(Dated: December 30, 2024)

We propose a (1+1)D lattice model, inspired by a weak Hopf algebra generalization of the cluster state model, which realizes Haagerup fusion category  $\mathcal{H}_3$  symmetry and features a tensor product Hilbert space. The construction begins with a reconstruction of the Haagerup weak Hopf algebra *H*<sup>3</sup> from the Haagerup fusion category, ensuring that the representation category of  $H_3$  is equivalent to  $H_3$ . Utilizing the framework of symmetry topological field theory (SymTFT), we develop an ultra-thin weak Hopf quantum double model, characterized by a smooth topological boundary condition. We show that this model supports Haagerup fusion category symmetry. Finally, we solve the ground state of the model in terms of a weak Hopf matrix product state, which serves as a natural generalization of the cluster state, embodying Haagerup fusion category symmetry.

*Introduction.* — Symmetry is one of the central topics in physics and is traditionally characterized by a group. From a modern perspective, symmetries are characterized by the algebraic structure of topological defects [\[1–](#page-5-0)[16\]](#page-6-0). Symmetries associated with non-invertible topological defects are known as non-invertible symmetries. For an  $(n+1)$ -dimensional system, the symmetries are described by fusion *n*-categories [\[3,](#page-5-1) [17\]](#page-6-1). For (1+1)-dimensional systems, these symmetries are described by fusion 1-categories  $C$ , i.e., the usual fusion categories; hence, they are also referred to as fusion category symmetries [\[15,](#page-6-2) [16,](#page-6-0) [18\]](#page-6-3).

The topological defect lines (TDLs) for (1+1)D system are labeled by the simple objects in C, and these TDLs can be fused according to the fusion rule:

$$
a \otimes b = \sum_{c \in \text{Irr}(\mathcal{C})} N_{ab}^c c,\tag{1}
$$

where  $N_{ab}^c$  are non-negative integers known as fusion multiplicities. The associativity of the fusion is characterized by *F*-symbols. Group symmetry is a special case where the fusion category is chosen as Vect*G*, the category of *G*-graded vector spaces [\[19\]](#page-6-4).

Non-invertible symmetries also play a crucial role in conformal field theory (CFT), particularly in the investigation of its properties and classification. In the case of rational CFTs (RCFTs), which form the foundational building blocks of general CFTs, the underlying mathematical structure is identified as modular tensor categories (MTCs) [\[20\]](#page-6-5). An important open question is whether a corresponding CFT can be constructed for any given MTC. It has been proposed that subfactors can be used to construct CFTs, with a conjectured correspondence between subfactors and CFTs [\[21–](#page-6-6)[25\]](#page-6-7). While there is significant evidence supporting this conjecture, several potential counterexamples exist, one of the most notable being the Haagerup subfactor [\[26](#page-6-8)[–28\]](#page-6-9). There are three fusion categories arising from Haagerup subfactors, namely  $\mathcal{H}_1$ ,  $\mathcal{H}_2$ , and  $H_3$ , each of which is Morita equivalent to the others. Recently, there has been considerable interest in constructing lattice models that exhibit Haagerup  $\mathcal{H}_3$  symmetry [\[29–](#page-6-10)[34\]](#page-6-11). The

Haagerup fusion category  $H_3$  [\[35,](#page-6-12) [36\]](#page-6-13) has a Drinfeld center  $\mathcal{Z}(\mathcal{H}_3)$  that is a modular tensor category (MTC).

Given that any unitary (multi)fusion category corresponds to the representation category  $\text{Rep}(H)$  of some weak Hopf algebra *H*, it is a natural progression to examine non-invertible symmetries within the framework of Hopf and weak Hopf algebras [\[37–](#page-6-14)[44\]](#page-6-15). These symmetries, which are associated with structures such as Hopf, quasi-Hopf, and weak Hopf algebras, along with their module and comodule algebras, represent a substantial class of non-invertible symmetries [\[4,](#page-5-2) [45–](#page-6-16)[50\]](#page-6-17).

In this work, we introduce a  $(1+1)D$  lattice model, inspired by a weak Hopf algebra generalization of the cluster state model. This model realizes the Haagerup fusion category  $\mathcal{H}_3$  symmetry and is constructed with a tensor product Hilbert

<span id="page-0-1"></span>FIG. 1. Illustration of SymTFT sandwich and cluster ladder model. (a) The symmetry TFT consists of a symmetry boundary  $B_{sym}$  which encodes the fusion category symmetry; a physical boundary, which may be gapped or gapless that encodes the dynamics of the theory; the bulk is a topological field theory  $\mathcal{Z}(\mathcal{B}_{sym})$ . (b) Depiction of the cluster ladder model, which is an ultra-thin quantum double model with two boundaries (the qudit is put on edges), one boundary is chosen as a smooth boundary that encodes the symmetry information. If the physical boundary is chosen as a rough boundary, then the model becomes a cluster state model. (c) The chessboard representation of the cluster ladder model, where the qudits are placed on vertices, and each vertex corresponds to an edge of the quantum double model. For the cluster state model, the vertices on the physical boundary (cyan vertices) are removed, leaving only two types of local stabilizers: one for the symmetry boundary vertex operator and the other for the face operator.

<span id="page-0-0"></span><sup>∗</sup> [giannjia@foxmail.com](mailto:giannjia@foxmail.com)

space, distinguishing it significantly from models constructed using anyonic chains [\[30](#page-6-18)[–33\]](#page-6-19).

The one-dimensional cluster state model is a quintessential example of an symmetry-protected topological (SPT) phase, exhibiting  $\mathbb{Z}_2 \times \mathbb{Z}_2$  SPT order [\[51\]](#page-6-20). More recently, it has been proposed that the cluster state also hosts a noninvertible global symmetry, described by the fusion category  $Rep(D_8)$  [\[52\]](#page-7-0). Generalizations to finite groups are discussed in Refs. [\[53,](#page-7-1) [54\]](#page-7-2). The Hopf algebraic generalization is pre-sented in Ref. [\[55\]](#page-7-3), where it is shown that the cluster state model is, in fact, an ultra-thin quantum double model with one smooth boundary and one rough boundary. In a recent work [\[56\]](#page-7-4), we develop a general theory for the weak Hopf cluster state model, which can realize arbitrary weak Hopf symmetries (with fusion category symmetry as a special case). Building on these insights, we introduce a lattice model that exhibits Haagerup fusion category symmetry (and, more generally, Haagerup weak Hopf symmetry). The main result can be summarized as follows:

<span id="page-1-3"></span>Theorem 1. *By applying the Tannaka-Krein reconstruction or the boundary tube algebra approach, we can recover a C*<sup>∗</sup> *weak Hopf algebra H*3*, whose representation category* Rep(*H*3) *is equivalent to the Haagerup fusion category* H<sup>3</sup> *as fusion categories. When H*<sup>3</sup> *is used as input data for a weak Hopf cluster state model (or, more generally, a cluster ladder model) as described in Ref. [\[56\]](#page-7-4), we obtain a cluster model that exhibits Haagerup* H<sup>3</sup> *symmetry (see Eq.* [\(23\)](#page-4-0)*) and, more generally, weak Hopf symmetry H*ˆ <sup>3</sup> *(the dual weak Hopf algebra of H<sub>3</sub>*).

*The Haagerup fusion category symmetric cluster state*  $\textit{model} \ \mathbb{H}_{\text{cluster}} = -\sum_{v_s} \mathbb{A}_{v_s} - \sum_f \mathbb{B}_f \ \textit{possesses the follow-}$ *ing weak Hopf symmetry:*

- *On a closed manifold:* Sym =  $Cocom(\hat{H}_3) \times$  $Cocom(H_3)$ *, where*  $Cocom(H)$  *is the set of all cocommutative elements in weak Hopf algebra H.*
- *On an open manifold:*  $Sym = \hat{H}_3 \times H_3$ .

*Note that*  $H_3 \simeq \text{Rep}(H_3) \subset \text{Cocom}(\hat{H}_3) \subset \hat{H}_3$  (here we *focus on the fusion algebra of the category), implying that both cases exhibit*  $H_3$  *symmetry.* 

*Haagerup Fusion Category* H<sup>3</sup> *Symmetry.* — The Haagerup fusion category is one of the simplest examples that does not originate from finite groups or affine Lie algebras.

The category  $\mathcal{H}_3$  contains six simple objects: 1,  $\alpha$ ,  $\alpha^2$ ,  $\rho$ ,  $\alpha \rho$ ,  $\alpha^2 \rho$ . The fusion rules are summarized in Table [I,](#page-1-0) with the nontrivial rules given by:

<span id="page-1-1"></span>
$$
\alpha^3 = 1, \quad \alpha \rho = \alpha \otimes \rho, \quad \alpha^2 \rho = \alpha^2 \otimes \rho, \n\rho \otimes \alpha = \alpha^2 \rho, \quad \rho \otimes \alpha^2 = \alpha \rho, \n\rho \otimes \rho = 1 \oplus \rho \oplus \alpha \rho \oplus \alpha^2 \rho.
$$
\n(2)

All other fusion rules can be derived from Eq. [\(2\)](#page-1-1). The quantum dimensions of the simple objects are  $d_1 = d_\alpha = d_{\alpha^2} = 1$ and  $d_{\rho} = d_{\alpha \rho} = d_{\alpha^2} \rho = \frac{3 + \sqrt{13}}{2}$ . The *F*-symbols of  $\mathcal{H}_3$  have been computed in Refs. [\[57,](#page-7-5) [58\]](#page-7-6).

<span id="page-1-0"></span>TABLE I. Fusion rule for the Haagerup fusion category  $\mathcal{H}_3$ . In this table, the elements of the first column are fused with the elements of the first row ("column labels"  $\otimes$  "row labels").

⊗		$\alpha$	$\alpha$	o	$\alpha$ $\rho$	$\alpha^2$ P
		$\alpha$	$\alpha^2$	D	$\alpha$ $\rho$	$\alpha^2$ P
$\alpha$	$\alpha$	$\alpha^2$		$\alpha$ $\rho$	$\alpha^2$ $\rho$	ρ
$\alpha^2$	$\alpha^2$		$\alpha$	$\alpha^2$ $\rho$	ρ	$\alpha$ $\rho$
$\rho$	$\mathcal{D}$	$\alpha^2$ $\rho$	$\alpha$ $\rho$	$1 \oplus \rho \oplus \alpha \rho \oplus \alpha^2 \rho$	$\alpha^2 \oplus \rho \oplus \alpha \rho \oplus \alpha^2 \rho \, \vert \, \alpha \oplus \rho \oplus \alpha \rho \oplus \alpha^2 \rho$	
$\alpha$ $\rho$	$\alpha$ $\rho$	$\rho$	$\alpha^2$ $\rho$	$\alpha \oplus \rho \oplus \alpha \rho \oplus \alpha^2 \rho$	$1 \oplus \rho \oplus \alpha \rho \oplus \alpha^2 \rho$	$\alpha^2 \oplus \rho \oplus \alpha \rho \oplus \alpha^2 \rho$
$\alpha^2 \rho \alpha^2 \rho \alpha \rho$			$\overline{\rho}$	$\boxed{\alpha^2 \oplus \rho \oplus \alpha \rho \oplus \alpha^2 \rho \, \boxed{\alpha \oplus \rho \oplus \alpha \rho \oplus \alpha^2 \rho}}$		$1 \oplus \rho \oplus \alpha \rho \oplus \alpha^2 \rho$

The Drinfeld center  $\mathcal{Z}(\mathcal{H}_3)$  is a MTC containing 12 simple objects (topological charges). These simple objects are written as  $(X, \beta_{X,\bullet})$ , where *X* is a simple object in  $\mathcal{H}_3$ , and  $\beta_{X,\bullet}$  denotes the half-braiding. Following Ref. [\[59\]](#page-7-7), we denote these topological charges as  $1_{\mathcal{Z}(\mathcal{H}_3)}$ ,  $\pi_{1,2}$ ,  $\sigma_{1,2,3}$ ,  $\mu_{1,2,\dots,6}$ . The quantum dimensions and topological spins of these topological charges are listed in Table [II.](#page-1-2) The quantum dimension of  $\mathcal{Z}(\mathcal{H}_3)$  is

$$
\dim(\mathcal{Z}(\mathcal{H}_3)) = \sum_{a \in \text{Irr}(\mathcal{Z}(\mathcal{H}_3))} d_a^2 = 99d_\rho^2 + 54d_\rho + 18. \tag{3}
$$

The S-matrix is given in Ref. [\[59,](#page-7-7) Section 2.2].

*Reconstructing weak Hopf H*<sup>3</sup> *symmetry from Haagerup fusion category*  $H_3$  *symmetry.* — Our model is based on the weak Hopf algebra  $H_3$  for which  $H_3$  is equivalent to Rep( $H_3$ ). By definition, a complex weak Hopf algebra [\[60\]](#page-7-8) is a complex vector space *H* equipped with algebra  $(H, \mu, \eta)$  and coalgebra  $(H, \Delta, \varepsilon)$  structures, along with an antipode map  $S: H \to H$ , satisfying specific compatibility conditions. We use Sweedler's notation for comultiplication, denoting ∆(*h*) =  $\sum_{(h)}h^{(1)}\otimes h^{(2)}:=\sum_i h^{(1)}_i\otimes h^{(2)}_i$  $i^{(2)}$ . The comultiplication satisfies  $\Delta(xy) = \Delta(x) \cdot \Delta(y)$ , explicitly expressed as  $\sum_{(xy)} (xy)^{(1)} \otimes$  $(xy)^{(2)} = \sum_{(x),(y)} x^{(1)} \cdot y^{(1)} \otimes x^{(2)} \cdot y^{(2)}$ . The unit satisfies weak comultiplicativity,  $(\Delta \otimes id) \circ \Delta(1_H) = (\Delta(1_H) \otimes 1_H) \cdot (1_H \otimes$  $\Delta(1_H)$ ), where  $\Delta(1_H) = \sum_{(1_H)} 1_H^{(1)} ⊗ 1_H^{(2)}$  $H^{(2)}$ . The counit satisfies weak multiplicativity, meaning that for all  $x, y, z \in H$ ,  $\mathcal{E}(xyz) = \sum_{(y)} \mathcal{E}(xy^{(1)}) \mathcal{E}(y^{(2)}z)$ . The antipode *S* satisfies three

key properties. For the left counit,  $\sum_{(x)} x^{(1)} S(x^{(2)}) = \varepsilon_L(x) :=$  $\sum_{(1_H)}\pmb{\varepsilon}(1_H^{(1)})$  $_{H}^{(1)}(x)1_{H}^{(2)}$  $H^{(2)}$ . For the right counit,  $\sum_{(x)} S(x^{(1)}) x^{(2)} =$  $\varepsilon_R(x) := \sum_{(1_H)} 1_H^{(1)}$ *H* ε(*x*1 (2)  $\binom{2}{H}$ . Additionally, the antipode satisfies the decomposition property,  $\sum_{(x)} S(x^{(1)}) x^{(2)} S(x^{(3)}) =$ *S*(*x*).

The images of the left and right counit maps,  $H_L = \varepsilon_L(H)$ and  $H_R = \varepsilon_R(H)$ , serve as the tensor unit in the representation category  $\text{Rep}(H)$ , which is typically a multifusion category. If *H* is both connected [\[61\]](#page-7-9) (also known as pure in [\[60\]](#page-7-8)) and coconnected  $[62]$ , then Rep(*H*) is a fusion category. For more information on weak Hopf algebras and their applications to lattice models, refer to Refs. [\[43,](#page-6-21) [56\]](#page-7-4).

The Tannaka-Krein reconstruction offers a structured approach to obtaining a weak Hopf algebra from a fusion category. For any fusion category C, there exists a **C**-algebra A such that C can be faithfully and exactly embedded into  $A \text{Mod}_A$  via a monoidal functor  $F : \mathcal{C} \to A \text{Mod}_A$ . The algebra  $H = \text{End}(F)$ , defined by the natural transformations of *F*, forms a weak Hopf algebra. Furthermore, the representation category  $\text{Rep}(H)$  is equivalent to C as a unitary fusion category [\[63,](#page-7-11) [64\]](#page-7-12). When applied to  $\mathcal{H}_3$ , this process yields a weak Hopf algebra, denoted  $H_3$ , such that  $\mathcal{H}_3 \simeq \text{Rep}(H_3)$ . The weak Hopf algebras whose representation categories are equivalent to  $\mathcal{H}_3$  are not unique; they are Morita equivalent to one another. We will call *H*<sup>3</sup> Haagerup weak Hopf algebra.

An intuitive and explicit approach involves the concept of the boundary tube algebra [\[44,](#page-6-15) [65](#page-7-13)[–67\]](#page-7-14), as applied to the string-net model, where the basis elements and Haar integral can be explicitly written. For a given bulk fusion category C, we consider a gapped boundary described by a C-module category  $e^{i\theta}$  and construct the corresponding boundary tube algebra  $\text{Tube}(\mathcal{eM})$ , which is a  $C^*$  weak Hopf algebra. Setting  $M = C$ , i.e., considering the smooth boundary, we obtain the boundary tube algebra spanned by the following basis:

<span id="page-2-0"></span>
$$
\begin{cases}\n\begin{cases}\ng \\
\frac{\lambda}{\mu} \\
e \\
\frac{\lambda}{\mu} \\
e\n\end{cases} & a, c, e, f, g \in \text{Irr}(\mathcal{C}), \\
\mu \in \text{Hom}(a \otimes f, g), \\
v \in \text{Hom}(c, a \otimes e) \\
c\n\end{cases}
$$
\n(4)

The unit is give by

which means we set  $a = 1$  and  $c = e$ ,  $f = g$  and  $\mu = id$ ,  $v = id$ 

in Eq. [\(4\)](#page-2-0). The multiplication is defined as

After evaluating the diagram on the right-hand side using *F*moves, parallel moves, and loop moves [\[44\]](#page-6-15), we obtain a linear combination of the basis elements in Eq. [\(4\)](#page-2-0). The counit is given by

After performing the topological evaluation of the right-hand side, the result will be a real number. The comultiplication is defined as

The antipode map is defined as

It can be proved that this is a  $C^*$  weak Hopf algebra [\[44\]](#page-6-15). The Haar integral is of the form:

<span id="page-2-1"></span>
$$
\lambda = \frac{1}{\text{rank } \mathcal{C}} \frac{1}{\text{FPdim}(\mathcal{C})} \sum_{a, x, y, \mu} \sqrt{\frac{d_a}{d_x^3 d_y}} a \begin{pmatrix} y \\ x \\ x \\ x \end{pmatrix}
$$
 (10)

A detailed proof will be provided in Ref. [\[67\]](#page-7-14). Since the dual weak Hopf algebra can be regarded as a  $\mathbf{Tube}(\mathcal{C}_{\mathcal{C}})$ , the Haar measure  $\Lambda$  (Haar integral of the dual weak Hopf algebra) can be constructed similarly (see also Ref. [\[66\]](#page-7-15) for a slightly different construction, where the structure constants of the boundary tube algebra are chosen differently, although the two algebras remain Morita equivalent).

The fusion category  $\mathcal{C} = \text{Fun}_{\mathcal{C}}(\mathcal{C}, \mathcal{C})$ (the category of module category functors), interpreted as the boundary phase, can be embedded into the representation category of the tube algebra Rep(Tube( $_{\mathcal{C}}(\mathcal{C})$ ). It is believed that  $\mathcal{C} \simeq$  Rep(Tube( $_{\mathcal{C}}(\mathcal{C})$ )  $[65, 66]$  $[65, 66]$  $[65, 66]$ , and we will argue in Ref.  $[67]$  that this is, in fact, an embedding  $\mathcal{C} \hookrightarrow \text{Rep}(\text{Tube}(\mathcal{C}))$  for general case. Consequently, the fusion category  $\mathcal{C}_{\mathcal{M}}^{\vee} := \text{Fun}_{\mathcal{C}}(\mathcal{M},\mathcal{M})$  can be realized through the weak Hopf algebra  $\mathbf{Tube}(\rho \mathcal{C})$ . For further details, we refer the reader to Refs. [\[44,](#page-6-15) [67\]](#page-7-14). When applied to  $\mathcal{H}_3$ , we denote the corresponding tube algebra as  $H_3 = \textbf{Tube}(\mathcal{H}_3 \mathcal{H}_3)$ , with a slight abuse of notation.

*Symmetry Topological Field Theory (SymTFT) with Haagerup*  $H_3$  *symmetry.* — SymTFT provides a general framework for studying non-invertible symmetry-protected topological (SPT) phases in both gapped and gapless cases (see, e.g., [\[3](#page-5-1)[–13\]](#page-6-22)). The SymTFT can be applied to weak Hopf lattice gauge theory and establish the general algebraic framework for  $(1+1)$ D non-invertible SPT phases [\[55,](#page-7-3) [56\]](#page-7-4). Based on this, we will construct a lattice model.

The SymTFT has a sandwich structure, as illustrated in Fig. [1](#page-0-1) (a). The sandwich manifold is defined as  $\mathbb{M}^{1,1} \times [0,1]$ , where  $\mathbb{M}^{1,1}$  represents the  $(1 + 1)$ -dimensional manifold on which our system resides. This manifold has two boundaries: the basic idea is to impose non-invertible symmetry on one boundary and place the physical system on the other. After compactifying over the interval [0,1], we obtain a  $(1 + 1)$ dimensional system with non-invertible symmetry. To construct the SymTFT, the symmetry boundary must be chosen as a gapped topological boundary condition. There are many topological orders that do not have any gapped boundary, but non-chiral topological orders are guaranteed to have at least one gapped boundary. Thus, we put a non-chiral topological order on the 2d bulk.

For Haagerup symmetry  $\mathcal{H}_3$  = Rep( $H_3$ ), we place  $\mathcal{Z}(\mathcal{H}_3)$ on the  $(2 + 1)$ D bulk of SymTFT, which means the bulk is a weak Hopf quantum double model with input data given by *H*3. The bulk topological excitation is characterized by  $\mathcal{Z}(\mathcal{H}_3) \simeq_{\otimes, \text{br}} \text{Rep}(D(H_3))$ , where the equivalence is both monoidal and braided, and  $D(H_3)$  denotes the quantum double of *H*<sup>3</sup> (see [\[43\]](#page-6-21) for details on the weak Hopf quantum double model). The symmetry boundary is chosen as  $B_{sym} = \mathcal{H}_3 =$  $Rep(H<sub>3</sub>)$ , meaning that the symmetry boundary is a smooth boundary for the quantum double model. The boundary input data is  $H_3$  (regarded as a comodule algebra over  $H_3$ ). For the physical boundary, we can choose either a gapped or gapless boundary condition, and the resulting lattice model will possess Haagerup fusion category symmetry.

*Haagerup Fusion Symmetric Cluster Ladder Model.* — To construct the lattice model with Haagerup fusion category symmetry, we first introduce the generalized Pauli operators. The regular action of a Haagerup weak Hopf algebra  $H_3$  on itself can be viewed as a generalization of Pauli *X*-type operators. For the left action  $H \cap H$ , we define:

$$
\overrightarrow{X}_g|h\rangle = |gh\rangle, \quad \overleftarrow{X}_g|h\rangle = |hS^{-1}(g)\rangle, \quad \forall g, h \in H_3. \quad (11)
$$

The dual space  $\hat{H}_3 := \text{Hom}(H_3, \mathbb{C})$  is also a weak Hopf algebra. There are also canonical actions of the dual weak Hopf algebra  $\hat{H}_3$  on the Hopf qudit  $H_3$ , defined using Sweedler's notation as follows:

$$
\varphi \longrightarrow x := \sum_{(x)} x^{(1)} \langle \varphi, x^{(2)} \rangle, \quad x \longrightarrow \varphi := \sum_{(x)} \langle \varphi, x^{(1)} \rangle x^{(2)}, \tag{12}
$$

for all  $\varphi \in \hat{H}_3$  and  $x \in H_3$ . For the left action  $\hat{H}_3 \cap H_3$ , we define:

$$
\vec{Z}_{\Psi}|h\rangle = |\Psi - h\rangle = \sum_{(h)} \Psi(h^{(2)})|h^{(1)}\rangle, \tag{13}
$$

$$
\overleftarrow{Z}_{\psi}|h\rangle = |h - \hat{S}(\psi)\rangle = \sum_{(h)} \psi(S(h^{(1)}))|h^{(2)}\rangle.
$$
 (14)

These operators can be regarded as generalized Pauli *Z*-type operators.

Our construction of local operators is based on the comodule algebra over  $H_3$ . By definition, an algebra  $K$  is referred to as a left  $H_3$ -comodule algebra  $[68]$  if there exists a map  $\beta: K \to H_3 \otimes K$  that satisfies the following properties:

$$
\beta(xy) = \beta(x)\beta(y),\tag{15}
$$

and

$$
(1_{H_3} \otimes x)\beta(1_K) = (\varepsilon_R \otimes id_K) \circ \beta(x), \tag{16}
$$

for all  $x, y \in K$ . Using Sweedler's notation, the coaction  $\beta(x)$ is expressed as  $\sum_{[x]} x^{[-1]} \otimes x^{[0]}$ , with higher coactions represented as  $\beta_2(x) = \sum_{[x]} x^{[-2]} \otimes x^{[-1]} \otimes x^{[0]}$ , and so forth. Each topological boundary condition corresponds to an indecomposable comodule algebra *K* over *H*3. This comodule algebra also corresponds to an indecomposable module category M*<sup>K</sup>* over  $\mathcal{H}_3$ , as well as a Lagrangian algebra  $\mathcal{A}_K$  in the bulk quantum double phase  $\mathcal{Z}(\mathcal{H}_3)$ .

The model is put on an ultra-thin sandwich lattice (regarded as a weak Hopf quantum double model [\[43\]](#page-6-21)):

Periodic or open boundary conditions can be applied in the horizontal direction. The bulk edges are drawn in black, with the edge Hilbert space chosen as the Haagerup weak Hopf qudit  $H_3$ . The edges of the symmetry boundary are drawn in blue, with the edge space given by the left comodule algebra  $K = H_3$ . The edges of the physical boundary are drawn in red, where the edge space can be chosen as an arbitrary right *H*<sub>3</sub>comodule algebra *J*. This means that the total Hilbert space has well-defined tensor-product structure.

Observe that, in the described lattice structure, the bulk resides to the left of the symmetry boundary and to the right of the physical boundary when moving along the positive boundary direction. Therefore, the associated comodule algebras *K* and  $J$  should be selected as a left  $H_3$ -comodule algebra and a right *H*3-comodule algebra, respectively. Modifying the configuration of edge orientations in the lattice leads to different models, but does not alter the underlying physics of the system.

The smooth boundary corresponds to  $K = H_3$ . In this case, the boundary vertex operator is given by:

<span id="page-4-1"></span>
$$
\underbrace{\textcircled{1}}_{x} \underbrace{h_{\textcircled{2}}}_{y} \quad \xrightarrow{\mathbb{A}_{\nu_{s}}^{K} = \overrightarrow{X}_{\lambda^{(1)}} \otimes \overleftarrow{X}_{\lambda_{k}^{(2)}} \otimes \overleftarrow{X}_{\lambda^{(3)}}},
$$
\n
$$
\xrightarrow{\mathbb{A}_{\nu_{s}}^{K} | x, y, h} = |\lambda^{(1)} x, y S^{-1}(\lambda^{(2)}), h S^{-1}(\lambda^{(3)})\rangle.
$$
\n(18)

where  $\lambda$  is the Haar integral of  $H_3$  (Eq. [\(10\)](#page-2-1)). The cocommutativity of  $\lambda$  ensures that the operator  $\mathbb{A}_{\nu_s}^K$  is independent of the specific starting link  $s = (v_s, f)$  chosen at the vertex  $v_s$ . Consequently,  $A_{v_s}^K$  depends only on the vertex  $v_s$  itself. The symmetry boundary Hamiltonian is defined as

$$
\mathbb{H}_{sym} = -\sum_{v_s} \mathbb{A}_{v_s}^K, \tag{19}
$$

where the sum runs over all vertices in the symmetry boundary.

The face operator is constructed from generalized Pauli *Z* operators as follows:

$$
g \underbrace{\overbrace{\left(\bigcup_{i=1}^{K}\mathcal{F}_{i}\right)}^{X}}_{y} h \qquad \mathbb{B}_{f}^{\psi} = \overrightarrow{Z}_{\psi^{(1)}} \otimes \overleftarrow{Z}_{\psi^{(2)}} \otimes \overleftarrow{Z}_{\psi^{(3)}} \otimes \overrightarrow{Z}_{\psi^{(4)}}^{J}.
$$

Written explicitly, we have

$$
\mathbb{B}_f^{\Psi}|g,y,h,x\rangle = \sum \Psi\left(g^{(2)}S(\mathbf{y}^{[-1]})S(h^{(1)})x^{[1]}\right)|g^{(1)},\mathbf{y}^{[0]},h^{(2)},x^{[0]}\rangle.
$$

By setting  $\psi$  to be the Haar measure  $\Lambda \in \hat{H}_3$ , we obtain the face stabilizer operator  $\mathbb{B}_f = \mathbb{B}_f^{\Lambda}$ , and the corresponding bulk Hamiltonian is

$$
\mathbb{H}_{\text{bk}} = -\sum_{f} \mathbb{B}_{f}^{H},\tag{21}
$$

(20)

where the sum runs over all faces of the lattice.

The physical boundary can be chosen to be either gapped or gapless. In the gapped case, we assign a right  $H_3$ -comodule algebra to each edge of the physical boundary. The vertex operator can be constructed in a similar way as in Eq. [\(18\)](#page-4-1) (see Ref. [\[56\]](#page-7-4), where we need to use the symmetric separability idempotent of *J*). The physical boundary Hamiltonian is given by

$$
\mathbb{H}_{\text{phys}} = -\sum_{v_p} \mathbb{A}^J_{v_p},\tag{22}
$$

where the sum runs over all vertices  $v_p$  of the physical boundary.

The cluster ladder model that has Haagerup fusion category symmetry is thus given by

<span id="page-4-0"></span>**H**

$$
\mathbf{H}_{H_3}^{K,J} = \mathbb{H}_{\text{bk}} + \mathbb{H}_{\text{sym}} + \mathbb{H}_{\text{phys}}.\tag{23}
$$

It can be proven that all local operators commute with each other. Fixing symmetry boundary as smooth boundary, viz.,  $K = H_3$ , different choices of comodule algebra *J* over the Haagerup weak Hopf algebra  $H_3$  give rise to different  $H_3$ symmetric phases.

In fact, the model has a larger symmetry. Since  $H_3 \simeq$ Rep( $H_3$ ), the Grothendieck group Gr( $H_3$ ) of the category is generated by the irreducible characters  $\chi_{\Gamma}$  of  $H_3$ , and

$$
\chi_{\Gamma} \cdot \chi_{\Phi} = \chi_{\Gamma \otimes \Phi} = \sum_{\Psi} N_{\Gamma,\Phi}^{\Psi} \chi_{\Psi},\tag{24}
$$

where  $N_{\Gamma,\Phi}^{\Psi} \in \mathbb{Z}_{\geq 0}$  are the fusion multiplicities. The character algebra is given by  $R(\mathcal{H}_3) = \text{Gr}(\mathcal{H}_3) \otimes_{\mathbb{Z}} \mathbb{C}$ , which is a subalgebra of the dual weak Hopf algebra  $\hat{H}_3$ . This means that the Haagerup fusion category symmetry is a sub-symmetry of the dual Haagerup weak Hopf symmetry *H*ˆ 3.

A crucial special case is the cluster state model, where *J* is chosen as the trivial comodule algebra. In this case, all physical boundary operators become trivial and can be removed from the Hamiltonian. This makes the model equivalent to a weak Hopf quantum double model that has one smooth boundary and one rough boundary.

To find the symmetry of the Haagerup cluster state model, we deform the ladder (with periodic boundary conditions) into a cone. We introduce a vertex  $v_{\text{rough}}$  on the rough boundary (the apex of the cone) and a face  $f_{\text{smooth}}$  on the smooth boundary (the base of the cone):

In this way, we can regard the model as a quantum double model on a sphere. The symmetry operator at the smooth boundary is the face operator  $W_{\psi} = \mathbb{B}_{f_{\text{smooth}}}^{\psi}$ . We have the relation  $W_{\psi}W_{\phi} = W_{\psi \cdot \phi}$  with  $\psi, \phi \in \hat{H}_3$ . When  $\psi \in \text{Cocom}(\hat{H}_3)$ , the operator  $\mathbb{B}_{f_{\text{smooth}}}^{\psi}$  will commute with the Hamiltonian [\[43,](#page-6-21) [69\]](#page-7-17). This implies that the model has a  $Cocom(\hat{H}_3)$  symmetry. For  $H_3 = \text{Rep}(H_3)$ , its character algebra is contained in  $Cocom(\hat{H}_3)$ , and thus the model also has Haagerup fusion category symmetry. The rough boundary also gives symmetry operators  $W_h = \mathbb{A}_{v_{\text{rough}}}^h$ , with the relation  $W_h W_g = W_{hg}$ . When  $h \in \text{Cocom}(H_3)$ ,  $W_h$  commutes with the Hamiltonian. This implies that the model has a  $Cocom(H_3)$  symmetry. For open manifolds, there is no need for the symmetry elements to be cocommutative, and thus the symmetry becomes  $\hat{H}_3 \times H_3$ . The result is summarized in Theorem [1.](#page-1-3)

For the general cluster ladder model, due to the fact that *J* is not trivial, the symmetry  $H_3$  from the rough boundary is not broken. Using a similar discussion as above, we find that the dual symmetry  $\hat{H}_3$  still exists. Thus, for periodic boundary conditions, the model has  $Cocom(\hat{H}_3)$  symmetry, while for open boundary conditions, the model has  $\hat{H}_3$  symmetry. In both cases, the symmetry contains  $\mathcal{H}_3$  as a sub-symmetry.

*Matrix-Product State Representation of Ground State.* — The cluster state model can be solved using the weak Hopf matrix product state developed in Refs. [\[42,](#page-6-23) [43,](#page-6-21) [55,](#page-7-3) [56\]](#page-7-4). Here, we will only provide the ground state for the cluster state model. For a more general cluster ladder model, the solution can be obtained based on the discussion in Ref. [\[56\]](#page-7-4).

For edges on the smooth boundary, the local tensor is chosen as the comultiplication of the Haar integral  $\lambda \in H_3$ :

$$
\Delta(\lambda) = \frac{\lambda^{(2)}}{\lambda^{(1)}}.
$$
 (25)

The local tensor for a bulk edge corresponds to  $\Delta_2(\lambda)$ :

$$
\Delta(\lambda) = \frac{\lambda^{(3)} - \lambda^{(2)}}{\lambda^{(1)}}.
$$
 (26)

The local tensor for a face corresponds to the Haar measure  $\Lambda \in \hat{H}_3$ , which is introduced to glue the edge tensors together:

 $(id \otimes id \otimes \hat{S}) \circ \hat{\Delta}(\Lambda) =$  $\hat{S}(\Lambda^{(3)}) \longrightarrow \Lambda \longrightarrow \Lambda^{(2)}$ Λ (1)  $(27)$ 

The Haagerup cluster state is defined as the following ten-

sor network state:

The red free leg represents the physical degrees of freedom. This tensor network forms the ground state of the Haagerup cluster state model.

*Conclusion and Discussion.*— In this work, we propose a cluster state model that possesses Haagerup fusion category symmetry. The ground state and symmetry properties of the model are discussed in detail. Despite the progress made, there are still several directions to explore further: (i) The conformal field theory (CFT) perspective of the model needs to be studied. We have not addressed the central charge, entanglement properties, and other related aspects; however, we believe these can be investigated in a manner similar to that in Refs. [\[30](#page-6-18)[–33\]](#page-6-19), likely through numerical approaches. (ii) The gapless model is also an interesting direction to explore. We mainly discussed the gapped lattice model, but if we introduce a gapless physical boundary, the model becomes gapless. For anyonic chain-based models, this has been discussed in Ref. [\[32\]](#page-6-24), and similar results should apply to our model. (iii) The application of the model in measurement-based quantum computation is another interesting avenue. For the finite group case, this has been partially discussed in Ref. [\[54\]](#page-7-2), but for general non-Abelian groups, Hopf algebras, and weak Hopf algebras, the problem remains largely open. All these problems will be left for future work.
