Abstract—In this paper, we study reconfigurable intelligent surface (RIS)-assisted simultaneous legitimate monitoring and jamming techniques for industrial environments, so that legitimate monitor (LM) and legitimate jammers (LJs) can sustainably monitor and interfere with suspicious communications with minimum transmission power. Specifically, we propose a Block Coordinate Descent-Particle Swarm Optimization (BCD-PSO) based scheme to optimize RIS's phase shift matrix and minimize LJs' transmission power, while successfully jamming and stably monitoring unauthorized communications. Simulation results demonstrate that the proposed BCD-PSO can enhance the performances in terms of monitoring, resource utilization and robustness. Moreover, we effectively exam the best deployment of RIS towards diverse objectives.

Index Terms—Legitimate jamming and monitoring, reconfigurable intelligent surface (RIS), wireless network.

I. INTRODUCTION

RECONFIGURABLE intelligent surface (RIS) is recognized as one of the key technologies towards 6G. By adjusting phases of reflective elements, propagation of electromagnetic waves can be tuned to reshape communications environments. It can not only increase sum rate and optimize resource utilization [1], [2], but also significantly enhance information security [3]. The appealing advantages of RIS have led to extensive researches focused on channel modeling, channel estimation, transmission design, localization techniques, and prototype design, etc, thus resulting in better performance [4].

In recent years, various researches have been developed to tackle malicious attacks, such as channel hopping, power control and adaptive nulling antennas. However, the disadvantages

To overcome shortcomings and enhance information security, RIS have been introduced. The authors of [6] divided RIS for serving legitimate users and interfering illegitimate users, where partition ratio and transmission power were optimized. In [7], a RISassisted scenario against eavesdroppers was considered, and a block coordinate ascent method was adopted to maximize secrecy rate. The authors of [8] applied artificial noise (AN) in RIS-assisted system to degrade eavesdropper's performance while improving secrecy rate. In [5], a RIS-assisted scenario was investigated to minimize transmit power subject to outage probability and signal to interference plus noise ratio (SINR). It also examined that the best deployment of RIS should be close to the base station.

1

While existing researches mainly concentrated on security protection for legitimate users, techniques against unauthorized users recently has been explored [9]–[11]. The authors of [10] proposed an monitoring scheme for illegitimate users with Majorization-Minimization and Alternating Direction Method of Multipliers algorithms. However, it cannot interrupt suspicious communication. In [11], a RIS-assisted eavesdropping and jamming strategy was presented. However, the monitoring and interference cannot be guaranteed simultaneously in this work. To address these shortcomings, we innovatively study the simultaneous legitimate monitoring and jamming techniques to block while intercepting the illegitimate information.

Automated manufacturing processes increasingly rely on wireless technologies that connect sensors, robots and controlling systems, which also bring convenience for illegal users due to the broadcast nature of wireless channel. For example, a suspicious transmitter (ST) delivers manufacturing information to a suspicious receiver (SR). Both ST and SR are hacked, thus system cannot directly turn them off. Therefore, there are urgent needs to develop legitimate monitoring with jamming techniques, to block suspicious communications while identifying what information are being targeted, to strengthen the protection of specific information. Following these objectives, the contributions of this paper are summarized as follows:

 Application Scenario: We present an early research with simultaneous monitoring and jamming suspicious communications in RIS-assisted system for industrial wireless networks, which consists of two illegitimate devices (ST and SR), a collaborative monitoring and jamming system

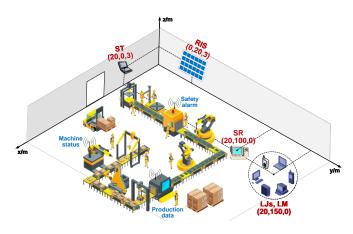

Fig. 1. The model of RIS-assisted legitimate monitoring and jamming system.

(LM and LJs), and a RIS which assists LM and LJs.

- Scheme Design: We propose a Block Coordinate Descent-Particle Swarm Optimization (BCD-PSO) based scheme, which can minimize the transmission power of LJs, jam unauthorized communications, and intercept suspicious information by optimizing RIS's phase shift matrix.
- Performance Enhancement: By using BCD-PSO, LJs and LM can achieve better performances in monitoring, transmission power and robustness. We also effectively exam the best deployment of RIS towards different objectives.

The remainder of the paper is organized as follows. Sections II and III introduce model and problem formulation of RIS-assisted legitimate monitoring and jamming system. Then, we propose BCD-PSO in Section IV. Section V presents simulation results. Finally, the paper concludes in Section VI.

II. SYSTEM MODEL

We consider a RIS-assisted legitimate monitoring and jamming system for industrial environments. As shown in Fig. 1, there is a single-antenna SR and a ST with $M_{\rm t}$ antennas. We deploy a RIS with N elements, assisting a single-antenna LM and K single-antenna LJs. We assume that suspicious communications between ST and SR have been detected. However, both ST and SR are hacked, thus the system cannot turn them off directly. Therefore, LJs send AN to jam SR and meanwhile LM keeps monitoring to identify the targeted information. The channels of ST-to-RIS, RIS-to-SR, LJs-to-RIS, RIS-to-LM, ST-to-LM, ST-to-SR, and LJs-to-SR links are denoted as $\mathbf{H}_{\mathrm{TI}} \in \mathbb{C}^{M_{\mathrm{t}} \times N}$, $\mathbf{h}_{\mathrm{IR}} \in \mathbb{C}^{N \times 1}$, $\mathbf{H}_{\mathrm{KI}} \in \mathbb{C}^{N \times K}$, $\mathbf{h}_{\mathrm{IM}} \in \mathbb{C}^{N \times 1}$, $\mathbf{h}_{\mathrm{TM}} \in \mathbb{C}^{1 \times M_{\mathrm{t}}}$, $\mathbf{h}_{\mathrm{TR}} \in \mathbb{C}^{1 \times M_{\mathrm{t}}}$, and $\mathbf{h}_{\mathrm{KR}} \in$ $\mathbb{C}^{1 \times K}$, respectively, where \mathbb{C} denotes the complex number set. In recent works, there are several channel estimation techniques in RIS-assisted systems [12], [13], based on which we assume that all channel state information (CSI) is known to LJs and LM. The RIS's phase shift matrix is denoted by $\mathbf{\Phi} \triangleq \operatorname{diag}([e^{j\theta_1} e^{j\theta_2} \dots e^{j\theta_N}]),$ where θ_n is the phase shift of the nth element. In addition, due to severe path losses, we ignore signals reflected twice or more by RIS.

III. PROBLEM FORMULATION

In this system, ST uses maximum ratio transmission (MRT) strategy to maximize strength of signal. The LJs also adopt

$$\begin{cases} \mathbf{w}_{\mathrm{ST}} = \frac{\sqrt{P_{\mathrm{ST}}}\mathbf{h}_{\mathrm{TR}}^{\mathrm{H}}}{\|\mathbf{h}_{\mathrm{TR}}^{\mathrm{H}}\|}, \\ \mathbf{w}_{\mathrm{J}} = \frac{\sqrt{P_{\mathrm{J}}(\mathbf{h}_{\mathrm{KR}} + \mathbf{h}_{\mathrm{TR}}^{\mathrm{H}} \mathbf{\Phi} \mathbf{H}_{\mathrm{KI}})}{\|\mathbf{h}_{\mathrm{KR}} + \mathbf{h}_{\mathrm{TR}}^{\mathrm{H}} \mathbf{\Phi} \mathbf{H}_{\mathrm{KI}}\|}. \end{cases}$$
(1)

Here, $P_{\rm ST}$ and $P_{\rm J}$ denote transmission power of ST and LJs, respectively. Considering cooperation between LM and LJs, the impact of AN on LM can be ignored because LM can remove it. Therefore, signals received by SR and LM, denoted by $\mathbf{y}_{\rm SR}$ and $\mathbf{y}_{\rm M}$, respectively, can be written as

LJs, denoted by w_{ST} and w_J , respectively, are given by

$$\begin{cases} \mathbf{y}_{\rm SR} = \mathbf{h}_{\rm s} \mathbf{w}_{\rm ST} x_{\rm ST} + \mathbf{h}_{\rm i} \mathbf{w}_{\rm J}^{\rm H} x_{\rm J} + \mathbf{n}_{\rm SR}, \\ \mathbf{y}_{\rm M} = \mathbf{h}_{\rm m} \mathbf{w}_{\rm ST} x_{\rm ST} + \mathbf{n}_{\rm M}, \end{cases}$$
(2)

where $\mathbf{h}_{s} \triangleq \mathbf{h}_{TR} + \mathbf{h}_{IR}^{H} \boldsymbol{\Phi} \mathbf{H}_{TI}^{H}$, $\mathbf{h}_{i} \triangleq \mathbf{h}_{KR} + \mathbf{h}_{IR}^{H} \boldsymbol{\Phi} \mathbf{H}_{KI}$, and $\mathbf{h}_{m} \triangleq \mathbf{h}_{TM} + \mathbf{h}_{IM}^{H} \boldsymbol{\Phi} \mathbf{H}_{TI}^{H}$. Moreover, x_{ST} and x_{J} are signals transmitted by ST and LJs, respectively, where $\mathbb{E}\{|x_{ST}|^{2}\} = \mathbb{E}\{|x_{J}|^{2}\} = 1$. In addition, $\mathbf{n}_{SR} \sim \mathcal{CN}(0, \sigma_{SR}^{2})$ and $\mathbf{n}_{M} \sim \mathcal{CN}(0, \sigma_{M}^{2})$ both are additive white Gaussian noises. Then, the SINR γ_{SR} of SR and the SNR γ_{M} of LM are given by

$$\begin{cases} \gamma_{\rm SR} = \frac{\|(\mathbf{h}_{\rm TR} + \mathbf{h}_{\rm IR}^{\rm H} \boldsymbol{\Phi} \mathbf{H}_{\rm TI}^{\rm H}) \mathbf{w}_{\rm ST} x_{\rm ST} \|^2}{\|(\mathbf{h}_{\rm KR} + \mathbf{h}_{\rm IR}^{\rm H} \boldsymbol{\Phi} \mathbf{H}_{\rm KI}) \mathbf{w}_{\rm J}^{\rm H} x_{\rm J} \|^2 + \sigma_{\rm SR}^2}, \\ \gamma_{\rm M} = \frac{1}{\sigma_{\rm M}^2} \|(\mathbf{h}_{\rm TM} + \mathbf{h}_{\rm IM}^{\rm H} \boldsymbol{\Phi} \mathbf{H}_{\rm TI}^{\rm H}) \mathbf{w}_{\rm ST} x_{\rm ST} \|^2. \end{cases}$$
(3)

To efficiently jam and intercept the suspicious information, we jointly optimize RIS's phase shift matrix and minimize LJs' transmission power to confine SR's SINR less than a specified threshold $\gamma_{SR,th}$ while maintaining LM's SNR beyond $\gamma_{M,th}$. Therefore, the optimization problem can be formulated as:

$$P1 \min_{\Phi} P_{\rm J} \tag{4}$$

s.t.:
$$\frac{\|(\mathbf{h}_{\mathrm{TR}} + \mathbf{h}_{\mathrm{IR}}^{\mathrm{H}} \boldsymbol{\Phi} \mathbf{H}_{\mathrm{TI}}^{\mathrm{H}}) \mathbf{w}_{\mathrm{ST}}\|^{2}}{\|(\mathbf{h}_{\mathrm{KR}} + \mathbf{h}_{\mathrm{IR}}^{\mathrm{H}} \boldsymbol{\Phi} \mathbf{H}_{\mathrm{KI}}) \mathbf{w}_{\mathrm{I}}^{\mathrm{H}}\|^{2} + \sigma_{\mathrm{SR}}^{2}} \leq \gamma_{\mathrm{SR,th}}; \quad (5)$$

$$\frac{1}{\sigma_{\mathrm{M}}^{2}} \| (\mathbf{h}_{\mathrm{TM}} + \mathbf{h}_{\mathrm{IM}}^{\mathrm{H}} \boldsymbol{\Phi} \mathbf{H}_{\mathrm{TI}}^{\mathrm{H}}) \mathbf{w}_{\mathrm{ST}} \|^{2} \ge \gamma_{\mathrm{M,th}}; \qquad (6)$$

$$_{n}|^{2} = 1, \ n = 1, \dots, N,$$
 (7)

where $v_n = e^{j\theta_n}$. Considering non-convexity of **P1**, the closed-form of optimal solution is intractable. Then, we propose an efficient scheme based on BCD and PSO algorithms.

IV. BLOCK COORDINATE DESCENT-PARTICLE SWARM OPTIMIZATION BASED SCHEME

A. Problem Converting

|v|

We first convert the problem to a manageable form. According to (5), we have

$$P_{\rm J} \ge \frac{\|(\mathbf{h}_{\rm TR} + \mathbf{h}_{\rm IR}^{\rm H} \boldsymbol{\Phi} \mathbf{H}_{\rm TI}^{\rm H}) \mathbf{w}_{\rm ST}\|^2 - \sigma_{\rm SR}^2 \gamma_{\rm SR,th}}{\gamma_{\rm SR,th} \|(\mathbf{h}_{\rm KR} + \mathbf{h}_{\rm IR}^{\rm H} \boldsymbol{\Phi} \mathbf{H}_{\rm KI}) \overline{\mathbf{w}}_{\rm J}^{\rm H}\|^2}, \quad (8)$$

where $\overline{\mathbf{w}}_{J} \triangleq \frac{\mathbf{h}_{KR} + \mathbf{h}_{IR}^{H} \Phi \mathbf{H}_{KI}}{\|\mathbf{h}_{KR} + \mathbf{h}_{IR}^{H} \Phi \mathbf{H}_{KI}\|}$. Clearly, (8) gives a approximate optimum of P_{J} . Next, we aim to minimize the approximate optimum of P_{J} , which can be written as

$$P2 \min_{\Phi} \frac{\|(\mathbf{h}_{\mathrm{TR}} + \mathbf{h}_{\mathrm{IR}}^{\mathrm{H}} \Phi \mathbf{H}_{\mathrm{TI}}^{\mathrm{H}}) \mathbf{w}_{\mathrm{ST}}\|^{2} - \sigma_{\mathrm{SR}}^{2} \gamma_{\mathrm{SR,th}}}{\gamma_{\mathrm{SR,th}} \|(\mathbf{h}_{\mathrm{KR}} + \mathbf{h}_{\mathrm{IR}}^{\mathrm{H}} \Phi \mathbf{H}_{\mathrm{KI}}) \overline{\mathbf{w}}_{\mathrm{J}}^{\mathrm{H}}\|^{2}}$$
(9)
s.t.: (6) and (7). (10)

Algorithm 1 BCD-PSO based scheme

Input: Initialize RIS's phase shift vector $\mathbf{v}^0 = \mathbf{1}_N$; Output: Φ^* , $P_{\rm J}^*$; 1: $r \leftarrow 0$; 2: while convergence condition is not satisfied and r < R do 3: for each RIS's reflective element $\ell \in \{1, 2, \dots, N\}$ do Update $\hat{\theta}_{\ell}^{r+1}$ according to (15); 4: for each particle $k \in \{1, 2, \dots, K\}$ do 5: Initialize $\nu_k(0) = 0, x_k(0) = o_{\text{indiv},k} = o_{\text{group}} =$ 6: $\hat{\theta}_{\ell}^{r+1}, F_{\text{indiv},k} = F_{\text{group}} = \text{Inf};$ 7: end for $t \leftarrow 0;$ 8: 9: while t < T do for each particle $k \in \{1, 2, \ldots, K\}$ do 10: Update $\nu_k(t+1)$, $x_k(t+1)$ and $f_k(t+1)$ according 11: to (17), (16) and (18), respectively; 12: if $f_k(t+1) < F_{\text{indiv},k}$ then $o_{\text{indiv},k} = x_k(t+1), F_{\text{indiv},k} = f_k(t+1);$ 13: end if 14. if $f_k(t+1) < F_{\text{group}}$ then 15: $o_{\text{group}} = x_k(t+1), F_{\text{group}} = f_k(t+1);$ 16: 17: end if end for 18: 19: $t \leftarrow t + 1;$ 20: end while 21: end for 22: $r \leftarrow r + 1;$ 23: end while 24: Calculate Φ^* and $P_{\rm J}^*$ according to $\Phi^* = {\rm diag}(\mathbf{v}^r)$ and (8).

The numerator and denominator of (9) and the left-hand side of (6) can be rewritten as

$$\begin{aligned} \| (\mathbf{h}_{\mathrm{TR}} + \mathbf{h}_{\mathrm{IR}}^{\mathrm{H}} \boldsymbol{\Phi} \mathbf{H}_{\mathrm{TI}}^{\mathrm{H}}) \mathbf{w}_{\mathrm{ST}} \|^{2} &- \sigma_{\mathrm{SR}}^{2} \gamma_{\mathrm{SR,th}} \\ &= \mathbf{v} \mathbf{A}_{\mathrm{ST}} \mathbf{v}^{\mathrm{H}} + \mathbf{v} \mathbf{b}_{\mathrm{ST}} + \mathbf{b}_{\mathrm{ST}}^{\mathrm{H}} \mathbf{v}^{\mathrm{H}} + c_{\mathrm{ST}} - \sigma_{\mathrm{SR}}^{2} \gamma_{\mathrm{SR,th}} \\ &\gamma_{\mathrm{SR,th}} \| (\mathbf{h}_{\mathrm{KR}} + \mathbf{h}_{\mathrm{IR}}^{\mathrm{H}} \boldsymbol{\Phi} \mathbf{H}_{\mathrm{KI}}) \overline{\mathbf{w}}_{\mathrm{J}}^{\mathrm{H}} \|^{2} \\ &= \gamma_{\mathrm{SR,th}} (\mathbf{v} \mathbf{A}_{\mathrm{J}} \mathbf{v}^{\mathrm{H}} + \mathbf{v} \mathbf{b}_{\mathrm{J}} + \mathbf{b}_{\mathrm{J}}^{\mathrm{H}} \mathbf{v}^{\mathrm{H}} + c_{\mathrm{J}}), \\ &\frac{1}{\sigma_{\mathrm{M}}^{2}} \| (\mathbf{h}_{\mathrm{TM}} + \mathbf{h}_{\mathrm{IM}}^{\mathrm{H}} \boldsymbol{\Phi} \mathbf{H}_{\mathrm{TI}}^{\mathrm{H}}) \mathbf{w}_{\mathrm{ST}} \|^{2} \\ &= \frac{1}{\sigma_{\mathrm{M}}^{2}} (\mathbf{v} \mathbf{A}_{\mathrm{M}} \mathbf{v}^{\mathrm{H}} + \mathbf{v} \mathbf{b}_{\mathrm{M}} + \mathbf{b}_{\mathrm{M}}^{\mathrm{H}} \mathbf{v}^{\mathrm{H}} + c_{\mathrm{M}}), \end{aligned}$$

where $\mathbf{v} \triangleq [v_1 \ v_2 \ \dots \ v_N]$, $\mathbf{A}_{\mathrm{ST}} \triangleq \mathbf{a}_{\mathrm{ST}} \mathbf{a}_{\mathrm{ST}}^{\mathrm{H}}$, $\mathbf{a}_{\mathrm{ST}} \triangleq \operatorname{diag}(\mathbf{h}_{\mathrm{IR}}^{\mathrm{H}})\mathbf{H}_{\mathrm{TI}}^{\mathrm{H}}\mathbf{w}_{\mathrm{ST}}$, $\mathbf{b}_{\mathrm{ST}} \triangleq \operatorname{diag}(\mathbf{h}_{\mathrm{IR}}^{\mathrm{H}})\mathbf{H}_{\mathrm{TI}}^{\mathrm{H}}\mathbf{w}_{\mathrm{ST}}\mathbf{w}_{\mathrm{ST}}^{\mathrm{H}}\mathbf{h}_{\mathrm{TR}}^{\mathrm{H}}$, $\mathbf{c}_{\mathrm{ST}} \triangleq \mathbf{h}_{\mathrm{TR}}\mathbf{w}_{\mathrm{ST}}\mathbf{w}_{\mathrm{ST}}^{\mathrm{H}}\mathbf{h}_{\mathrm{TR}}^{\mathrm{H}}$, $\mathbf{A}_{\mathrm{J}} \triangleq \mathbf{a}_{\mathrm{J}}\mathbf{a}_{\mathrm{J}}^{\mathrm{H}}$, $\mathbf{a}_{\mathrm{J}} \triangleq \operatorname{diag}(\mathbf{h}_{\mathrm{IR}}^{\mathrm{H}})\mathbf{H}_{\mathrm{KI}}\mathbf{w}_{\mathrm{J}}^{\mathrm{H}}\mathbf{w}_{\mathrm{J}}$, $\mathbf{b}_{\mathrm{J}} \triangleq \operatorname{diag}(\mathbf{h}_{\mathrm{IR}}^{\mathrm{H}})\mathbf{H}_{\mathrm{KR}}\mathbf{w}_{\mathrm{J}}\mathbf{w}_{\mathrm{J}}\mathbf{h}_{\mathrm{KR}}^{\mathrm{H}}$, $\mathbf{c}_{\mathrm{J}} \triangleq \mathbf{h}_{\mathrm{KR}}\mathbf{w}_{\mathrm{J}}^{\mathrm{H}}\mathbf{w}_{\mathrm{J}}\mathbf{h}_{\mathrm{KR}}^{\mathrm{H}}$, $\mathbf{A}_{\mathrm{M}} \triangleq \mathbf{a}_{\mathrm{M}}\mathbf{a}_{\mathrm{M}}^{\mathrm{H}}$, $\mathbf{a}_{\mathrm{M}} \triangleq \operatorname{diag}(\mathbf{h}_{\mathrm{IM}}^{\mathrm{H}})\mathbf{H}_{\mathrm{TI}}\mathbf{w}_{\mathrm{ST}}\mathbf{w}_{\mathrm{ST}}\mathbf{h}_{\mathrm{TM}}^{\mathrm{H}}$, and $c_{\mathrm{M}} \triangleq \mathbf{h}_{\mathrm{TM}}\mathbf{w}_{\mathrm{ST}}\mathbf{w}_{\mathrm{ST}}^{\mathrm{H}}\mathbf{h}_{\mathrm{TM}}^{\mathrm{H}}$.

B. Procedures of the Proposed BCD-PSO

Next, we apply spirits of BCD and PSO algorithms [14], [15] and tailor them to solve the problem. The proposed BCD-PSO is summarized in Algorithm 1, which is conducted in an iterative fashion. Within each round of iteration, we update each element's phase shift successively. When updating the ℓ th element's phase shift, other elements' phase shifts remain unchanged. Specifically, the update of each phase shift consists of two steps: a *Jamming Optimization* procedure and a *Monitoring Optimization* procedure.

In the *r*th iteration, the RIS's phase shift vector is denoted by $\mathbf{v}^r \triangleq \operatorname{diag}([v_1^r \ v_2^r \ \dots \ v_N^r]), r = 1, 2, \dots, R$, where R is the maximum number of iteration within the BCD-PSO. The optimization problem of updating the ℓ th phase shift is

$$P3 \min_{|v_{\ell}^{r}|^{2}=1} \frac{\operatorname{Re}\{v_{\ell}^{r} \alpha_{\mathrm{ST},\ell}^{r}\} + \beta_{\mathrm{ST},\ell}^{r} - \sigma_{\mathrm{SR}}^{2} \gamma_{\mathrm{SR,th}}}{\gamma_{\mathrm{SR,th}} [\operatorname{Re}\{v_{\ell}^{r} \alpha_{\mathrm{J},\ell}^{r}\} + \beta_{\mathrm{J},\ell}^{r}]}$$
(11)

s.t.:
$$\sigma_{\mathrm{M}}^2 \gamma_{\mathrm{M,th}} - \mathrm{Re}\{v_{\ell}^r \alpha_{\mathrm{M},\ell}^r\} - \beta_{\mathrm{M},\ell}^r \le 0,$$
 (12)

where $\alpha_{\mathrm{X},\ell}^r \triangleq 2(b_{\mathrm{X},\ell} + a_{\mathrm{X},\ell} \sum_{m,m \neq \ell} a_{\mathrm{X},m}^{\mathrm{H}} v_m^{\mathrm{rH}}), \ \beta_{\mathrm{X},\ell}^r \triangleq |a_{\mathrm{X},\ell}|^2 + |\sum_{m,m \neq \ell} v_m^r a_{\mathrm{X},m}|^2 + 2\mathrm{Re}\{\sum_{m,m \neq \ell} v_m^r b_{\mathrm{X},m}\} + c_{\mathrm{X}}, a_{\mathrm{X},m} \ \mathrm{and} \ b_{\mathrm{X},m} \ \mathrm{are the } m\mathrm{th \ elements \ in \ } \mathbf{a}_{\mathrm{X}} \ \mathrm{and} \ \mathbf{b}_{\mathrm{X},m} \ \mathrm{spectively}, \ \mathrm{and \ the \ subscript} \ \mathrm{X} \in \{\mathrm{ST},\mathrm{J},\mathrm{M}\}. \ \mathrm{We \ further \ represent \ these \ complex-valued \ parameters \ with \ the \ amplitudes \ \mathrm{and} \ \mathrm{phases, \ including} \ v_\ell^r = e_{j\theta_\ell^r}^{j\theta_\ell^r}, \ \alpha_{\mathrm{ST},\ell}^r = \rho_{\mathrm{ST},\ell}^r e^{j\theta_{\mathrm{ST},\ell}^r}, \alpha_{\mathrm{J},\ell}^r = \rho_{\mathrm{J},\ell}^r e^{j\theta_{\mathrm{J},\ell}^r}, \ \mathrm{and} \ \alpha_{\mathrm{M},\ell}^r = \rho_{\mathrm{M},\ell}^r e^{j\theta_{\mathrm{M},\ell}^r}. \ \mathrm{Then, \ we \ get} \ P4:$

$$P4 \min_{\substack{0 \le \theta_{\ell}^{r} \le 2\pi}} \frac{\rho_{\mathrm{ST},\ell}^{r} \cos(\theta_{\ell}^{r} + \theta_{\mathrm{ST},\ell}^{r}) + \beta_{\mathrm{ST},\ell}^{r} - \sigma_{\mathrm{SR}}^{2} \gamma_{\mathrm{SR,th}}}{\gamma_{\mathrm{SR,th}} [\rho_{\mathrm{J},\ell}^{r} \cos(\theta_{\ell}^{r} + \theta_{\mathrm{J},\ell}^{r}) + \beta_{\mathrm{J},\ell}^{r}]} \quad (13)$$

s.t.: $\sigma_{\mathrm{M}}^{2} \gamma_{\mathrm{M,th}} - \rho_{\mathrm{M},\ell}^{r} \cos(\theta_{\ell}^{r} + \theta_{\mathrm{M},\ell}^{r}) - \beta_{\mathrm{M},\ell}^{r} \le 0. \quad (14)$

The BCD-PSO scheme are then detailed as follows.

1) Jamming Optimization

Based on (13), there is a finite number of extremums within $[0, 2\pi]$. Taking the derivative of (13) with respect to θ_{ℓ}^r and letting it be 0, we get $B^r + C^r \sin(\theta_{\ell}^r + \psi_{\ell}^r) = 0$, where $B^r \triangleq \gamma_{\mathrm{SR,th}} \rho_{\mathrm{ST},\ell}^r \rho_{\mathrm{J},\ell}^r \sin(\theta_{\mathrm{J},\ell}^r - \theta_{\mathrm{ST},\ell}^r)$, $C^r \triangleq \sqrt{p^{r_2} + q^{r_2} - 2p^r q^r \cos(\theta_{\mathrm{ST},\ell}^r - \theta_{\mathrm{J},\ell}^r)}$, $\psi_{\ell}^r \triangleq \arctan(\frac{p^r \sin(\theta_{\mathrm{J},\ell}^r) - q^r \sin(\theta_{\mathrm{ST},\ell}^r)}{p^r \cos(\theta_{\mathrm{J},\ell}^r) - q^r \cos(\theta_{\mathrm{ST},\ell}^r)})$ with $p^{r_2} \triangleq \gamma_{\mathrm{SR,th}} \rho_{\mathrm{J},\ell}^r (\beta_{\mathrm{ST},\ell}^r - \sigma_{\mathrm{SR}}^2 \gamma_{\mathrm{SR,th}})$ and $q^{r_2} \triangleq \rho_{\mathrm{ST},\ell}^r \beta_{\mathrm{J},\ell}^r$. Then, we have

$$\begin{cases} \theta_{\ell,1}^{r+1} = \arcsin\left(\frac{B^r}{C^r}\right) - \psi_{\ell}^r, \\ \theta_{\ell,2}^{r+1} = \pi - \arcsin\left(\frac{B^r}{C^r}\right) - \psi_{\ell}^r. \end{cases}$$
(15)

Then, we substitute $\theta_{\ell,1}^{r+1}$ and $\theta_{\ell,2}^{r+1}$ into (13), respectively, and set a solution $\hat{\theta}_{\ell}^{r+1}$ equal to the one with smaller objective.

2) Monitoring Optimization

Next, we use PSO to search for a better solution. We first initializes K particles. The kth particle, k = 1, 2, ..., K, is characterized by the iteratively updated position, velocity and fitness, denoted by $x_k(t)$, $\nu_k(t)$ and $f_k(t)$, respectively, where t denotes the t-th iteration, t = 1, 2, ..., T, and T is the maximum number of iteration. We define the position as element's phase shift. All particles will evolve differently under random rules, such that better solution can be discovered.

Specifically, the position's update is given by

$$x_k(t+1) = x_k(t) + \nu_k(t+1), \tag{16}$$

where $\nu_k(t)$ is the *k*th particle's updated velocity at the *t*-th iteration. Correspondingly, the velocity is obtained by

$$\nu_k(t+1) = w(t)\nu_k(t) + c_1r_1(t)[o_{\text{indiv},k} - x_k(t)] + c_2r_2(t)[o_{\text{group}} - x_k(t)],$$
(17)

where w(t) is the inertia weight at the *t*-th iteration, to dampen the velocity. Lower inertia weight confines the search within a relatively local range, and vice verse. To effectively attain the convergence, we let w(t) decrease as *t* increases, where $w(t) = w_{\max} - (\frac{w_{\max} - w_{\min}}{T})t$, with the pre-set upper limit w_{\max} and lower limit w_{\min} . Here, $o_{\text{indiv},k}$ and o_{group} represent current optimized individual and group positions, c_1 and c_2 are individual and group learning coefficients that control the influence of $o_{\text{indiv},k}$ and o_{group} , respectively, and $r_1(t)$ and $r_2(t)$ both are uniformly-distributed random numbers within [0, 1] to generate difference across evolvement of each particle.

In PSO algorithm, fitness is calculated after updating position. We define fitness according to Eqs. (13) and (14) as

$$f_k(t+1) = \frac{\rho_{\mathrm{ST},\ell}^r \cos(x_k(t+1) + \theta_{\mathrm{ST},\ell}^r) + \beta_{\mathrm{ST},\ell}^r - \sigma_{\mathrm{SR}}^2 \gamma_{\mathrm{SR,th}}}{\gamma_{\mathrm{SR,th}} [\rho_{\mathrm{J},\ell}^r \cos(x_k(t+1) + \theta_{\mathrm{J},\ell}^r) + \beta_{\mathrm{J},\ell}^r]} + \Xi \{\sigma_{\mathrm{M}}^2 \gamma_{\mathrm{M,th}} - \rho_{\mathrm{M},\ell}^r \cos(x_k(t+1) + \theta_{\mathrm{M},\ell}^r) - \beta_{\mathrm{M},\ell}^r \le 0\},$$
(18)

where $\Xi\{L\} \triangleq (1-L)c_{\rm p}, L \in \{0,1\}$ is a bool variable, and $c_{\rm p}$ is a large positive value for violating (14). Moreover, the optimized fitnesses corresponding to $o_{{\rm indiv},k}$ and $o_{{\rm group}}$ are denoted by $F_{{\rm indiv},k}$ and $F_{{\rm group}}$, respectively. If $f_k(t+1) < F_{{\rm indiv},k}$, the $x_k(t+1)$ will be set to $o_{{\rm indiv},k}$. Furthermore, if $f_k(t+1) < F_{{\rm group}}$, update the $o_{{\rm group}}$ by $x_k(t+1)$.

Then, we iteratively update phase shift of each element in sequence until the maximum number is reached or the convergence condition ($\epsilon = \frac{\sum_{n=1}^{N} ||\mathbf{v}_n^{r+1} - \mathbf{v}_n^r||}{\sum_{n=1}^{N} ||\mathbf{v}_n^r||} \le \epsilon_{\text{th}}$) is triggered, where ϵ_{th} is the specified threshold. According to the above steps, we can get the suboptimal solution of RIS's phase shift matrix Φ^* and LJs's transmission power P_J^* , respectively.

V. SIMULATION EVALUATIONS

In this section, we present simulation results to evaluate performances of our proposed BCD-PSO based scheme. All results are averaged over 200 independent simulations, and the simulation parameters are given below unless otherwise stated.

We configure a three-dimensional coordinate as shown in Fig. 1, where RIS is placed at (0, 20, 3) (unit: m). ST and SR are located at (20, 0, 3) and (20, 100, 0), respectively. LM and LJs are randomly distributed in the area centered at (20, 150, 0) with a radius of 20 m. We assume that \mathbf{h}_{TR} , \mathbf{h}_{TM} , and \mathbf{h}_{KR} follow the Rayleigh-fading, and RIS-related links follow the Rician fading. Rician factors of H_{TI} and h_{IR} both are 2 due to obstacles, and Rician factors of $h_{\rm IM}$ and \mathbf{H}_{KI} both equal to 10. The large-scale path loss is modeled by $PL = PL_0 - 10\mu \log(\frac{d}{d_0})$, where PL_0 is the path loss at reference distance $d_0 = 1$ m, and μ is the path loss factor. Due to scatters, path loss factors of $\mathbf{h}_{\mathrm{TR}},\,\mathbf{h}_{\mathrm{IR}},\,\mathbf{h}_{\mathrm{KR}},$ and \mathbf{h}_{TM} are 4, and path loss factors of \mathbf{H}_{TI} , \mathbf{H}_{KI} , and \mathbf{h}_{IM} are set to 2 with the selection of RIS's location. The noise power at SR and LM both are -90~dBm. Moreover, $\gamma_{\rm M,th}$ equal to 12~dB, $\epsilon_{\rm th}$ is 0.01, $w_{\rm min}$ and $w_{\rm max}$ are set to 0 and 2π , respectively, and iteration numbers R and T are 50 and 80, respectively.

To demonstrate performance improvement achieved by the proposed BCD-PSO, we define successfully monitoring probability (SMP) and successfully jamming probability (SJP) as the proportion of successfully monitoring and jamming on suspicious communications in simulations, respectively. Moreover, we consider the following comparative schemes:

- *PSO Scheme*: Only PSO-based monitoring optimization procedure is adopted, and initial positions of particles are randomly selected within $[0, 2\pi]$.
- Simulated Annealing (SA) Scheme: Compared to the PSO Scheme, SA algorithm [16] is used to optimize Φ and P_J.

- *PSO-Domain Scheme*: Compared to *PSO Scheme*, initial positions of particles are randomly selected within the feasible domains given by (14).
- *BCD-Domain Scheme*: Only the BCD-based jamming optimization procedure is employed under the feasible domains given by (14).
- BCD-SA Scheme: It uses BCD-based jamming optimization procedure and adopts SA algorithm in monitoring optimization procedure.
- *Random Phase*: The phase shift of each RIS's reflective element is independently generated from 0 to 2π .
- *Without RIS*: There is no RIS in the system, which means that all CSI for RIS-related links are set to zero matrices.

In Fig. 2, we study the effect of ST's transmission power on LJs' transmission power, SJP and SMP. It can be observed from Figs. 2(a) and (b) that the proposed BCD-PSO achieve the lowest transmission power while attaining 100%SJP, indicating completely block suspicious communications. The BCD-PSO also obtains the highest SMP according to Fig. 2(c). By comparison, other schemes cannot simultaneously minimize LJs' transmission power and monitor suspicious communications. For example, the BCD-Domain has similar performance in resource utilization to the BCD-PSO, but its monitoring performance is much worse; the PSO can achieve similar SMP to the proposed BCD-PSO, but LJs would consume more transmission power; and both Random Phase and Without RIS cannot realize effective monitoring and resource saving. Moreover, as ST's transmission power increases, LJs need more power and LM's monitoring performance gets better.

Fig. 3 shows variations of LJs' transmission power and SMP with RIS's location and the number of elements in the case of 100% SJP. From the results, transmission power of LJs decreases with the smaller distance between RIS and SR, while SMP increases with decrement of the distance between RIS and LM. Therefore, the preferred location of RIS is between SR and LM, that is, RIS's Y-coordinate should be confined within [100, 150] under the environment set for simulations. It can also be observed that LJs' transmission power decreases and SMP increases when the number of elements gets larger, which demonstrates the crucial role the RIS plays. Furthermore, compared among the BCD-PSO, PSO and BCD-Domain schemes, the PSO tends to optimize monitoring performance, the BCD-Domain tends to reduce LJs' transmission power, and the proposed BCD-PSO can achieve better performances in both terms of monitoring and resource utilization.

As shown in Fig. 4, we compare the average SNR of LM with the SMP under different schemes. It is noted that LM's SNR obtained by the BCD-PSO is not the highest one. However, the BCD-PSO can attain the highest SMP among comparative schemes, with completely near-100% SMP. The results above indicate that the BCD-PSO is more robust to uncertainties in wireless communications environment.

VI. CONCLUSIONS

In this paper, a RIS-assisted legitimate monitoring and jamming system towards industrial environment was studied,

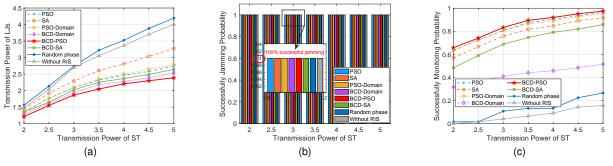

Fig. 2. Performances versus ST's transmission power with K = 6, N = 10, and $\gamma_{SR,th} = -10$ dB. (a) LJs' transmission power. (b) SJP. (c) SMP.

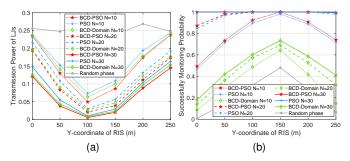

Fig. 3. Performances versus Y-coordinate of RIS with K = 8, $\gamma_{\text{SR,th}} = -10$ dB, and $P_{\text{ST}} = 1$. (a) LJs' transmission power. (b) SMP.

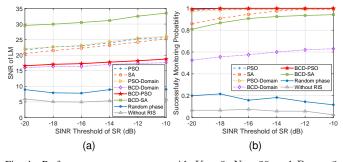

Fig. 4. Performances versus $\gamma_{\text{SR,th}}$ with K = 6, N = 20, and $P_{\text{ST}} = 3$. (a) SNR of LM. (b) SMP.

in which LM and LJs conduct legitimate monitoring and jamming on suspicious communications, respectively. To minimize the transmission power of LJs while preventing SR from successful decoding and ensuring continuous monitoring, we proposed a robust BCD-PSO based scheme. We sequentially updated phase shift of each reflective elements and took results of the *Jamming Optimization* procedure as initial values of the *Monitoring Optimization* procedure. Simulation results showed that our proposed BCD-PSO is able to achieve better performances in terms of LJs' transmission power, SMP and robustness. We can also effectively optimize the deployment of RIS towards different objectives.
