial $R(p, q)$ in [\(1\)](#page-1-4) has full row rank with rank n_k and highest polynomial degree n_r .

A few subsets of $\mathfrak B$ are useful to consider. The set of admissible scheduling trajectories of B is called the *projected scheduling behavior*:

$$
\mathfrak{B}_{\mathbb{P}} = \pi_{p} \mathfrak{B} = \{ p \in \mathbb{P}^{\mathbb{Z}} \mid \exists w \in (\mathbb{R}^{n_{w}})^{\mathbb{T}} \text{ s.t. } (w, p) \in \mathfrak{B} \}. \tag{3}
$$

The set of w trajectories that are compatible with a given, fixed^{[1](#page-1-5)} scheduling trajectory $p \in \mathfrak{B}_{\mathbb{P}}$, i.e.,

$$
\mathfrak{B}_p = \{ w \in (\mathbb{R}^{n_w})^{\mathbb{T}} \mid (w, p) \in \mathfrak{B} \}. \tag{4}
$$

¹By fixed we do *not* mean $p(k) \equiv c$ for all k, $c \in \mathbb{R}^{n_p}$, but a single p trajectory from $\mathfrak{B}_{\mathbb{P}}$.

Because LPV systems are linear along a scheduling trajectory, \mathfrak{B}_p is a linear subspace. LPV systems are time invariant in the sense that $q\mathfrak{B} = \mathfrak{B}$, and thus $q\mathfrak{B}_p = \mathfrak{B}_{qp}$.

We will also consider trajectories of the system that are restricted to the time interval $[k_1, k_2] \subset \mathbb{Z}, k_1 \leq k_2$. The set containing these trajectories is given by

$$
\mathfrak{B}|_{[k_1,k_2]} = \{ (w,p)_{[k_1,k_2]} \in (\mathbb{R}^{n_w} \times \mathbb{P})^{[k_1,k_2]} \mid
$$

\n
$$
\exists (\omega,\rho) \in \mathfrak{B} \text{ s.t. } (w(k),p(k)) = (\omega(k),\rho(k))
$$

\nfor $k_1 \le k \le k_2$.

Note that this notation can be applied to the projected behaviors as well, and, due to time-invariance of LPV systems, $\mathfrak{B}|_{[k_1,k_2]} = \mathfrak{B}|_{[1,k_2-k_1+1]}.$

B. Problem statement

The goal of this paper is to characterize $\mathfrak{B}|_{[1,L]}$ purely based on a given data-set (Contribution [C1\)](#page-1-1). It is important that the characterization is *computable* and that it is verifiable from data whether the full $\mathfrak{B}|_{[1,L]}$ is represented by the data (Contribution [C2\)](#page-1-2). Once we have these, we can use the representation for data-driven simulation (Contribution [C3\)](#page-1-3). This gives the following problem formulations:

Problem 1. Given a data-set^{[2](#page-2-1)} from an LPV-SA system $\Sigma \in$ $\Sigma_{n_{\rm n},n_{\rm w}}$ with behavior \mathfrak{B} and a given complexity:

$$
\mathcal{D}_{N_{\rm d}} = (\breve{w}_{[1,N_{\rm d}]}, \breve{p}_{[1,N_{\rm d}]}) \in \mathfrak{B}|_{[1,N_{\rm d}]},\tag{5}
$$

where \check{w} and \check{p} are noise free. With the user-defined parameter L, formulate a data-based representation for $\mathfrak{B}|_{[1,L]}$ of $\check{\Sigma}$ using only \mathcal{D}_{N_d} .

For efficient formulation, we require conditions on the dataset that allow to conclude whether \mathcal{D}_{N_d} is 'rich' enough to represent $\mathfrak{B}|_{[1,L]}$:

Problem 2. Give an explicit condition that is verifiable from \mathcal{D}_{N_d} that concludes whether $\mathfrak{B}|_{[1,L]}$ of $\check{\Sigma}$ can be fully represented by $\mathcal{D}_{N_{\rm d}}$.

As motivated in Section [I,](#page-0-0) the data-driven simulation problem for LPV systems was not formally solved. In this paper, we fill this gap by solving the following problem:

Problem 3. Use the solutions to Problems [1](#page-2-2) and [2](#page-2-3) to achieve data-driven simulation of $\check{\Sigma}$ based on \mathcal{D}_{N_d} .

In this paper, we solve these problems in terms of deriving a data-driven representation of Σ on the horizon [1, L], providing a necessary and sufficient rank-based condition on \mathcal{D}_{N_d} to show that this representation fully represents $\mathfrak{B}|_{[1,L]}$, and formulating an algorithm to use the representation for simulation in a fully data-based setting. To obtain the solutions to the above problems, we first need to study the properties of LPV-SA systems and their (restricted) behaviors.

III. PROPERTIES OF LPV-SA BEHAVIORS

In this section, we provide the properties of LPV-SA behaviors that are instrumental to solve Problems [1–](#page-2-2)[3.](#page-2-4) We first provide the connections between kernel, IO and SS representations of LPV-SA behaviors. These connections naturally lead to the formal notion of complexity for an LPV-SA system, with which we formulate one of the key ingredients required to solve Problem [2;](#page-2-3) the dimension of $\mathfrak{B}_p|_{[1,L]}.$

A. Representations of LPV-SA behaviors

As motivated in Section [I,](#page-0-0) the class of LPV-SA systems is, although restrictive, a highly useful system class. This is because it has direct IO and SS realizations with a structured dependence, which streamline LPV identification, analysis and control design.

1) Input-output representations: A key aspect of the behavioral framework is that there is no prior distinction between inputs and outputs. This makes that kernel representations, e.g., [\(1\)](#page-1-4), are the fundamental building blocks for representing systems in this framework. In control engineering, however, defining input and output properties of signals is often needed. In this paper, we consider the partitioning^{[3](#page-2-5)} $w = col(u, y)$, with $u : \mathbb{Z} \to \mathbb{R}^{n_u}$ the input and $y : \mathbb{Z} \to \mathbb{R}^{n_y}$ the output signal and $n_w = n_u + n_v$. If the input is chosen such that it is *maximally free*^{[4](#page-2-6)}, the number of inputs n_u is an invariant property of \mathfrak{B} . We denote this property by $\mathbf{m}(\mathfrak{B})$, and this is in fact the first component of the *complexity* of B. Splitting up [\(1\)](#page-1-4) according to the aforementioned partitioning such that $r_i(p, q) = [b_i(p, q) - a_i(p, q)]$, where

$$
a(p,q) = \sum_{i=0}^{n_a} a_i (q^{-i}p) q^{-i}, \quad b(p,q) = \sum_{i=0}^{n_b} b_i (q^{-i}p) q^{-i}, \tag{6}
$$

with $n_r = \max(n_a, n_b)$, gives the shifted-affine LPV-IO realization

$$
y(k) + \sum_{i=1}^{n_a} a_i(p(k-i))y(k-i) = \sum_{j=0}^{n_b} b_j(p(k-j))u(k-j). \tag{7}
$$

As the scheduling-dependent functions a_i, b_i are simply partitions of the coefficient functions r_i in [\(1\)](#page-1-4), they are affine in $p(k - i)$. We have taken the a polynomial here to be monic, without loss of generality. Minimality of the LPV-IO representation [\(7\)](#page-2-7) is directly adopted from the kernel representation, and is achieved if a has n_v rows, and the polynomials a and b are *left-coprime* [11]. The latter implies that a and b contain the minimum number of lags of u and y to represent \mathfrak{B} . Here we uncover another invariant property of \mathfrak{B} ; the *lag* $L(\mathfrak{B})$, which is the minimum required order of the polynomials to be able to represent \mathfrak{B} . Hence, for a minimal [\(7\)](#page-2-7), $\max(n_a, n_b) = n_r = \mathbf{L}(\mathfrak{B})$. The lag is another component of the complexity of \mathfrak{B} . The final measure of the complexity of $\mathfrak B$ is the minimal required state dimension of an LPV-SS, which we will discuss next.

³In many works on the behavioral approach, a non-singular permutation matrix Π is used to characterize the partitioning, such that $w = \Pi \begin{bmatrix} u \\ y \end{bmatrix}$. To streamline the notation, we choose $\Pi = I$ without loss of generality.

 $4A$ maximally free input means that for a given u , none of the components of y can be chosen freely for every $p \in \mathfrak{B}_{\mathbb{P}}$.

²Signals in a given data-set are denoted with the breve accent, e.g., \ddot{w} .

2) State-space representations: LPV-SS representations are standard in LPV analysis and control design. Particularly useful are LPV-SS representations with static scheduling dependence, i.e., its parameters are only dependent on $p(k)$:

$$
qx = A(p)x + B(p)u,
$$
 (8a)

$$
y = C(p)x + D(p)u,
$$
 (8b)

with $x(k) \in \mathbb{R}^{n_x}$ being the state. The *full behavior* of [\(8\)](#page-3-1) is given by

$$
\mathfrak{B}^{\text{ss}} = \{ (u, y, p, x) \in (\mathbb{R}^{n_u} \times \mathbb{R}^{n_y} \times \mathbb{P} \times \mathbb{R}^{n_x})^{\mathbb{Z}} \mid
$$
\n(8) holds}. (9)

An important feature of LPV-SA systems is that the LPV-IO representation [\(7\)](#page-2-7) has a *direct* LPV-SS realization of the form [\(8\)](#page-3-1) [21]. Particularly,

$$
\begin{bmatrix}\nA(p) & B(p) \\
C(p) & D(p)\n\end{bmatrix} =\n\begin{bmatrix}\n-a_1(p) & I_{n_y} & \cdots & 0 & b_1(p) - a_1(p)b_0(p) \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
-a_{n_a-1}(p) & 0 & \cdots & I_{n_y} & b_{n_b-1}(p) - a_{n_b-1}(p)b_0(p) \\
\hline\n-a_{n_a}(p) & 0 & \cdots & 0 & b_{n_b}(p) - a_{n_b}(p)b_0(p) \\
\hline\nI_{n_y} & 0 & \cdots & 0 & b_0(p)\n\end{bmatrix},
$$
\n(10)

where, with a slight abuse of notation, the state construction is as in [21]:

$$
x_i = qx_{i-1} + a_{i-1}(p)y - b_{i-1}(p)u, \quad x_i(k) \in \mathbb{R}^{n_y} \quad (11a)
$$

for $i \in [2, max(n_a, n_b)]$, and where

$$
x_1 = y - b_0(p)u.
$$
 (11b)

Note that with the construction [\(11\)](#page-3-2), $n_x = n_y L(\mathfrak{B})$.

Due to the direct LPV-SS realization, we have that $\pi_{u,v,p}\mathfrak{B}^{ss} = \mathfrak{B}$, i.e., the manifest behaviors defined by the IO representation [\(7\)](#page-2-7) and the LPV-SS representation [\(8\)](#page-3-1) with [\(10\)](#page-3-3) are equivalent. With this respect, we can also define minimality of [\(8\)](#page-3-1) as the minimum number of states required such that $\pi_{u,y,p}\mathfrak{B}^{ss} = \mathfrak{B}$ holds. We call this the *order* of \mathfrak{B} , which is an invariant property of \mathfrak{B} . This, in fact, is the last measure for the complexity of an LPV-SA system, which we denote by $n(\mathfrak{B})$.

For *single-input-single-output* (SISO) systems, i.e., n_u = $n_v = 1$, the direct LPV-SS realization is minimal, i.e., $n_x =$ $n(\mathfrak{B})$, if the polynomials a and b in [\(7\)](#page-2-7) are left-coprime. This means that we also have $L(\mathfrak{B}) = n(\mathfrak{B})$. For *multiple-inputmultiple-output* (MIMO) systems, i.e., n_u , $n_y > 1$, this is generally not the case and we generally also have $\mathbf{L}(\mathfrak{B}) \leq \mathbf{n}(\mathfrak{B})$. In the MIMO case, a minimal realization of [\(8\)](#page-3-1) with [\(10\)](#page-3-3) can always be obtained by means of moment matching^{[5](#page-3-4)} [23] or an LPV Kalman decomposition [24]. With both methods, the minimal realization of [\(8\)](#page-3-1) is obtained using a *constant* projection matrix that projects the state to a lower dimension. This means that the resulting (reduced) $A(p), \ldots, D(p)$ will still have static scheduling dependence and the *same* functional dependence (e.g., C is still scheduling independent).

B. Complexity and dimension of behaviors

From Section [III-A,](#page-2-8) we recovered the integers $m(\mathfrak{B})$, $L(\mathfrak{B})$, and $n(\mathfrak{B})$ that are a measure for the complexity of the behavior \mathfrak{B} of an LPV-SA system $\Sigma \in \Sigma_{n_{\text{p}},n_{\text{w}}}$. In line with [20], we characterize the complexity by the triple

$$
\mathbf{c}(\mathfrak{B}) = (\mathbf{m}(\mathfrak{B}), \mathbf{L}(\mathfrak{B}), \mathbf{n}(\mathfrak{B})),\tag{12}
$$

where $m(\mathfrak{B})$ is the number of inputs, $L(\mathfrak{B})$ is the minimal lag of the system, and $n(\mathfrak{B})$ is the order of \mathfrak{B} .

With these integer invariants defined, we will now formulate one of the key ingredients required for the solution to Prob-lem [2.](#page-2-3) More specifically, we now show that for an $L \geq L(\mathfrak{B})$, the dimension of $\mathfrak{B}_p|_{[1,L]},$ with $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]},$ is equal to $\mathbf{n}(\mathfrak{B}) + \mathbf{m}(\mathfrak{B})L.$

Lemma 1 (Dimension of $\mathfrak{B}_p|_{[1,L]}$). *Consider an LPV-SA system* $\Sigma \in \Sigma_{n_{\text{p}},n_{\text{w}}}$ *with behavior* \mathfrak{B} *and complexity* **c**(\mathfrak{B}). *Given any* $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$ *. Then,* $\dim(\mathfrak{B}_p|_{[1,L]}) = \mathbf{n}(\mathfrak{B}) + \mathbf{n}$ $m(\mathfrak{B})L$ *if and only if* $L \geq L(\mathfrak{B})$ *.*

Proof. See Appendix [I.](#page-8-0)

This result allows us to prove what we call the LPV Fundamental Lemma for the class of LPV-SA systems $\Sigma_{n_{\rm p},n_{\rm w}}$. Note that we have presented a version of Lemma [1](#page-3-5) in the meromorphic context in preliminary work [15, Cor. 1]. In this paper, we prove this result in the context of the class of LPV-SA systems.

We now have all the ingredients for the formulation of a data-driven representation of the finite-horizon behavior of LPV-SA systems, and thus solve Problems [1](#page-2-2) and [2.](#page-2-3)

IV. DATA-DRIVEN REPRESENTATIONS OF LPV-SA SYSTEMS

This section presents the first part of our main result, which is the data-driven characterization of LPV-SA systems. We will first characterize the finite-horizon behavior using the given data-set \mathcal{D}_{N_d} , providing the solution to Problem [1.](#page-2-2) This is followed by deriving a condition that concludes whether \mathcal{D}_{N_d} is 'rich' enough, i.e., whether it can fully characterize the finite-horizon behavior, providing the solution to Problem [2.](#page-2-3) We conclude this section with a note on input design.

A. Data-driven representation

We formulate a data-driven representation of $\mathfrak{B}_p|_{[1,L]}$ that is valid for any $p \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$ by means of embedding the behavior represented by the kernel representation into an LTI realization, whose behavior is constrained by a schedulingdependent kernel constraint. Isolating a single term in the kernel representation [\(1\)](#page-1-4)

$$
\left(r_{i,0} + \sum_{j=1}^{n_p} r_{i,j} p_j(k+i)\right) w(k+i),\tag{13}
$$

reveals that we can write the individual terms of [\(1\)](#page-1-4), i.e., [\(13\)](#page-3-6), in terms of the *auxiliary signal*

$$
w'(k+i) = \begin{bmatrix} 1 \\ p(k+i) \end{bmatrix} \otimes w(k+i) \in \mathbb{R}^{(1+n_{\rm p})n_{\rm w}}, \quad (14)
$$

⁵See also the implementation in LPVCORE [22].

such that

$$
(r_{i,0} + \sum_{j=1}^{n_{\rm p}} r_{i,j} p_j(k+i)) w(k+i) = \underbrace{[r_{i,0} \cdots r_{i,n_{\rm p}}]}_{r'_i} w'(k+i). \quad (15)
$$

The definition of this auxiliary signal w' allows us to embed the behavior associated with a kernel representation with shifted-affine dependency as an LTI representation with additional inputs $p(k) \otimes w(k)$, cf. [16]. The LTI embedding of [\(1\)](#page-1-4) gives

$$
R'(\mathbf{q})w' = \sum_{i=0}^{n_{\mathbf{r}}} r'_i \mathbf{q}^i w' = 0,\tag{16}
$$

with the behavior

$$
\mathfrak{B}' = \{ w' : \mathbb{T} \to \mathbb{R}^{(1+n_{\text{p}})n_{\text{w}}} \mid (16) \text{ holds} \}. \tag{17}
$$

The problem in comparing \mathfrak{B} and \mathfrak{B}' is that the entries of w ′ are *not* independent from each other in the original LPV representation [\(1\)](#page-1-4), while in the LTI embedding [\(16\)](#page-4-0) this interdependency is *ignored*. Hence, for some $w' \in \mathcal{B}'$ there might not exists a pair $(w, p) \in \mathfrak{B}$ such that $w'(k) =$ $col(w(k), p(k) \otimes w(k))$ for all k, implying that $\mathfrak{B} \subset \mathfrak{B}'$. The resulting behavior of the LTI embedding thus *overapproximates* the behavior of the LPV system, see Fig. [1c](#page-4-1) for illustration. We will counteract this over-approximation later in the data-driven representation. As the introduced auxiliary signals $p(k) \otimes w(k) \in \mathbb{R}^{n_p n_w}$ are considered to be free, we have that

$$
\mathbf{m}(\mathfrak{B}') = \mathbf{m}(\mathfrak{B}) + n_{\mathrm{p}} n_{\mathrm{w}}.\tag{18}
$$

Additionally, this consideration makes that [\(16\)](#page-4-0) is an LTI system on which we can apply the existing results on datadriven LTI representations, i.e., Willems' Fundamental Lemma and its associated results [1], [25]. These results provide that for a given data-set $\mathcal{D}_{N_d}' = \breve{w}_{[1,N_d]}'$

$$
\text{image}(\mathcal{H}_L(\breve{w}'_{[1,N_d]})) \subseteq \mathfrak{B}'|_{[1,L]},
$$
\n(19)

where equality holds if and only if the so-called *generalized persistence of excitation* condition [25] holds, i.e.,

$$
rank(\mathcal{H}_L(\breve{w}'_{[1,N_d]})) = \mathbf{n}(\mathfrak{B}) + \mathbf{m}(\mathfrak{B}')L.
$$
 (20)

Given that [\(20\)](#page-4-2) holds, we thus have that for any $w'_{[1,L]} \in$ $\mathfrak{B}'|_{[1,L]}$, there exists a $g \in \mathbb{R}^{N_d-L+1}$ such that

$$
\mathcal{H}_L(\breve{w}'_{[1,N_d]})g = \text{vec}(w'_{[1,L]})
$$
\n(21)

holds. Hence, the equality [\(21\)](#page-4-3) serves as a data-driven representation of the extended behavior \mathfrak{B}' of the LTI embedding. We will now take back into account the previously ignored interdependencies in w' .

Let us introduce the signal $w_{[1,N_{\rm d}]}^{\rm p} = (p(k) \otimes w(k))_{k=1}^{N_{\rm d}}$ such that $w'_{[1,N_d]} = \text{col}(w_{[1,N_d]}, w_{[1,N_d]}^{\text{p}})$ $\binom{P}{1,N_d}$. This allows to write [\(21\)](#page-4-3), after a permutation on the rows, as

$$
\begin{bmatrix} \mathcal{H}_L(\breve{w}_{[1,N_d]}) \\ \mathcal{H}_L(\breve{w}_{[1,N_d]}^{\breve{P}}) \end{bmatrix} g = \begin{bmatrix} \text{vec}(w_{[1,L]}) \\ \text{vec}(w_{[1,L]}^{\breve{P}}) \end{bmatrix} . \tag{22}
$$

As observed in [16], $\text{vec}(w_{1}^{\text{p}})$ $\binom{P}{[1,L]}$ = $\mathcal{P}^{n_w} \text{vec}(w_{[1,L]}),$ where $\mathcal{P}^{n_{\text{w}}} = p_{[1,L]} \circ I_{n_{\text{w}}}$. Hence,

vec
$$
(w_{[1,L]}^{\mathbf{p}}) = \mathcal{P}^{n_{\mathbf{w}}}\text{vec}(w_{[1,L]}) = \mathcal{P}^{n_{\mathbf{w}}} \mathcal{H}_L(\breve{w}_{[1,N_{\mathbf{d}}]})g.
$$
 (23)

Any g satisfying [\(23\)](#page-4-4), respects the underlying dynamic structure w.r.t. the scheduling in the signal w_{1}^{p} $\prod_{[1,L]}^{P}$, i.e., it serves as a *restriction* on the behavior of the LTI embedding. This becomes visible when [\(23\)](#page-4-4) is incorporated into [\(21\)](#page-4-3):

$$
\left[\mathcal{H}_L(\breve{w}_{[1,N_d]}^{\breve{\mathbf{p}}}) - \mathcal{P}^{n_{\mathbf{w}}} \mathcal{H}_L(\breve{w}_{[1,N_d]})\right] g = \begin{bmatrix} \text{vec}(w_{[1,L]}) \\ 0 \end{bmatrix}.
$$
\n(24)

What we see here is that the first block-row in [\(24\)](#page-4-5) characterizes the LTI part of the LPV system (associated with $r_{i,0}$), while the second block-row provides a restriction on the g vectors that provide a trajectory $w_{[1,L]}$ from the linear combination of the columns of $\mathcal{H}_L(\breve{w}_{[1,N_d]})$. This restriction is not only dependent on the information encoded in $(\breve{w}_{[1,N_d]}, \breve{p}_{[1,N_d]})$, i.e., \mathcal{D}_{N_d} , but also on the scheduling signal $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$ associated with $w_{[1,L]}$. Hence, the left-hand side of [\(24\)](#page-4-5) provides us with a *data-driven* characterization of $\mathfrak{B}_p|_{[1,L]},$ i.e., the set of all $w_{[1,L]}$'s associated with a $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}.$

Given sufficiently rich data, we now established that all possible $w_{[1,L]} \in \mathfrak{B}_p|_{[1,L]}$ are characterized by the g vectors that satisfy (24) , i.e., the g vectors that are both in the row space of $\mathcal{H}_L(\check{w}_{[1,N_\text{d}]})$ and the kernel of $\mathcal{H}_L(\check{w}_{[1,N_\text{d}]}^{\text{p}})$ $[\tilde{\mathbb{P}}_{[1,N_{\rm d}]})$ – $\mathcal{P}^{n_{\rm w}}\mathcal{H}_L(\breve{w}_{[1,N_{\rm d}]})$ for a given scheduling trajectory $p_{[1,L]}$. Hence, by defining

$$
\mathcal{N}_p = \text{kernel}\left(\mathcal{H}_L(\breve{w}_{[1,N_d]}^{\breve{p}}) - \mathcal{P}^{n_w}\mathcal{H}_L(\breve{w}_{[1,N_d]})\right),\tag{25}
$$

we have that

$$
\text{image}\left(\mathcal{H}_L(\breve{w}_{[1,N_d]})\mathcal{N}_p\right) \subseteq \mathfrak{B}_p|_{[1,L]}.\tag{26}
$$

We now established a data-driven representation of the set of $w_{[1,L]}$ sequences associated with $p_{[1,L]}$, corresponding to Problem [1](#page-2-2) (Contribution [C1\)](#page-1-1). Next, we will establish a condition on \mathcal{D}_{N_d} that guarantees [\(26\)](#page-4-6) to hold with equality, providing the solution to Problem [2](#page-2-3) (Contribution [C2\)](#page-1-2).

B. The fundamental lemma

In this section, we provide a verifiable, necessary and sufficient condition on the data \mathcal{D}_{N_d} that ensures whether [\(26\)](#page-4-6) holds with equality, providing Contribution [C2.](#page-1-2) We establish this by showing that the dimension of image $(\mathcal{H}_L(\tilde{w}_{[1,N_d]}\mathcal{N}_p))$ is strongly linked to the dimensionality of $\mathfrak{B}_p|_{[1,L]}$. This results in an so-called "identifiability condition" for LPV-SA systems, analogous to the concepts put forward in [25]. In other words, we prove the necessary and sufficient conditions that the data in \mathcal{D}_{N_d} should satisfy to be able to characterize the full $\mathfrak{B}_{\bar{p}}|_{[1,L]}$ for a given $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}.$

Theorem 1 (LPV-SA Fundamental Lemma). *Given a data-* \mathcal{S} *et* $\mathcal{D}_{N_d} \in \mathfrak{B}|_{[1,N_d]}$ from an LPV-SA system $\check{\Sigma} \in \Sigma_{n_p,n_w}$, and define \mathcal{N}_p for some $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$ as in [\(25\)](#page-4-7)*. For* $L \geq \mathbf{L}(\mathfrak{B}),$

$$
\mathfrak{B}_p|_{[1,L]} = \text{image} \left(\mathcal{H}_L(\breve{w}_{[1,N_d]}) \mathcal{N}_p \right). \tag{27}
$$

 $for\ all\ p_{[1,L]}\in \mathfrak{B}_{\mathbb{P}}|_{[1,L]},\textit{ if and only if}$

$$
rank (\mathcal{H}_L(\breve{w}_{[1,N_d]}) \mathcal{N}_p) = \mathbf{n}(\mathfrak{B}) + \mathbf{m}(\mathfrak{B})L, \qquad (28)
$$

for all $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$ *. This is equivalent to the existence of a* vector $g \in \mathbb{R}^{N_d - L + 1}$ *for any* $(w_{[1,L]}, p_{[1,L]}) \in \mathfrak{B}|_{[1,L]}$ such *that* [\(24\)](#page-4-5) *holds.*

Proof. See Appendix [II.](#page-10-0)

Theorem [1](#page-5-0) provides a necessary and sufficient dimensionality condition on the data-driven representation of $\mathfrak{B}_p|_{[1,L]}$ that is verifiable from the data-set \mathcal{D}_{N_d} . Specifically, the data can fully represent $\mathfrak{B}_{p}|_{[1,L]}$ for any $p_{[1,L]}\in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$ if and only if [\(28\)](#page-5-1) holds for all $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$. Although, the condition [\(28\)](#page-5-1) seems to result in an infinite test over all possible $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$, through the LTI embedding, we show that this reduces to a *single* test on the data in \mathcal{D}_{N_d} . We will refer to this as the *generalized persistence of excitation* (GPE) condition.

Proposition 1 (GPE condition). *Given a data-set* $\mathcal{D}_{N_d} \in$ $\mathfrak{B}|_{[1,N_{\rm d}]}$ from an LPV-SA system $\check{\Sigma} \in \Sigma_{n_{\rm p},n_{\rm w}}$. Then, [\(28\)](#page-5-1) *holds for all* $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$ *if and only if*

rank
$$
\left(\begin{bmatrix} \mathcal{H}_L(\breve{w}_{[1,N_d]}) \\ \mathcal{H}_L(\breve{w}_{[1,N_d]}^{\breve{P}}) \end{bmatrix} \right) = \mathbf{n}(\mathfrak{B}) + (\mathbf{m}(\mathfrak{B}) + n_p n_w) L.
$$
 (29)

Proof. See Appendix [III.](#page-10-1)

This result shows that the test of [\(28\)](#page-5-1), which needs to be performed for all $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$, can be reduced to a single, simple rank test on the left-hand side of [\(22\)](#page-4-8), which is only composed from the given data in \mathcal{D}_{N_d} . This condition also provides us with a lower bound for N_d :

$$
N_{\mathbf{d}} \ge (1 + n_{\mathbf{w}} n_{\mathbf{p}} + \mathbf{m}(\mathfrak{B})) L + \mathbf{n}(\mathfrak{B}) - 1, \qquad (30)
$$

i.e., the minimum number of samples in \mathcal{D}_{N_d} required to represent $\mathfrak{B}_p|_{[1,L]}$ for an arbitrary $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}.$

C. Input design

What makes Theorem [1](#page-5-0) different from the original (LPV) Fundamental Lemma in [1], [15] is that we now have a rank condition on the Hankel matrices involving trajectories of w and p , while in [1], the rank condition is only on the input signal u, i.e., $\text{rank}(\mathcal{H}_{L+\mathbf{n}(\mathfrak{B})}(\breve{u}_{[1,N_d]})) = \mathbf{m}(\mathfrak{B})(L+\mathbf{n}(\mathfrak{B})).$ The latter yields an *input design* condition, which allows you to a priori design an experiment for the construction of a datadriven representation, without taking the output of the system itself into account. It would be tempting to adopt this condition for the LPV-SA case, i.e., by taking this rank condition on the

Fig. 2: Input, scheduling, and output sequences in \mathcal{D}_{N_d} for Example [1.](#page-5-2)

Hankel matrix of $\begin{bmatrix} u \\ u^p \end{bmatrix}$. This would lead to the condition that if

$$
\operatorname{rank}\left(\begin{bmatrix} \mathcal{H}_{L+\mathbf{n}(\mathfrak{B})}(\check{u}_{[1,N_{\mathrm{d}}]})\\ \mathcal{H}_{L+\mathbf{n}(\mathfrak{B})}(\check{u}_{[1,N_{\mathrm{d}}]}) \end{bmatrix}\right) = \mathbf{m}(\mathfrak{B})(1+n_{\mathrm{p}})(\mathbf{n}(\mathfrak{B})+L),\tag{31}
$$

then [\(27\)](#page-5-3) holds. In the following counter example, we show that this is, unfortunately, not the case.

Example 1. Consider an LPV-SA system $\Sigma \in \Sigma_{n_{\text{p}},n_{\text{w}}}$ with the LPV-IO representation:

$$
y(k) + (1 + p(k - 1))y(k - 1) = u(k) + p(k - 1)u(k - 1).
$$

which has shifted-affine scheduling dependence. Note that $n(\mathfrak{B}) = m(\mathfrak{B}) = L(\mathfrak{B}) = n_p = 1$ and $n_w = 2$ for this particular system. We compute a data-driven representation of Σ for $L = 10$. For this, we generate a \mathcal{D}_{N_d} with $N_d = 40$, according to [\(30\)](#page-5-4). With $y(0) = u(0) = p(0) = 1$, we apply a scheduling signal $p_{[1,N_d]}$ with $p(k) \sim \mathcal{N}(1,0)$ and an input that is constructed as:

$$
u(k) = p(k-1)(1 - u(k-1)) + 2,
$$

to the system. Note that this input can in fact be seen as a control policy to regulate the system to $y(k) = 1$ for any scheduling sequence. The resulting input and scheduling sequences are shown in Fig. [2.](#page-5-5) By looking at these signals, one could already argue that they are persistently exciting, and, indeed, computing the rank in condition [\(31\)](#page-5-6) gives a rank of 22 (note that $\mathbf{m}(\mathfrak{B})(1 + n_{\rm p})(L + \mathbf{n}(\mathfrak{B})) = 22$). However, when inspecting the output response, we see that $y(k) = 1$ for all $k = 1, \ldots, N_d$, which is due to the construction of $u(k)$. This means that [\(28\)](#page-5-1) and thus [\(27\)](#page-5-3) will never be satisfied, showing that directly adopting the *input*-design condition from [1] does not apply for systems of the class $\Sigma_{n_{\rm p},n_{\rm w}}$. Applying the condition on the LTI embedding [\(16\)](#page-4-0) with inputs $col(u, w^p)$, gives the correct conclusion, i.e.,

rank
$$
\begin{pmatrix} \mathcal{H}_{L+n(\mathfrak{B})}(\check{u}_{[1,N_{\text{d}}]}) \\ \mathcal{H}_{L+n(\mathfrak{B})}(\check{u}_{[1,N_{\text{d}}]}^{\tilde{p}}) \\ \mathcal{H}_{L+n(\mathfrak{B})}(\check{y}_{[1,N_{\text{d}}]}^{\tilde{p}}) \end{pmatrix}
$$

= $\underbrace{(\mathbf{m}(\mathfrak{B}) + n_{\text{w}}n_{\text{p}})}_{\mathbf{m}(\mathfrak{B}')}(L+\mathbf{n}(\mathfrak{B}))$ (32)

Fig. 3: Schematic representation of the simulation problem: With a length- T_i initial trajectory (w_i, p_i) (depicted by the red data points), determine the response $(w_{\rm r}, p_{\rm r})$ (depicted by the yellow data points) using only a given data-set $\mathcal{D}_{N_{\rm d}} = (\breve{w}_{[1,N_{\rm d}]}, \breve{p}_{[1,N_{\rm d}]})$ (depicted by the blue data points).

should hold in order for [\(27\)](#page-5-3) to hold. Computing the rank as in [\(32\)](#page-5-7) with the obtained data-set gives 24, while $(m(3) +$ $n_{\rm w}n_{\rm p}(L + n(\mathfrak{B})) = 33$, concluding that the data cannot represent the considered system for $L = 10$.

From Example [1,](#page-5-2) we see that, in order to have a condition on the input (and scheduling) that a priori guarantees [\(27\)](#page-5-3) to hold, we need a condition on the design of $(\breve{u}_{[1,N_d]}, \breve{p}_{[1,N_d]})$ which guarantees that the resulting $(\text{col}(\breve{u}_{[1,N_d]}, \breve{y}_{[1,N_d]}), \breve{p}_{[1,N_d]}) \in$ $\mathfrak{B}|_{[1,N_d]}$ will satisfy [\(32\)](#page-5-7). We currently do not have a systematic solution to this problem, and see this as an important and interesting topic for future research.

V. DATA-DRIVEN SIMULATION

In this section, we consider the solution to the simulation problem in a data-driven setting, solving Problem [3.](#page-2-4) We also provide examples to illustrate the proven completeness of the data-driven representations and demonstrate the equivalence w.r.t. model-based representations. We want to emphasize that, although the data-driven simulation problem has been utilized in the LPV setting already, see [15]–[17], it has never been worked out in detail from a theoretical perspective. Therefore, we formalize the solution to the simulation problem in this section, as an extension of the LTI data-driven simulation problem that is discussed in [26].

A. The LPV data-driven simulation problem

The straight-forward formulation of the general LPV simulation problem is: Given an LPV-SA system $\Sigma \in \Sigma_{n_{\rm p},n_{\rm w}}$ with IO partitioning $w = col(u, y)$. For an initial condition and input-scheduling pair (u_r, p_r) , find the response y_r of Σ to (u_r, p_r) and the initial condition, such that $(\text{col}(u_r, y_r), p_r) \in$ $\mathfrak{B}|_{[1,T_{\mathrm{r}}]}.$

To formalize this in the data-driven setting, we will need to specify the initial condition. Classically, this is characterized by the initial state of an LPV-SS representation of B. As we will show in what follows, the initial condition can be (uniquely) expressed in terms on an *initial trajectory*. Hence, this provides a way formalize the *data-driven simulation problem* as follows:

Given a data-set $\mathcal{D}_{N_{\rm d}} \in \mathfrak{B}|_{[1,N_{\rm d}]}$ from an LPV-SA system $\check{\Sigma} \in \Sigma_{n_p,n_w}$, an input-scheduling pair $(u_{\rm r}, p_{\rm r}) \in$ $(\mathbb{R}^{n_u} \times \mathbb{P})^{[1,T_x]}$ and an initial trajectory $(w_i, p_i) \in \mathfrak{B}|_{[1,T_i]}.$ Find a response y_r of Σ to the input-scheduling pair $(u_r, p_r) \in$ $(\mathbb{R}^{n_u} \times \mathbb{P})^{[1,T_r]}$, such that $(w_i, p_i) \wedge (\text{col}(u_r, y_r), p_r) \in$ $\mathfrak{B}|_{[1,T_i+T_r]}$. The simulation problem is also illustrated in Fig. [3.](#page-6-1)

Algorithm 1: LPV data-driven simulation

Requires A data-set $\mathcal{D}_{N_d} \in \mathfrak{B}|_{[1,N_d]}$, an initial trajectory $(w_i, p_i) \in \mathfrak{B}|_{[1,T_i]}$, and an input-scheduling trajectory $(u_{\rm r}, p_{\rm r}) \in \pi_{\rm u,p} \left. \mathfrak{B} \right|_{[1,T_{\rm r}]}.$

1: Compute a
$$
g
$$
 that satisfies

$$
\begin{bmatrix}\n\mathcal{H}_{T_i}(\check{w}_{[1,N_d-T_r]}) \\
\mathcal{H}_{T_r}(\check{w}_{[T_i+1,N_d]}) \\
\mathcal{H}_{\bar{T}}(\check{w}_{[1,N_d]}^{\check{P}}) - \mathcal{P}_{i,r}^{n_w} \mathcal{H}_{\bar{T}}(\check{w}_{[1,N_d]})\n\end{bmatrix} g = \begin{bmatrix}\n\text{vec}(w_i) \\
\text{vec}(u_r) \\
0\n\end{bmatrix},
$$
\n(34)

with $\overline{T} = T_i + T_r$ and $\mathcal{P}_{i,r}^{n_w} = (p_i \wedge p_r) \circ I_{n_w}$. 2: Compute y_r via

$$
\text{vec}(y_r) = \mathcal{H}_{T_r}(\breve{y}_{[T_i+1,N_d]})g. \tag{35}
$$

Outputs y_r

B. Trajectory-based initial condition

We now show that the initial condition x of the response (w_r, p_r) can be uniquely determined with a length- T_i initial trajectory if T_i is larger than $\mathbf{L}(\mathfrak{B})$.

Lemma 2. *Consider an LPV-SA system* $\Sigma \in \Sigma_{n_p,n_w}$ *with behavior* \mathfrak{B} *. Given* $(w_i, p_i) \in (\mathbb{R}^{n_w} \times \mathbb{P})^{[1,T_i]}$ *. If* $T_i \geq L(\mathfrak{B})$ *and*

$$
(w_{\mathbf{i}}, p_{\mathbf{i}}) \wedge (w_{\mathbf{r}}, p_{\mathbf{r}}) \in \mathfrak{B}|_{[1, T_{\mathbf{i}} + T_{\mathbf{r}}]}, \tag{33}
$$

then the initial state $x \in \mathbb{R}^{n(\mathfrak{B})}$ *of* (w_{r}, p_{r}) *can be uniquely* expressed in terms of (w_i, p_i) .

Proof. See Appendix [IV.](#page-10-2) ■

The formal problem formulation in Section [V-A](#page-6-2) does *not* require the simulation of a unique response for y_r , which is, however, often desired. The result of Lemma [2](#page-6-3) provides us with a condition ($T_i \geq L(\mathfrak{B})$) that ensures a unique response to an input-scheduling pair. Note that this is next to the requirement that the data should be able to represent the finitehorizon behavior of Σ . In the next section, we give a solution to the LPV data-driven simulation problem.

C. The LPV data-driven simulation algorithm

To satisfy $(w_i, p_i) \wedge (\text{col}(u_r, y_r), p_r) \in \mathfrak{B}|_{[1, T_i + T_r]},$ we know from Theorem [1](#page-5-8) and Proposition 1 that (28) and thus (29) should hold for $L = T_i + T_r$. This allows to write

$$
\left[\begin{array}{cc} \mathcal{H}_{\bar{T}}(\check{w}_{[1,N_\text{d}]}^{\bar{p}}) \\ \hline \mathcal{H}_{\bar{T}}(\check{w}_{[1,N_\text{d}]}^{\bar{p}}) - \mathcal{P}_{i,r}^{n_\text{w}} \mathcal{H}_{\bar{T}}(\check{w}_{[1,N_\text{d}]}^{\bar{p}}) \end{array}\right] g = \left[\begin{array}{c} \text{vec}(w_i) \\ \text{vec}(u_r) \\ \text{vec}(u_r) \\ -\bar{0} \end{array}\right],
$$

where $\overline{T} = T_i + T_r$ and $\mathcal{P}_{i,r}^{n_w} = (p_i \wedge p_r) \odot I_{n_w}$. For a given w_i , u_r , and scheduling sequence $p_i \wedge p_r$, this is a linear set of equations in the unknowns g and y_r . Partitioning of the Hankel matrices on the left-hand side provides the algorithm for LPV data-driven simulation, which is given in Algorithm [1.](#page-6-4) The LPV extensions of the special cases discussed in [26], e.g., zero input response, zero initial condition response, impulse response, etc. directly follow from the underlying technique

Fig. 4: Schematic representation of a mass-spring-damper system with a spring that is varying along measurable signal p . The input of the system is a force u , while the output is the measured position y .

TABLE I: Parameters of the MSD system.

25 [kg]	1 [N/m]	10 [N/m] 1 [Ns/m] 0.1 [s]	

in the LPV data-driven simulation algorithm. This also is the case for, e.g., recursive implementation of Algorithm [1](#page-6-4) to simulate for $T_r \rightarrow \infty$, data-driven simulation for LPV embeddings of nonlinear systems via iterative scheduling refinement (see [27]), or data-based scheduling estimation. These topics are interesting but not the focus of the paper and will therefore not be discussed.

D. Simulation examples

To illustrate the validity and effectiveness of the data-driven representations, we use a *mass-spring-damper* (MSD) system where the spring has a stiffness parameter that is varying along a measurable signal p . Such a model is often used as a simplified representation of a physical system. An example can be, e.g., the linear axis of a water-jet cutter, where the stiffness of the cable-slab is dependent on the water-flow of the jet. A schematic representation of the MSD system is given in Fig. [4.](#page-7-1) The input u is the force [N] exerted on the mass m , and the output y is the measured position [m] of the mass. The damper has damping coefficient d , while the spring has a stiffness coefficient described by the function $k(p)$. The variation of $k(p)$ is described by

$$
k(p(k)) = k_0 + k_1 p(k), \quad p(k) \in [-1, 1].
$$

Euler discretization of the CT MSD dynamics with sampling time T_s gives the following LPV-IO representation:

$$
y(k) + \left(\frac{dT_s}{m} - 2\right) y(k-1)
$$

+
$$
\left(1 + \frac{k_0 T_s^2 - dT_s}{m} + \frac{k_1 T_s^2}{m} p(k-2)\right) y(k-2)
$$

=
$$
\frac{T_s^2}{m} u(k-2). \quad (36)
$$

The parameters of the system are given in Table [I.](#page-7-2) Note that the system is SISO, and that $L(\mathfrak{B}) = n(\mathfrak{B}) = 2$. In this example, we want to perform a data-driven simulation of this system for $T_r = 35$ samples (corresponding to 3.5) seconds), without having access to [\(36\)](#page-7-3) or its parameters; only a measured data-set from the system is available. We consider three cases:

Case [1](#page-5-0): The conditions of Theorem 1 hold and $T_i \geq L(\mathfrak{B})$; Case 2: The conditions of Theorem [1](#page-5-0) do not hold and $T_i \geq$ $\mathbf{L}(\mathfrak{B});$

Fig. 5: Data-dictionary measured from the LPV MSD system with $N_{\rm d} = 161.$

Case 3: The conditions of Theorem [1](#page-5-0) hold and $T_i < L(\mathfrak{B})$. For the Cases [1](#page-7-4) and [2,](#page-7-5) we choose $T_i = 5$, while for Case [3](#page-7-6) $T_i = 1$. We generate a data-dictionary \mathcal{D}_{N_d} of length $N_d =$ $(1 + n_w n_p + m(\mathfrak{B}))L + n(\mathfrak{B}) - 1 = 161$, and take, for Case [2,](#page-7-5) $N_d = 151$ by disregarding the last 10 samples in \mathcal{D}_{N_d} . The data-dictionary used in this example is shown in Fig. [5.](#page-7-7) With [\(29\)](#page-5-9), it is verified that \mathcal{D}_{N_d} satisfies the GPE condition and can represent the behavior on the horizon T_i+T_r for Cases [1](#page-7-4) and [3,](#page-7-6) while the condition does not hold true for Case [2.](#page-7-5)

We now use Algorithm [1](#page-6-4) for the aforementioned three cases. By solving [\(34\)](#page-6-5) in the least-squares sense and observe that, as expected, the following norm

$$
\left\| \begin{bmatrix} \mathcal{H}_{T_1}(\check{w}_{[1,N_\text{d}-T_\text{r}]}) \\ \mathcal{H}_{T_1}(\check{w}_{[T_1+1,N_\text{d}]}^{\text{p}}) \\ \mathcal{H}_{\bar{T}}(\check{w}_{[1,N_\text{d}]}^{\text{p}}) - \mathcal{P}_{1,\text{r}}^{n_\text{w}} \mathcal{H}_{\bar{T}}(\check{w}_{[1,N_\text{d}]}^{\text{p}}) \end{bmatrix} g - \begin{bmatrix} \text{vec}(w_i) \\ \text{vec}(u_r) \\ 0 \end{bmatrix} \right\|_2
$$

is zero for Cases [1](#page-7-4) and [3,](#page-7-6) while for Case [2](#page-7-5) the norm is computed as 0.45. Computing the simulated outputs for the different cases with [\(35\)](#page-6-6) gives the results in Fig. [6,](#page-8-1) which are compared to a model-based simulation of [\(36\)](#page-7-3) shown in red. In Case [1,](#page-7-4) all the conditions for LPV data-driven simulation are satisfied, and indeed the model-based and databased simulations coincide. The simulation result for Case [2](#page-7-5) shows that y_r is both not connected to the initial trajectory and not coinciding with the model-based simulation, i.e., the behavior, which contains the true trajectory, is not represented by the data in the smaller \mathcal{D}_{N_d} . The solution to [\(34\)](#page-6-5) with Case [3](#page-7-6) results in a subspace of g 's and thus a set of possible y_r 's. This is because with $T_i < L(\mathfrak{B})$, the problem [\(34\)](#page-6-5) is under-determined, i.e., there are infinitely many solutions for y_r for which $(\text{col}(u_i, y_i), p_i) \wedge (\text{col}(u_r, y_r), p_r) \in \mathfrak{B}|_{[1, T_i + T_r]}.$ We have illustrated this by plotting a number of valid solutions for y_r , all of which are a valid continuation of the initial trajectory.

VI. CONCLUSIONS

In this paper, we derived a data-driven representation for LPV-SA systems, i.e., systems that can be represented by an LPV-IO representation with shifted-affine scheduling dependence. We provide a (necessary and sufficient) rank test on a matrix constructed from the data to analyze whether the

Fig. 6: Simulation results for Cases [1–](#page-7-4)[3.](#page-7-6) The red solid line is the model-based simulation, the initial trajectory is indicated with the light-blue dotted line and the gray shaded area, while the blue dotted line represents the data-driven simulation result. For Case [1](#page-7-4) the model-based and data-based simulations coincide. Case [2](#page-7-5) results in a simulated output that is not connected to the initial trajectory and hence does not coincide with the model-based simulation. The datadriven simulation results for Case [3](#page-7-6) show a continuation of the initial trajectory, but the simulated output trajectory is not unique which is illustrated by plotting several valid solutions for y_r .

data is able to fully represent the finite-horizon behavior of the LPV system. Additionally, we provided a formal solution to the LPV data-driven simulation problem, supported with a thorough analysis by means of an example. These results fill the current gaps in the theory on data-driven LPV analysis and control methods that are already present in the literature, and furthermore serve as a good baseline for the development of data-driven methods for nonlinear systems.

As a future work, we aim to generalize the results to other useful dependency classes and to handling noisy data-sets. Moreover, we consider the formulation of conditions on the input and scheduling that allow for experiment design with a priori guarantees on the satisfaction of [\(29\)](#page-5-9) an important topic for future research.

APPENDIX I PROOF OF LEMMA [1](#page-3-5)

Before we can give the proof for Lemma [1,](#page-3-5) we first need some intermediate results. We first write the LPV-SS representation [\(8\)](#page-3-1) with [\(10\)](#page-3-3) in a structured form. This, in turn, allows us to draw conclusions on observability of [\(8\)](#page-3-1) with [\(10\)](#page-3-3). Finally, these are used to give the proof of Lemma [1.](#page-3-5)

A. Structured LPV-SS form

Through the state construction [\(11\)](#page-3-2) and the affine parametrization of the scheduling dependent polynomial coefficients of the kernel/IO representations, we can write the LPV-SS representation in terms of $x(k)$, $u(k)$, $p(k) \otimes y(k)$, $p(k) \otimes u(k)$, and $p(k) \otimes p(k) \otimes u(k)$ by splitting up [\(10\)](#page-3-3) in the scheduling independent and scheduling dependent parts:

$$
x(k+1) = A_0x(k) + B_0u(k) + A_p p(k) \otimes x_1(k)
$$

+
$$
B_p p(k) \otimes u(k) + B_{pp} p(k) \otimes p(k) \otimes u(k),
$$

(37a)

$$
y(k) = Cx(k) + D_0u(k) + D_p p(k) \otimes u(k),
$$
 (37b)

with A_0, \ldots, D_p as in [\(38\)](#page-10-3) on the next page. Note that $x_1(k)$ is as in [\(11b\)](#page-3-7), i.e., $x_1(k) \in \mathbb{R}^{n_y}$. The formulation [\(37\)](#page-9-0) separates the LTI behavior from the parameter-varying behavior. By substituting [\(11b\)](#page-3-7) partially in [\(37a\)](#page-9-1) (only in $p(k) \otimes x_1(k)$) gives a state equation written in terms of a scheduling independent state and the manifest variables:

$$
x(k+1) = A_0x(k) + B_0u(k) + A_p p(k) \otimes y(k)
$$

+ $\tilde{B}_p p(k) \otimes u(k) + \tilde{B}_{pp} p(k) \otimes p(k) \otimes u(k)$, (39)

where $\tilde{B}_{\rm p} = B_{\rm p} - A_{\rm p}(I_{n_{\rm p}} \otimes D_0)$ and $\tilde{B}_{\rm pp} = B_{\rm pp} - A_{\rm p}(I_{n_{\rm p}} \otimes D_0)$ D_p). With this form, we can express a length L trajectory in $\mathfrak{B}|_{[1,L]}$ as follows

vec
$$
\text{vec}(y_{[1,L]}) = \mathcal{O}_L \mathbf{x} + \mathcal{F}_L \text{vec}(u_{[1,L]}) + \mathcal{O}_L^{\text{P}} \text{vec}(y_{[1,L]}^{\text{P}}) + \mathcal{F}_L^{\text{P}} \text{vec}(u_{[1,L]}^{\text{P}}) + \mathcal{F}_L^{\text{PP}} \text{vec}(u_{[1,L]}^{\text{PP}}),
$$
 (40a)

with $u_{[1,L]}^{\text{pp}} = (p(k) \otimes p(k) \otimes u(k))_{k=1}^{L}$ and initial condition $x \in \mathbb{R}^{n_x^1, n_y^1}$ where

$$
\mathscr{O}_L = \begin{bmatrix} C \\ CA_0 \\ \vdots \\ CA_0^{L-1} \end{bmatrix}, \qquad \mathscr{T}_L = \begin{bmatrix} D_0 & 0 & \cdots & 0 \\ CB_0 & D_0 & \cdots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ CA_0^{L-1}B_0 & \cdots & CB_0 & D_0 \end{bmatrix},
$$

$$
\mathscr{O}_L^{\mathbf{p}} = \begin{bmatrix} 0 & 0 & \cdots & 0 \\ CA_1 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ CA_0^{L-1}A_p & \cdots & CA_p & 0 \end{bmatrix},
$$

$$
\mathscr{T}_L^{\mathbf{p}} = \begin{bmatrix} D_p & 0 & \cdots & 0 \\ C\hat{B}_p & D_p & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ CA_0^{L-1}\hat{B}_p & \cdots & C\hat{B}_p & D_p \end{bmatrix},
$$

$$
\mathscr{T}_L^{\mathbf{p}} = \begin{bmatrix} 0 & 0 & \cdots & 0 \\ C\hat{B}_{pp} & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ CA_0^{L-1}\hat{B}_{pp} & \cdots & C\hat{B}_{pp} & 0 \end{bmatrix}.
$$
(40b)

With these formulations, we now provide observability and minimality properties of the LPV-SS representation, which are required for the proof of Lemma [1.](#page-3-5)

B. Observability properties of the structured LPV-SS

We first introduce the notion of *complete state-observability* from [11]:

Definition 1 (Complete state-observability [11]). An LPV-SS representation [\(8\)](#page-3-1) is called *completely state-observable*, if for all $(u, x, y, p) \in \mathfrak{B}^{ss}$, $(u, x', y, p) \in \mathfrak{B}^{ss}$ it holds that $x = x'$.

From which the next result follows:

Lemma 3. *Given a shifted-affine LPV-IO realization* [\(7\)](#page-2-7) *for which the polynomials in* [\(6\)](#page-2-9) *are left-coprime. Any LPV-SS representation* [\(10\)](#page-3-3) *that is constructed from this LPV-IO representation is completely state-observable.*

Proof. Consider [\(40\)](#page-9-2) for some $L \geq n_{x}$. Computing \mathscr{O}_{L} for this L gives

$$
\mathscr{O}_L = \begin{bmatrix} I & 0 & \cdots & \cdots & \cdots & 0 \\ -a_{1,0} & I & 0 & \cdots & \cdots & 0 \\ a_{1,0}^2 - a_{2,0} & -a_{1,0} & I & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \end{bmatrix},
$$

i.e., \mathcal{O}_L is a tall, lower-triangular matrix with 1's on the diagonal, i.e., \mathscr{O}_L is full column-rank. Hence, for a given $(u_{[1,L]}, y_{[1,L]}, p_{[1,L]}) \in \pi_{u,y,p} \mathfrak{B}^{ss}$, x can be uniquely determined through [\(40\)](#page-9-2), after which the state trajectory is governed by [\(39\)](#page-9-3). This implies that the state trajectory for $k \geq 1$ is unique. Taking $L \rightarrow \infty$ gives, together with the time-invariance property of LPV systems, that for $(u, y, p) \in$ $\pi_{u,v,p} \mathfrak{B}^{ss}$ the corresponding state trajectory x is unique, i.e., the representation is completely state-observable.

This result states that for any scheduling sequence in $\mathfrak{B}_{\mathbb{P}}$, the representation [\(10\)](#page-3-3) is observable. We have already established in Section [III-A.2](#page-3-8) that we can always obtain a minimal LPV-SS with static scheduling dependence. Note that this minimal realization will admit the same structure as discussed in Section [I-A,](#page-8-2) i.e., we can always formulate [\(40\)](#page-9-2) with an x of dimension $\mathbf{n}(\mathfrak{B})$, where the matrices $\mathscr{O}_{T_r}, \ldots, \mathscr{T}_{T_r}^{\text{pp}}$ are constructed as in [\(40b\)](#page-9-4).

Finally, we have the following result, which is key in deriving the proof for Lemma [1.](#page-3-5) This result links the rank of the 'LTI part' of the observability matrix, i.e., \mathscr{O}_L to the invariant integer $L(\mathfrak{B})$.

Proposition 2. *Given a minimal* [\(10\)](#page-3-3) *constructed from* [\(7\)](#page-2-7) *where* [\(6\)](#page-2-9) *are left-coprime. Then,* $rank(\mathcal{O}_L) = n(\mathfrak{B})$ *if and only if* $L \geq L(\mathfrak{B})$ *.*

Proof. First note that by Lemma [3,](#page-9-5) the representation is observable for *any* $p \in \mathfrak{B}_{\mathbb{P}}$, including $0 \in \mathfrak{B}_{\mathbb{P}}$. Then it follows from [28, Thm. 6] and [11, Sec. 4.3] that the observability index and n_r , i.e., $\mathbf{L}(\mathfrak{B})$ are equal. This implies that rank $(\mathscr{O}_L) = \mathbf{n}(\mathfrak{B})$ if and only if $L \geq n_r = \mathbf{L}(\mathfrak{B})$, concluding the proof.

We are now ready to give the proof of Lemma [1.](#page-3-5)

C. Proof of Lemma [1](#page-3-5)

Proof. Take an arbitrary $p_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$ and an associated $\text{col}(u_{[1,L]}, y_{[1,L]}) \in \mathfrak{B}_p|_{[1,L]}$. Now consider the formulation of this trajectory in terms of [\(40\)](#page-9-2). We can write

$$
\text{vec}(u_{[1,L]}^{\mathbf{p}})=(p_{[1,L]}\circledcirc I_{n_{\mathbf{u}}})\text{vec}(u_{[1,L]}),
$$

similarly for $\text{vec}(y)$ ^p $[1,L]$). Furthermore, note that $vec(u_{[1,L]}^{PP})$ $_{[1,L]}^{\mathsf{pp}})$ can be written as

$$
\text{vec}(u_{[1,L]}^{\text{pp}}) = (p_{[1,L]} \circlearrowright I_{n_{\text{u}}n_{\text{p}}})\text{vec}(u_{[1,L]}^{\text{p}}).
$$

$$
A_{0} = \begin{bmatrix} -a_{1,0} & I & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ -a_{n_{a}-1,0} & 0 & \dots & I \\ -a_{n_{a},0} & 0 & \dots & 0 \end{bmatrix}, \qquad B_{0} = \begin{bmatrix} b_{1,0}-a_{1,0}b_{0,0} \\ \vdots & \vdots \\ b_{n_{b}-1,0}-a_{n_{b}-1,0}b_{0,0} \\ b_{n_{b},0}-a_{n_{b},0}b_{0,0} \end{bmatrix}, \qquad B_{pp} = \begin{bmatrix} -a_{1,1}b_{0,1} & \dots & -a_{1,n_{p}}b_{0,n_{p}} \\ \vdots & \ddots & \vdots \\ -a_{n_{a},n}b_{0,1} & \dots & -a_{n_{a},n_{p}}b_{0,n_{p}} \end{bmatrix}, \qquad D_{0} = b_{0,0}, \qquad (38a)
$$

$$
A_{p} = \begin{bmatrix} -a_{1,1} & \dots & -a_{1,n_{p}} \\ \vdots & \ddots & \vdots \\ -a_{n_{a},1} & \dots & -a_{n_{a},n_{p}} \end{bmatrix}, \qquad B_{p} = \begin{bmatrix} b_{1,1} & \dots & b_{1,n_{p}} \\ \vdots & \ddots & \vdots \\ b_{n_{b},1} & \dots & b_{n_{b},n_{p}} \end{bmatrix}, \qquad C = \begin{bmatrix} I & 0 & \cdots & 0 \end{bmatrix}, \qquad D_{p} = \begin{bmatrix} b_{0,1} & \dots & b_{0,n_{p}} \end{bmatrix}
$$

(38b)

Hence, with $\mathcal{P}^{n_u} = p_{[1,L]} \circlearrowright I_{n_u}$, $\mathcal{P}^{n_y} = p_{[1,L]} \circlearrowright I_{n_y}$, and $\mathcal{P}^{n_{\rm u}n_{\rm p}} = p_{[1,L]} \odot I_{n_{\rm u}n_{\rm p}}$, we can rewrite [\(40\)](#page-9-2) with $x \in \mathbb{R}^{n(\mathfrak{B})}$ as

$$
(I - \mathcal{O}_L^p \mathcal{P}^{n_y}) \text{ vec}(y_{[1,L]}) = \mathcal{O}_L \mathbf{x}
$$

+ $(\mathcal{I}_L + \mathcal{I}_L^p \mathcal{P}^{n_u} + \mathcal{I}_L^{p_p} \mathcal{P}^{n_u n_p} \mathcal{P}^{n_u}) \text{ vec}(u_{[1,L]}).$ (41)

Hence, to characterize the manifest behavior of the LPV system for a given scheduling sequence $p_{[1,L]}$, we can use [\(41\)](#page-10-4) to express the dynamic relation of any trajectory in $\mathfrak{B}_p|_{[1,L]}$ with

$$
\begin{bmatrix} I & 0 \\ 0 & I - \mathcal{O}_L^{\mathbf{p}} \mathcal{P}^{n_{\mathbf{y}}} \end{bmatrix} \text{vec}(w_{[1,L]}) =
$$
\n
$$
\begin{bmatrix} 0 & I \\ \mathcal{O}_L & \mathcal{T}_L + \mathcal{T}_L^{\mathbf{p}} \mathcal{P}^{n_{\mathbf{u}}} + \mathcal{T}_L^{\mathbf{p}} \mathcal{P}^{n_{\mathbf{u}} n_{\mathbf{p}}} \mathcal{P}^{n_{\mathbf{u}}} \end{bmatrix} \begin{bmatrix} \mathbf{x} \\ \text{vec}(u_{[1,L]}) \end{bmatrix}.
$$
\n(42)

As $\mathcal{O}_L^{\mathbf{p}}$ is a strictly lower block-triangular matrix and \mathcal{P}^{n_y} is a block diagonal matrix, $\mathcal{O}_L^{\mathbf{p}} \mathcal{P}^{n_{\mathbf{y}}}$ is always strictly lower triangular. Therefore,

$$
\begin{bmatrix} I & 0 \\ 0 & I - \mathcal{O}_L^{\mathbb{P}} \mathcal{P}^{n_{\mathbf{y}}} \end{bmatrix}
$$
 (43)

is nonsingular. Thus, we can write

$$
\text{vec}(w_{[1,L]}) = \underbrace{\begin{bmatrix} I & 0 \\ 0 & I - \mathcal{O}_L^{\mathbf{p}} \mathcal{P}^{n_y} \end{bmatrix}^{-1} \begin{bmatrix} 0 & I \\ \mathcal{O}_L & \mathcal{Q} \end{bmatrix}}_{\mathcal{B}_p} \left[\text{vec}(u_{[1,L]}) \right],
$$
\n(44)

with $\mathscr{Q} = \mathscr{T}_L + \mathscr{T}_L^{\mathbf{p}} \mathcal{P}^{n_u} + \mathscr{T}_L^{\mathbf{p}} \mathcal{P}^{n_u n_p} \mathcal{P}^{n_u}$. Since w, p were chosen arbitrarily, we conclude that the columns of \mathcal{B}_p form a basis for $\mathfrak{B}_p|_{[1,L]}$. The dimension of this basis is purely governed by $\begin{bmatrix} 0 & I \\ \mathcal{O}_L & \mathcal{Q} \end{bmatrix}$, because [\(43\)](#page-10-5) is nonsingular. To conclude the proof, we observe that because the LPV-SS representation is minimal and $L \geq L(\mathfrak{B})$, Proposition [2](#page-9-6) gives that

$$
rank\left(\begin{bmatrix} 0 & I \\ \mathscr{O}_L & \mathscr{Q} \end{bmatrix}\right) = \mathbf{n}(\mathfrak{B}) + \mathbf{m}(\mathfrak{B})L,
$$

i.e., rank $(\mathcal{B}_p) = \mathbf{n}(\mathfrak{B}) + \mathbf{m}(\mathfrak{B})L = \dim(\text{image}(\mathcal{B}_p))$ $\dim(\left.\mathfrak{B}_{p}\right|_{[1,L]}$ $\sum_{i=1}^{n}$

APPENDIX II PROOF OF THEOREM [1](#page-5-0)

Proof. First, note that $\mathfrak{B}_p|_{[1,L]}$ is a linear subspace. From Lemma [1,](#page-3-5) we know that for $L \geq L(\mathfrak{B})$, $\dim(\mathfrak{B}_p|_{[1,L]}) =$ $\mathbf{m}(\mathfrak{B}) + \mathbf{m}(\mathfrak{B})L$. Hence, if [\(27\)](#page-5-3) holds, then $\dim(\mathfrak{B}_p|_{[1,L]}) =$ $\dim(\text{image}(\mathcal{H}_L(\tilde{w}_{[1,N_d]})\mathcal{N}_p)) = \mathbf{n}(\mathfrak{B}) + \mathbf{m}(\mathfrak{B})L$, i.e., [\(28\)](#page-5-1) holds, which concludes the ' $(27) \Rightarrow (28)$ $(27) \Rightarrow (28)$ $(27) \Rightarrow (28)$ ' direction.

Now we show the ' $(27) \leftarrow (28)$ $(27) \leftarrow (28)$ $(27) \leftarrow (28)$ ' direction. Consider [\(24\)](#page-4-5) and an arbitrary scheduling sequence $\hat{p}_{[1,L]} \in \mathfrak{B}_{\mathbb{P}}|_{[1,L]}$. For any g that is both in the row space of $\mathcal{H}_L(\breve{w}_{[1,N_d]})$ and in the kernel of $\mathcal{H}_L(\breve{\vec{w}}_{\textrm{tr}}^{\breve{\mathbf{p}}}$ $(\tilde{P}_{[1,N_d]}) - \hat{\mathcal{P}}^{n_u} \mathcal{H}_L(\breve{w}_{[1,N_d]})$ we obtain a trajectory $\hat{w}_{[1,L]}$. Based on the derivations in Section [IV-](#page-3-9)[A,](#page-3-9) we conclude that $(\hat{w}_{[1,L]}, \hat{p}_{[1,L]})$ trivially satisfies [\(1\)](#page-1-4), i.e., $(\hat{w}_{[1,L]}, \hat{p}_{[1,L]}) \in \mathfrak{B}|_{[1,L]}$ and thus $\hat{w}_{[1,L]} \in \mathfrak{B}_{\hat{p}}|_{[1,L]}.$ Hence, for this fixed scheduling sequence $\hat{p}_{[1,L]}$, the space spanned by image $(\mathcal{H}_L(\breve{w}_{[1,N_d]})\mathcal{N}_{\hat{p}})$ is a subspace of $\mathfrak{B}_p|_{[1,L]},$ i.e.,

$$
\text{image}(\mathcal{H}_L(\breve{w}_{[1,N_d]})\mathcal{N}_{\hat{p}}) \subseteq \mathfrak{B}_p|_{[1,L]}.
$$
 (45)

Therefore, as the dimension of $\mathfrak{B}_p|_{[1,L]}$ is equal to $\mathbf{n}(\mathfrak{B})$ + $m(\mathfrak{B})L$, we have that if [\(28\)](#page-5-1) holds, [\(45\)](#page-10-6) must hold with equality, i.e., [\(27\)](#page-5-3) must hold. The proof of the last statement in the theorem follows directly from the above reasoning and the derivations in Section [IV-A.](#page-3-9)

APPENDIX III PROOF OF PROPOSITION [1](#page-5-8)

Proof. Note that through [\(18\)](#page-4-9), the right-hand side of condition [\(29\)](#page-5-9) is equivalent to the right-hand side of [\(20\)](#page-4-2). Then the proof follows from the fact that $(20) \Leftrightarrow (19)$ $(20) \Leftrightarrow (19)$ $(20) \Leftrightarrow (19)$, from which (24) is obtained without any loss of equivalence. From Theorem [1](#page-5-0) we have that $(24) \Leftrightarrow (28)$ $(24) \Leftrightarrow (28)$ $(24) \Leftrightarrow (28)$, which concludes the proof.

APPENDIX IV PROOF OF LEMMA [2](#page-6-3)

Proof. Consider the direct LPV-SS realization of Σ with state dimension $n(\mathfrak{B})$ and behavior \mathfrak{B}^{ss} . Consider a trajectory $(u_{[k_1,k_2]}, y_{[k_1,k_2]}, p_{[k_1,k_2]}, \underline{x}_{[k_1,k_2]}) \in \mathfrak{B}^{\text{ss}}|_{[k_1,k_2]},$ with $k_1 \geq k_2$, and let us denote $\overline{k} = k_2 - k_1$ and $y_{\overline{k}} =$ $vec(y_{[k_1,k_2]})$ for brevity (similarly for u and p). From the discussion in Section [I-A,](#page-8-2) we know that we can express $(u_{[k_1,k_2]}, y_{[k_1,k_2]}, p_{[k_1,k_2]}) \in \pi_{\text{u}, \text{y}, \text{p}} \, \mathfrak{B}^{\text{ss}}|_{[k_1,k_2]}$ in the form of [\(40\)](#page-9-2):

where

 $(I - \mathscr{O}_{\bar{k}}^{\mathbf{p}} \mathcal{P}_{[k_1}^{n_{\mathrm{y}}}$

$$
\mathscr{Q}_{\bar{k}}=\mathscr{T}_{\bar{k}}+\mathscr{T}^{\mathrm{P}}_{\bar{k}}\mathcal{P}_{[k_1,k_2]}^{n_\mathrm{u}}+\mathscr{T}^{\mathrm{PP}}_{\bar{k}}\mathcal{P}_{[k_1,k_2]}^{n_\mathrm{u}n_\mathrm{p}}\mathcal{P}_{[k_1,k_2]}^{n_\mathrm{u}},
$$

 $(\binom{n_y}{[k_1,k_2]}\y_{\bar{k}} = \mathscr{O}_{\bar{k}}x(k_1) + \mathscr{Q}_{\bar{k}}u_{\bar{k}}$ (46)

with $\mathcal{P}_{[k_1,k_2]}^{n_u} = p_{[k_1,k_2]} \circlearrowright I_{n_u}, \ \mathcal{P}_{[k_1,k_2]}^{n_y} = p_{[k_1,k_2]} \circlearrowright I_{n_y}$, and $\mathcal{P}_{[k_1,k_2]}^{n_{\text{u}}n_{\text{p}}} = p_{[k_1,k_2]} \odot I_{n_{\text{u}}n_{\text{p}}}$. Furthermore, we can also express $x(k_2)$ by recursive application of [\(39\)](#page-9-3) from $x(k_1)$:

$$
x(k_2) = A_0^{k_2 - k_1} x(k_1) + \mathscr{A}_{\bar{k}} \mathcal{P}_{[k_1, k_2]}^{n_y} y_{\bar{k}} + \mathscr{B}_{\bar{k}} u_{\bar{k}} +
$$

$$
\mathscr{B}_{\bar{k}}^{\mathbf{p}} \mathcal{P}_{[k_1, k_2]}^{n_u} u_{\bar{k}} + \mathscr{B}_{\bar{k}}^{\mathbf{p}} \mathcal{P}_{[k_1, k_2]}^{n_u} \mathcal{P}_{[k_1, k_2]}^{n_u} u_{\bar{k}}, \quad (47)
$$

where

$$
\mathscr{A}_{\bar{k}} = [A_0^{\bar{k}-1} A_{\bar{p}} \cdots A_{\bar{p}} 0], \quad \mathscr{B}_{\bar{k}} = [A_0^{\bar{k}-1} B_0 \cdots B_0 0], \mathscr{B}_{\bar{k}}^{\bar{p}} = [A_0^{\bar{k}-1} \tilde{B}_{\bar{p}} \cdots \tilde{B}_{\bar{p}} 0], \quad \mathscr{B}_{\bar{k}}^{\bar{p}p} = [A_0^{\bar{k}-1} \tilde{B}_{\bar{p}p} \cdots \tilde{B}_{\bar{p}} 0].
$$

We will now express $x(k_2)$ in terms of only the trajectories $(\text{col}(u_{[k_1,k_2]}, y_{[k_1,k_2]}), p_{[k_1,k_2]})$. Suppose $\mathscr O_{\bar k}$ has a left-inverse, then we obtain the following expression for $x(k_1)$:

$$
x(k_1) = \mathcal{O}_{\bar{k}}^+(I - \mathcal{O}_{\bar{k}}^{\mathbf{p}} \mathcal{P}_{[k_1,k_2]}^{n_{\mathbf{y}}}) y_{\bar{k}} - \mathcal{O}_{\bar{k}}^+ \mathcal{Q}_{\bar{k}} u_{\bar{k}}, \qquad (48)
$$

where $\mathcal{O}_{\overline{k}}^+$ denotes the left-inverse. Substitution of [\(48\)](#page-11-0) in [\(47\)](#page-10-7) gives

$$
x(k_2) = \left(A_0^{k_2 - k_1} \mathcal{O}_{\bar{k}}^+ (I - \mathcal{O}_{\bar{k}}^{\mathbf{p}} \mathcal{P}_{[k_1, k_2]}^{n_y}) + \mathscr{A}_{\bar{k}} \mathcal{P}_{[k_1, k_2]}^{n_y}\right) y_{\bar{k}} + \left(A_0^{k_2 - k_1} \mathcal{O}_{\bar{k}}^+ \mathscr{Q}_{\bar{k}} + \mathscr{B}_{\bar{k}}^+ \mathcal{P}_{\bar{k}}^{\mathbf{p}} \mathcal{P}_{[k_1, k_2]}^{n_u} \cdots + \mathscr{B}_{\bar{k}}^{\mathbf{p}} \mathcal{P}_{[k_1, k_2]}^{n_u n_p} \mathcal{P}_{[k_1, k_2]}^{n_u}\right) u_{\bar{k}}, \quad (49)
$$

i.e., $x(k_2)$ can be uniquely expressed from the trajectory $(\text{col}(u_{[k_1,k_2]}, y_{[k_1,k_2]}), p_{[k_1,k_2]})$ given that $\mathscr{O}_{\bar{k}}$ has a left-inverse. From Proposition [2,](#page-9-6) we have that $\mathcal{O}_{\bar{k}}$ is full column rank, i.e., $\mathscr{O}_{\bar{k}}$ has a left-inverse, if and only if $\bar{k} \geq L(\mathfrak{B})$. For $k_1 = 1$ and $k_2 = T_1 + 1$, $x(k_2)$ is the initial condition for the trajectory (w_r, p_r) , which can be uniquely expressed in terms of (w_i, p_i) and^{[6](#page-11-1)} $w(T_i + 1)$, $p(T_i + 1)$ if and only if $\overline{k} = T_i \ge L(\mathfrak{B})$, concluding the proof.

Chris Verhoek received his B.Sc. degree in Mechatronics from the Avans University of Applied Sciences and M.Sc. degree (Cum Laude) in Systems and Control from the Eindhoven University of Technology (TU/e), in 2017 and 2020 respectively. His M.Sc. thesis was selected as best thesis of the Electrical Engineering department in the year 2020. He is currently pursuing a Ph.D. degree under the supervision of Prof. Roland Tóth and dr. Sofie Haesaert at the Control Systems Group, Dept. of Electrical

Engineering, TU/e. In the fall of 2023, he was a visiting researcher at the ETH Zürich, Switzerland. His main research interests include (datadriven) analysis and control of nonlinear and LPV systems and learningfor-control techniques with stability and performance guarantees.

Ivan Markovsky received the Ph.D. degree in electrical engineering from the Katholieke Universiteit Leuven, Leuven, Belgium, in February 2005. He is currently an ICREA Professor with the International Centre for Numerical Methods in Engineering, Barcelona. From 2006 to 2012, he was an Assistant Professor with the School of Electronics and Computer Science, University of Southampton, Southampton, U.K., and from 2012 to 2022, an Associate Professor with the Vrije Universiteit, Brussel, Belgium. His research

interests are computational methods for system theory, identification, and data-driven control in the behavioral setting. Dr. Markovsky was the recipient of an ERC starting grant "Structured low-rank approximation: Theory, algorithms, and applications" 2010-2015, Householder Prize honorable mention 2008, and research mandate by the Vrije Universiteit Brussel research council 2012-2022.

⁶Note that if there is no feed-through, i.e., $D(p) = b_0(p) = 0$, then [\(49\)](#page-11-2) can be expressed in terms of only $(w_{[k_1,k_2-1]}, p_{[k_1,k_2-1]})$.

Sofie Haesaert received the B.Sc. degree cum laude in mechanical engineering and the M.Sc. degree cum laude in systems and control from the Delft University of Technology, Delft, The Netherlands, in 2010 and 2012, respectively, and the Ph.D. degree from Eindhoven University of Technology (TU/e), Eindhoven, The Netherlands, in 2017. She is currently an Assistant Professor with the Control Systems Group, Department of Electrical Engineering, TU/e. From 2017 to 2018, she was a Postdoctoral Scholar

with Caltech. Her research interests are in the identification, verification, and control of cyber-physical systems for temporal logic specifications and performance objectives.

Roland Tóth received his Ph.D. degree with Cum Laude distinction at the Delft Center for Systems and Control (DCSC), Delft University of Technology (TUDelft), Delft, The Netherlands in 2008. He was a Post-Doctoral Research Fellow at TUDelft in 2009 and at the Berkeley Center for Control and Identification, University of California, Berkeley in 2010. He held a position at DCSC, TUDelft in 2011-12. Currently, he is a Full Professor at the Control Systems Group, Eindhoven University of Technology (TU/e) and

a senior researcher at Systems and Control Laboratory, HU-REN Institute for Computer Science and Control in Budapest (SZTAKI), Hungary. He is a Senior Editor of the IEEE Transactions on Control Systems Technology and he was the general chair of the 3rd IFAC Workshop on Linear Parameter-Varying Systems in 2019. Prof. Tóth received the TUDelft Young Researcher Fellowship Award in 2010, the VENI award of The Netherlands Organisation for Scientific Research in 2011 and the Starting Grant of the European Research Council in 2016. He and his research team have participated in several international (FP7, IT2, etc.) and national collaborative research grants. His research interests are in identification and control of linear parameter-varying (LPV) and nonlinear systems, developing machine learning methods with performance and stability guarantees for modeling and control, model predictive control and behavioral system theory. On the application side, his research focuses on advancing reliability and performance of precision mechatronics and autonomous robots/vehicles with LPV and learning-based motion control.
