Different variants of partial orders among quantum states arise naturally in the context of various quantum resources. For example, in discrete variable quantum computation, stabilizer operations naturally produce an order between input and output states; in technical terms this order is vector majorization of discrete Wigner functions in discrete phase space. The order results in inequalities for magic monotones. In the continuous variable case, a natural counterpart would be continuous majorization of Wigner functions in quantum phase space. Indeed, this concept was recently proposed and explored (mostly restricting to the single-mode case) in Van Herstraeten, Jabbour, Cerf, Quantum 7, 1021 (2023). In this work, we develop the theory of continuous majorization in the general N-mode case. In particular, we propose extensions to include states with finite Wigner negativity. Among our results, we prove a conjecture made by Van Herstraeten, Jabbour and Cerf for the convex hull of N-mode Gaussian states, and a phase space counterpart of Uhlmann's theorem of majorization.

# I. INTRODUCTION

Continuous variable (CV) systems are described by operators with eigenvalues forming a continuous set. Most of the examples in this class are built out of harmonic oscillators, appearing in many different guises in different areas of physics. CV methods are therefore central in many applications of quantum information science; well-known reviews on this subject include *e.g.*, [1-4] In particular we want to mention continuous variable approaches to quantum computing [5, 6].

In quantum computing, an important resource is magic, aka non-stabilizerness, which is needed for advantage over classical computing. For qubits, this result follows from the Gottesman-Knill theorem [7], which was later extended for qudits and continuous variable systems [8–10]. Both in the discrete variable (DV) case of qudits and in the CV case, quantum advantage requires computation involving states whose Wigner function takes negative values in some parts of the quantum phase space. Thus the resource magic can also be called Wigner negativity, and indeed this is the convention for continuous variables.

Important quantum information theoretic resources and their loss under information processing under "free operations" are described in the framework of resource theories [11]. An example is the resource theory of entanglement for bipartite quantum systems where the free operations are local operations combined with classical communication (LOCC), and the loss of entanglement is tracked quantitatively by the entanglement entropy, the relevant "resource monotone" in this context. Furthermore, by Nielsen's theorem [12] LOCC produces and requires a preorder among quantum states, called majorization. Conversely, a majorization relation between a pair of states implies an inequality for their entanglement entropies.

In DV quantum computing, relevant resource theories are resource theories of magic, introduced in [13]. One natural choice of free operations is the class of stabilizer protocols, which includes e.g. acting with Clifford unitaries; the free states are stabilizer states, while the resource states are magic aka non-stabilizer states.

In DV resource theories of magic, several magic monotones have been introduced [13–19]: for this work we single out the mana [13]. Recently, a preorder based on vector majorization adapted to discrete Wigner functions in the discrete quantum phase space was investigated by Koukoulekidis and Jennings in [20]. They showed that, when applying a free operation, the input state always majorizes the output state. Under these operations, the mana is always non-increasing, signaling a loss of magic.

Compared to the DV case, the CV case is murkier. A natural choice of free operations would be those that always map Wigner-positive states to Wigner-positive states,  $\mathcal{W}_+ \to \mathcal{W}_+$ , but they are difficult to classify. A more convenient choice is Gaussian protocols, which map within a subset of  $\mathcal{W}_+$ , the convex hull of Gaussian states. This class includes *e.g.* Gaussian operations and homodyne measurements combined with conditioning based on measurement outcomes. Gaussian protocols are also a very important and easily implementable class of protocols for many other applications beyond quantum computing. For resource states there are then two possible natural choices: Wigner-negative states, leading to the resource theory of Wigner negativity [21], or non-Gaussian states, leading to the resource theory of non-Gaussianity [22]. In both settings an interesting monotone is the Wigner logarithmic negativity [23], the CV counterpart of mana, and it was shown to be monotonically non-increasing under the free operations, Gaussian protocols [21, 22]. However, what seems to be missing in order to have a complete resource theory, is the concept of a preorder.

In this work we address the question what should be an appropriate preorder for either resource theory.

A natural guess for the preorder is to find a CV generalization of the vector majorization of discrete Wigner functions of the DV case. In the CV case, Wigner functions are real-valued functions on  $\mathbb{R}^{2N}$ . In mathematics, the theory of continuous majorization, applicable to functions, has been developed over the years [24–27]. In [28], Van Herstraeten, Jabbour and Cerf imported the concept to quantum phase space, proposing it as a natural way to compare "randomness" of Wigner functions for Wigner-positive states, proving various properties and conjecturing that coherent states in this way majorize all other Wigner-positive states. Since continuous majorization of Wigner functions is the natural counterpart of vector majorization of discrete Wigner functions, it then appears as a natural candidate for a preorder for the resource theories of non-Gaussianity or Wigner negativity. This would already establish continuous majorization in quantum phase space as a fundamental concept.

In this work we develop the theory of continuous majorization of Wigner functions in quantum phase space, which we shorten to Wigner majorization, proving significant extensions and results first in the N-mode case of Wigner-positive states, in particular proving the conjecture of [28] for the convex hull of N-mode Gaussian states. Motivated by resource theories, we investigate continuous majorization between Wigner functions of input and output states under Gaussian protocols, limiting the focus here on Gaussian channels. We then propose three possible ways to extend the definition to states with finite non-vanishing Wigner negativity In this most general case we are able to prove some interesting results such as a quantum phase space counterpart of Uhlmann's theorem of majorization. For the preorder question, we will find mixed results, reflecting the rich structure in the classification of CV states compared to the DV case.

This work is structured as follows. This introduction is followed by Sec. II summarizing the main results. Secs. III, IV, V give a more technical presentation, followed by conclusions in Sec. VI and Appendices with technical details.

# **II. SUMMARY OF THE MAIN RESULTS**

In this section we provide an overview of the main results reported in this manuscript, postponing their proofs and explicit computations to the forthcoming sections and the appendices. Before the summary, we review continuous majorization between positive functions and its application to defining the *Wigner majorization*, a preorder relation in the space of quantum CV states.

#### A. Review on Wigner majorization

For later reference we begin with a brief review of vector majorization. Consider a pair of vectors  $\mathbf{p}, \mathbf{q} \in \mathbb{R}^n$ . We reorder the components (note that they can also be negative) into descending order and relabel them to define  $\mathbf{p}^{\downarrow} = (p_1^{\downarrow}, p_2^{\downarrow}, \dots, p_n^{\downarrow}), \ \mathbf{q}^{\downarrow} = (q_1^{\downarrow}, q_2^{\downarrow}, \dots, q_n^{\downarrow})$  such that  $p_1^{\downarrow} \ge p_2^{\downarrow} \ge \cdots \ge p_n^{\downarrow}$  and  $q_1^{\downarrow} \ge q_2^{\downarrow} \ge \cdots \ge q_n^{\downarrow}$ . We then compare partial sums of the components. If the inequalities

$$\sum_{i=1}^{k} p_i^{\downarrow} \ge \sum_{i=1}^{k} q_i^{\downarrow} \tag{1}$$

hold for all k = 1, ..., n, then we say that the vector pweakly majorizes the vector q and denote  $p \gg q$ . If in addition for k = n we have the equality

$$\sum_{i=1}^{n} p_i^{\downarrow} = \sum_{i=1}^{n} q_i^{\downarrow} , \qquad (2)$$

we say that the vector p majorizes the vector q and we denote  $p \succ q$ .

These definitions can be extended to the discretely infinite case; for majorization the sums  $\sum_{i=1}^{\infty}$  replacing the finite sums in (2) must be finite. A special application is the case when p, q are probability vectors associated with a discrete random variable (so that the components are non-negative). In this case (2) holds due to the unit normalization of probability vectors, and if  $p \succ q$ , we can think of the distribution p being "more ordered" or "less random" than the distribution q. This notion can then be implemented to define quantum state majorization in terms of the eigenvalues of density operators. Given two DV or CV states with density operators  $\hat{\rho}_1$  and  $\hat{\rho}_2$ , let us call  $\lambda_j$  and  $\kappa_j$ , with  $j = 1, \ldots, n$  or  $j = 1, 2, \ldots, \infty$  their respective eigenvalues. We then assemble the eigenvalues into ordered (probability) vectors  $\lambda^{\downarrow}, \kappa^{\downarrow}$  and say that the state  $\hat{\rho}_1$  majorizes the state  $\hat{\rho}_2$ , and denote  $\hat{\rho}_1 \succ_{\text{DM}} \hat{\rho}_2$ , if and only if  $\lambda \succ \kappa$ . We will henceforth refer to this majorization relation as *density matrix majorization* in distinction to the Wigner majorization which will be our main topic. We will also compare density matrix majorization with Wigner majorization to understand whether the two concepts may coincide in some instances.

Continuous majorization [29, 30] is a generalization for functions, introduced in [24] and induces a preorder in the space of positive integrable functions on  $\mathbb{R}^{2N}$ . To avoid clutter, throughout the manuscript, we denote the integrals of these functions on the entire  $\mathbb{R}^{2N}$  as

$$\int_{\mathbb{R}^{2N}} f(\boldsymbol{r}) d\boldsymbol{r} \equiv \int f(\boldsymbol{r}) d\boldsymbol{r} \,, \tag{3}$$

namely without specifying any integration domain.

To define the continuous majorization precisely, consider two positive functions  $f, g: \mathbb{R}^{2N} \to [0, \infty)$  (we will

later address the question what happens if the functions are allowed to have negative values). We first define the generalization of weak majorization of vectors, following [25, 30] (also called a "spectral order relation"). We say that f weakly majorizes g and denote  $f \gg g$  if one of the following equivalent statements is true [25, 30]:

1.

$$\int [f(\boldsymbol{r}) - t]_+ d\boldsymbol{r} \ge \int [g(\boldsymbol{r}) - t]_+ d\boldsymbol{r} \,, \tag{4}$$

for any  $t \ge 0$ , where

$$[y]_{+} = \max(y, 0).$$
 (5)

$$\mathbf{2}$$

$$\int \Phi(f(\boldsymbol{r})) d\boldsymbol{r} \ge \int \Phi(g(\boldsymbol{r})) d\boldsymbol{r} \,, \tag{6}$$

for all non-negative increasing convex functions  $\Phi$ :  $[0,\infty] \to [0,\infty]$  such that  $\Phi(0) = 0$ .

3.

$$\int_{t}^{\infty} m_f(s) ds \ge \int_{t}^{\infty} m_g(s) ds \,, \tag{7}$$

for any  $t \ge 0$ , where the *level function*  $m_f$  is defined as

$$m_f(t) \equiv \operatorname{Vol}(\{\boldsymbol{r} \in \mathbb{R}^{2N} \mid f(\boldsymbol{r}) \ge t\}).$$
(8)

4.

$$\int_{0}^{v} f^{\downarrow}(u) du \ge \int_{0}^{v} g^{\downarrow}(u) du , \qquad (9)$$

for any  $v \in [0, \infty)$ , where  $f^{\downarrow}, g^{\downarrow} : [0, \infty] \to [0, \infty]$ are the *decreasing rearrangements* of f and g respectively, defined as

$$f^{\downarrow}(u) = \inf \left\{ s \in [0, \infty) \mid m_f(s) \le u \right\} = m_f^{-1}(u) \,.$$
 (10)

Note in particular that the decreasing rearrangement of a function (10) is the counterpart of the decreasing rearrangement  $p^{\downarrow}$  of a vector p, but while the function fcan be multivariate, its decreasing rearrangement  $f^{\downarrow}$  always has a single variable. Note also that the integral inequalities (9) are the counterpart of the partial sum inequalities (1). It is worth emphasizing that the weak majorization  $\gg$  satisfies the remarkable property

$$f \gg g, f \gg h \quad \Rightarrow \quad f \gg tg + (1-t)h, \ t \in [0,1], \ (11)$$

which can be proved by exploiting the concavity of the functional in (5).

If, in addition to one of the conditions (4)-(9), we have that

$$\int f(\boldsymbol{r})d\boldsymbol{r} = \int g(\boldsymbol{r})d\boldsymbol{r} \,, \tag{12}$$

then we say that f majorizes g and we denote it as  $f \succ g$ . The equation (12) is the counterpart of the equation (2).

Note that two functions f and g can have the same level function:  $m_f = m_g$  (and thus also the same decreasing arrangement  $f^{\downarrow} = g^{\downarrow}$ ). In this case we say that f and g are *level-equivalent*,  $f \sim g$ , and define an equivalence class  $[f]_{\sim} = [g]_{\sim}$ . Thus the continuous majorization in fact applies to equivalence classes:  $[f]_{\sim} \succ [g]_{\sim} \Leftrightarrow f \succ g$ . Note also that continuous majorization can be defined for positive functions on more general measure spaces. However, for this work, we restrict our analysis to Euclidean spaces of even dimensionality.

For later convenience, we recall that, given  $f, g : \mathbb{R}^{2N} \to [0, \infty)$ , a sufficient condition for the relation  $f \succ g$  is the existence of an integral kernel  $k : \mathbb{R}^{2N} \times \mathbb{R}^{2N} \to \mathbb{R}$  such that [26]  $k(\mathbf{r}, \mathbf{z}) \geq 0 \quad \forall \mathbf{r}, \mathbf{z} \in \mathbb{R}^{2N}$ ,

$$g(\mathbf{r}) = \int k(\mathbf{r}, \mathbf{z}) f(\mathbf{z}) d\mathbf{z} , \qquad (13)$$

and

$$\int d\boldsymbol{r} k(\boldsymbol{r}, \boldsymbol{z}) = 1, \qquad \int d\boldsymbol{z} k(\boldsymbol{r}, \boldsymbol{z}) = 1.$$
(14)

This condition also has a counterpart in the context of discrete probability distributions, where the kernel k is replaced by a bistochastic matrix. Leveraging this analogy, we will sometimes refer to a positive kernel satisfying (14) as *bistochastic kernel*.

The theory of continuous majorization has been recently applied to studying bosonic quantum states by introducing the Wigner majorization (continuous majorization of Wigner functions in quantum phase space) [28]; an extension to a fermionic case has been introduced in [31]. In this work we focus on further developing the theory of Wigner majorization for bosonic systems [58]. Consider a system described in terms of a finite set of degrees of freedom represented by pairs of Hermitian canonical operators  $\hat{q}_j$  and  $\hat{p}_j$ , with  $j = 1, \ldots, N$ , such that

$$[\hat{q}_i, \hat{p}_j] = i\delta_{i,j}, \quad [\hat{q}_i, \hat{q}_j] = [\hat{p}_i, \hat{p}_j] = 0.$$
 (15)

We refer to these operators as canonical quadrature operators and, for convenience, we collect them into a vector  $\hat{\boldsymbol{r}} \equiv (\hat{q}_1, \ldots, \hat{q}_N, \hat{p}_1, \ldots, \hat{p}_N)^{\text{t}}$ . Since the operators  $\hat{q}_i$ and  $\hat{p}_i$  have continuous eigenvalues on the real line, this framework is known as quantum CV and we call CV systems those systems allowing for this description [1].

The states of CV systems are described by density matrices, which are operators on an infinite dimensional Hilbert space. Given a CV state with density matrix  $\hat{\rho}$ , we define the characteristic function  $\chi_{\hat{\rho}}$  as

$$\chi_{\hat{\rho}}(\boldsymbol{r}) \equiv \operatorname{Tr}\left(\hat{\rho}e^{i\boldsymbol{\hat{r}}^{\mathrm{t}}J\boldsymbol{r}}\right) \,, \tag{16}$$

where J is the standard symplectic matrix

$$J \equiv \begin{pmatrix} \mathbf{0} & \mathbf{1} \\ -\mathbf{1} & \mathbf{0} \end{pmatrix}, \tag{17}$$

with **0** representing the  $N \times N$  matrix with all the entries equal to zero and **1** is the  $N \times N$  identity matrix. The vector  $\mathbf{r} \in \mathbb{R}^{2N}$  can be written as  $\mathbf{r} = (\mathbf{q}, \mathbf{p})^{t} \equiv (q_1, \ldots, q_N, p_1, \ldots, p_N)^{t}$ , where these 2N coordinates parametrize the quantum phase space. To avoid confusion between the quadrature operators and the corresponding phase-space variables, we denote the former with the hat and the latter without it.

The *Wigner function* is the (symplectic) Fourier transform of the characteristic function, namely [1]

$$W_{\hat{\rho}}(\boldsymbol{r}) = \frac{1}{(4\pi^2)^N} \int d\boldsymbol{r'} e^{-\mathrm{i}\boldsymbol{r'} J\boldsymbol{r'}} \chi_{\hat{\rho}}(\boldsymbol{r'}) \,. \tag{18}$$

Due to the normalization of the density matrix  $\text{Tr}\hat{\rho} = 1$ , the integral of the Wigner function (18) on the entire phase space is one, namely

$$\int W_{\hat{\rho}}(\boldsymbol{r})d\boldsymbol{r} = 1.$$
(19)

Since  $W_{\hat{\rho}}(\mathbf{r})$  is not necessarily a positive function, the condition (19) implies that the Wigner function is a *quasi-probability distribution*, which reduces to an ordinary probability distribution when it is positive [59]. We call the CV states for which this happens *Wigner-positive states*. We find it worth stressing that Wigner functions are functions defined on the quantum phase space  $\mathbb{R}^{2N}$  and uniquely identify a quantum state.

Here, the theory of continuous majorization enters and allows to define a new notion of majorization between quantum states, that we call in this work "Wigner majorization". The idea of Wigner majorization between states with positive Wigner functions was introduced in [28], where the authors exploited this tool to study information-theoretic properties of Wigner functions. Given two states  $\hat{\rho}_1$  and  $\hat{\rho}_2$  with positive Wigner functions  $W_1$  and  $W_2$  respectively, following [28] we say that the state  $\hat{\rho}_1$  Wigner-majorizes  $\hat{\rho}_2$ , in symbols  $\hat{\rho}_1 \succ_w$  $\hat{\rho}_2$ , if and only if  $W_1 \succ W_2$ . Notice that conditions 1-4 are valid for positive integrable functions, and, therefore, the definition of Wigner majorization given above can only be applied between states with positive Wigner functions. As we will discuss later, one of the main results of this manuscript is the extension of the definition of Wigner majorization to more general Wigner functions and states.

As we will elaborate more in the forthcoming sections, a widely employed class of quantum operations is the one of *Gaussian unitaries*, namely unitary transformations generated by quadratic combinations of the quadrature operators. More precisely, these operations are implemented by a unitary operator of the following form

$$\hat{U} = \exp\left(-i\bar{\boldsymbol{r}}^{t}J\,\hat{\boldsymbol{r}}\right)\exp\left(i\hat{\boldsymbol{r}}^{t}h\,\hat{\boldsymbol{r}}\right)\exp\left(i\bar{\boldsymbol{r}}^{t}J\,\hat{\boldsymbol{r}}\right)\,,\qquad(20)$$

with h being a  $2N \times 2N$  Hermitian matrix and  $\bar{r}$  a vector with 2N entries [1]. We find it worth remarking that applying a Gaussian unitary transformation on a CV state amounts to performing a translation by a vector  $\bar{r}$  and a symplectic transformation in the coordinates parameterizing the corresponding Wigner function. The translation and the symplectic transformation are changes of coordinates of the quantum phase space, with a unit determinant. From this fact, through the conditions 1-4, one can show that two Wigner functions that differ by a symplectic transformation are level-equivalent. Thus, the corresponding pair of states related by a Gaussian unitary are equivalent in the sense of Wigner majorization [28]. In the rest of the manuscript, we will refer to two CV states  $\hat{\rho}_1$  and  $\hat{\rho}_2$  such that  $\hat{\rho}_1 \succ_{W} \hat{\rho}_2$  and  $\hat{\rho}_2 \succ_{W} \hat{\rho}_1$ as majorization-equivalent.

#### B. Majorization for positive Wigner functions

We now begin our summary of the results of this work on Wigner majorization between quantum CV states. We start with results for states with positive Wigner functions. These outcomes are therefore obtained by exploiting the definition of Wigner majorization through the conditions 1-4.

An important class of CV states with positive Wigner functions is the one of *Gaussian states*, which are described by Gaussian Wigner functions. Given a Gaussian state with density matrix  $\hat{\rho}$ , its Wigner function has the general form [2, 3]

$$W_{\hat{\rho}}(\boldsymbol{r}) = \frac{e^{-\frac{1}{2}(\boldsymbol{r}-\bar{\boldsymbol{r}})^{\mathrm{t}}\gamma^{-1}(\boldsymbol{r}-\bar{\boldsymbol{r}})}}{(2\pi)^{N}\sqrt{\det\gamma}}, \qquad (21)$$

where

$$\bar{r}_j \equiv \operatorname{Tr}\left[\hat{\rho}\,\hat{r}_j\right]\,,\quad \gamma_{ij} \equiv \frac{1}{2}\operatorname{Tr}\left[\hat{\rho}\left\{(\hat{r}_i - \bar{r}_i), (\hat{r}_j - \bar{r}_j)\right\}\right]\,,\tag{22}$$

and  $\{,\}$  denotes the anticommutator. The values  $\bar{r}_j$  are the first moments of the quadrature operators, while  $\gamma = (\gamma_{ij})$  is a  $2N \times 2N$  real, symmetric, and positive definite matrix, called the *covariance matrix*. Gaussian states are widely employed in various contexts, including quantum information and quantum optics, and their study is also relevant for experiments.

To study majorization, the Wigner function (21) of a Gaussian state can be simplified. It is not difficult to prove that a displacement of the phase space coordinates (a Gaussian unitary operation) does not alter the integrals in (4), (6), (7) and (9). Thus, given the Wigner function (21), we can always choose  $\bar{\boldsymbol{r}} = 0$  without altering the majorization properties of Gaussian Wigner functions and the corresponding Gaussian states. For this reason, when not otherwise specified, from now on we consider Gaussian states with vanishing first moments. Moreover, notice that not all the real, symmetric, positive definite matrices can be covariance matrices of a quantum Gaussian state; the uncertainty principle imposes a constraint on the eigenvalues of  $\gamma$ , which is encoded in the inequality [2]

$$\gamma + \frac{\mathrm{i}}{2}J \ge 0\,,\tag{23}$$

where J is defined in (17). The covariance matrix has 2N(2N-1) independent parameters, but not all of these affect the majorization between two Gaussian Wigner functions. To show this fact, we remark that any real even-dimensional positive definite matrix, and therefore also the covariance matrix, can be decomposed according to the Williamson decomposition [32], namely

$$\gamma = S^{t} \mathcal{D}S, \quad \mathcal{D} = \operatorname{diag}(\sigma_{1}, \dots, \sigma_{N}) \oplus \operatorname{diag}(\sigma_{1}, \dots, \sigma_{N}),$$
(24)

where S is a symplectic matrix (sometimes we will refer to it as symplectic basis) and  $\sigma_i$  are called symplectic eigenvalues. Given the constraint (23),  $\sigma_i \geq 1/2$ . If  $\gamma$  is the covariance matrix of a pure state,  $\sigma_i = 1/2$ ,  $\forall i$  [2]. The decomposition (24) provides a natural basis for the phase space coordinates. Changing the coordinates by  $\mathbf{r} \to S^{-t}\mathbf{r}$ , we can write the Wigner function (21) with  $\bar{\mathbf{r}} = 0$  as

$$W_{\hat{\rho}}(\boldsymbol{r}) = \prod_{j=1}^{N} \frac{e^{-\frac{r_j^2}{2\sigma_j}}}{2\pi\sigma_j}, \qquad (25)$$

where  $r_j^2 \equiv q_j^2 + p_j^2$ . Since (21) with  $\bar{\boldsymbol{r}} = 0$  and (25) differ only by a symplectic transformation in the phase space coordinates, they are level-equivalent. Thus, only the *N* symplectic eigenvalues affect the Wigner majorization properties of Gaussian states.

To completely characterize the Wigner majorization between Gaussian states, we resort to a result due to Joe [27] that provides a majorization criterion between Gaussian probability distributions. When applied to Gaussian Wigner functions, Joe's result leads to the first result of this manuscript (a simple proof of Joe's result is sketched in [60]).

**Result 1**: Given two Gaussian states  $\hat{\rho}_1$  and  $\hat{\rho}_2$  with Wigner functions  $W_1$  and  $W_2$  and covariance matrices  $\gamma_1$  and  $\gamma_2$  respectively, we have

$$W_1 \succ W_2 \quad \Leftrightarrow \quad \det \gamma_1 \le \det \gamma_2 \,, \tag{26}$$

which induces the Wigner majorization relation

$$\hat{\rho}_1 \succ_{\mathrm{W}} \hat{\rho}_2 \quad \Leftrightarrow \quad \det \gamma_1 \le \det \gamma_2 \,.$$
 (27)

This result is very powerful given that it encodes the Wigner majorization properties of a Gaussian state in a single number computable from a  $2N \times 2N$  matrix. Notice that the determinant of a covariance matrix is given by the square product of all the symplectic eigenvalues. Thus, as anticipated, the Wigner majorization between Gaussian states only depends on the symplectic spectra of the two corresponding covariance matrices. Note that Result 1 also implies that a Wigner majorization order always exists between an arbitrary pair of N-mode Gaussian states. In Sec. III B we discuss explicit examples based on Result 1.

One of the main findings of [28] is the conjecture on the majorization of the pure state  $\hat{\rho}_0$ , defined as the state with Wigner function (25) with all the symplectic eigenvalues  $\sigma_j = 1/2$ , for any  $j = 1, \ldots, N$ . The conjecture states that any mixed state with a positive Wigner function is majorized by  $\hat{\rho}_0$ . In [28] this conjecture is demonstrated for some mixtures of the harmonic oscillator eigenstates, in the single-mode (N = 1) case. Due to Result 1, we can extend the proof of this conjecture to the mixed states belonging to the convex hull of N-mode Gaussian states.

**Result 2**: The *N*-mode pure Gaussian state  $\hat{\rho}_0$  Wignermajorizes every state in the convex hull of *N*-mode Gaussian states, namely

$$\hat{\rho}_0 \succ_{\mathrm{W}} \hat{\rho}, \quad \forall \, \hat{\rho} = \sum_i p_i \hat{\sigma}_i \,,$$
 (28)

where  $\hat{\sigma}_i$  are Gaussian states and  $\sum_i p_i = 1, p_i \ge 0$ .

This result is proved by using (11), (27) and the fact that, among the Gaussian states, the covariance matrix of pure states has the smallest determinant allowed. In Sec. III A, we provide an alternative proof of (28).

In Sec. III A we derive also the following statement.

**Result 3**: Consider a one-parameter family of Gaussian density matrices  $\hat{\rho}(\tau)$ , where  $\tau$  can be a coupling constant, the temperature, or other physical parameters. As a consequence,  $\gamma$  and the symplectic eigenvalues  $\sigma_k$  depend on  $\tau$ . The following majorization criterion as a function of the parameter  $\tau$  holds for any pair of states with  $\tau_2 > \tau_1$ :

$$\partial_{\tau}\sigma_k(\tau) > 0 \ \forall k, \ \forall \tau \in [\tau_1, \tau_2] \Rightarrow \hat{\rho}_{\tau_1} \succ_{\mathrm{W}} \hat{\rho}_{\tau_2} .$$
 (29)

This result is a special case of a more general one: if det  $\gamma(\tau)$  is monotonically decreasing in the interval  $[\tau_1, \tau_2]$ , the right-hand side of (29) follows from Result 1. The specific case of Result 3 helps to compare Wigner majorization and density matrix majorization. It would be insightful to understand whether they coincide in some instances; this question is also related to the interconversibility of Gaussian states [33]. In Sec. III C, we show that Wigner majorization is equivalent to the density matrix majorization if we restrict to single-mode Gaussian states.

**Result 4**: Given two single-mode Gaussian states with density matrices  $\hat{\rho}_1$  and  $\hat{\rho}_2$ , then

$$\hat{\rho}_1 \succ_{\text{DM}} \hat{\rho}_2 \quad \Leftrightarrow \quad \hat{\rho}_1 \succ_{\text{W}} \hat{\rho}_2 \,.$$
 (30)

This statement ceases to be true in general when N > 1. We show this fact in Fig. 1, providing explicit examples of inequivalence between the two majorizations when two-mode Gaussian states are considered. We also identify a subset of pairs of multi-mode states where the two majorizations are equivalent, as discussed in Sec. III C 1.

To conclude our analysis on Wigner majorization

among Gaussian states, in Sec. III B, Result 3 is applied to examples from the context of harmonic lattices. In particular, we show that any N-mode Gaussian thermal state at a given temperature always majorizes another thermal state of the same system at higher temperature. This is consistent with the idea that Wigner majorization orders quantum states based on their mixedness [28]. In addition, we also show that the thermal state of a harmonic chain made by N sites Wigner-majorizes any other thermal state of the same system with a smaller frequency parameter and the same temperature.

Wigner functions play a prominent role in the resource theory of non-Gaussianity and the resource theory of Wigner negativity [21, 22]. In the former case, the free states are given by CV Gaussian states, while, in the latter case, they are given by CV states with positive Wigner functions. In both resource theories, the free operations are given by the so-called Gaussian protocols, including Gaussian measurements and Gaussian channels. A Gaussian channel is a completely positive and trace-preserving operation that maps Gaussian states into Gaussian states. When acting on a Gaussian state, its action on the input covariance matrix  $\gamma$  is given by [1, 34]

$$\gamma \to X\gamma X^{t} + Y, \qquad Y + i\frac{J}{2} \ge iX\frac{J}{2}X^{t}, \qquad (31)$$

where X and Y are  $2N \times 2N$  matrices and Y is additionally symmetric and positive definite. Gaussian channels map Gaussian states into Gaussian states according to (31), but can also be applied to non-Gaussian states. In the latter case, their action is more complicated, as discussed later in this manuscript. To understand whether Wigner majorization plays any role in the context of the aforementioned resource theories, we find it insightful to study the majorization relation between a given input state and the output state obtained after applying a Gaussian channel. Considering first a simple example of single-mode Gaussian channels, we can gain the following insight for N-mode Gaussian channels, discussed in Sec. IV A.

**Result 5**: It is not true that a CV input state always Wigner-majorizes the output state obtained by applying a Gaussian channel or that it is always Wigner-majorized by it. The direction of a Wigner majorization relation depends on the choice of the CV input state and a Gaussian channel acting on it.

As a first consequence, this result implies that the Wigner majorization among CV Wigner-positive states does not allow any counterpart of Nielsen's theorem, where the role of LOCC would be replaced by Gaussian protocols. Furthermore, Result 5 implies a first clear difference between the Wigner majorization among CV states and among DV states. The latter case was investigated in detail in [20]. In the DV case in d dimensions, the discrete Wigner functions can be interpreted as  $d^2$ -dimensional

(quasi)-probability vectors. The Choi-Jamiolkovski (C-J) dual [35, 36] of a positive channel (such as Gaussian channels) gives a convolution relation between the input and output Wigner functions with a bistochastic kernel. This implies that the input Wigner function (vector) always majorizes the output Wigner function. Result 5 shows that in contrast this does not generally happen for CV Wigner-positive states states when Gaussian channels are applied, while Result 6 below will explain why: the convolution kernels are not in general bistochastic.

Given the discussion above, it is natural to try to understand whether we can identify a subclass of *Wigner-majorizing Gaussian channels*. A Gaussian channel  $\mathcal{E}$  belongs to this class if, given an input state  $\hat{\rho}_{in}$ , we have that  $\hat{\rho}_{in} \succ_{W} \mathcal{E}(\hat{\rho}_{in})$ . To find this class of channels when  $\hat{\rho}_{in}$  is a CV positive-Wigner state, we reinterpret a result found in [37] in view of exploiting it in the context of Wigner majorization.

**Result 6:** Given the Wigner function  $W_{\rm in}$  of an input state, the Wigner function  $W_{\rm out}$  of the output state  $\hat{\rho}_{\rm out} \equiv \mathcal{E}(\hat{\rho}_{\rm in})$  is given by

$$W_{\rm out}(\boldsymbol{r}) = \int d\boldsymbol{z} k(\boldsymbol{r}, \boldsymbol{z}) W_{\rm in}(\boldsymbol{z}) , \qquad (32)$$

where the integral kernel is defined as

$$k(\boldsymbol{r}, \boldsymbol{z}) \equiv \frac{e^{-\frac{1}{2}\boldsymbol{r}^{\mathrm{t}}Y^{-1}\boldsymbol{r} - \frac{1}{2}\boldsymbol{z}^{\mathrm{t}}X^{\mathrm{t}}Y^{-1}X\boldsymbol{z} + \boldsymbol{z}^{\mathrm{t}}X^{\mathrm{t}}Y^{-1}\boldsymbol{r}}{(2\pi)^{N}\sqrt{\det Y}}, \quad (33)$$

in terms of the matrices X and Y characterizing the channel  $\mathcal{E}$ . By computing two Gaussian integrals in we find that the kernel k in (33) satisfies the properties

$$\int d\mathbf{r}k(\mathbf{r}, \mathbf{z}) = 1, \qquad \int d\mathbf{z}k(\mathbf{r}, \mathbf{z}) = \frac{1}{\det X}. \quad (34)$$

A proof of the formulas (32)-(33) is reported for completeness in Appendix A. Importantly, note that the convolution formula (32) with the unit normalization of the integral over r (34) plays a central role in the proof of the Eisert-Mari theorem [9]. In the DV case, a convolution formula follows from the Choi-Jamiolkowski dual representation of the action of the channel. However, as we discuss in more detail in Sec. IVA, in the CV case the dual representation is ill-defined, since the C-J dual mapping involves the two-mode squeezed state in the infinite squeezing limit. The formulas (32)-(33) do not rely on the C-J dual mapping and, at least for Gaussian channels, give a well-defined convolution for the Eisert-Mari theorem in the CV case. While we believe that similar convolution formulas can be derived for more general positive channels, it appears to be an important problem to find such generalizations, to strengthen the proof of the Eisert-Mari theorem in the CV case. Comparing (34) with (14), we notice that kis not a bistochastic kernel, unlike in the convolution formula in the DV case. However, using the properties of k and the necessary condition (13) for Wigner majorization for states with positive Wigner functions, we prove the following statement.

**Result 7:** The class of Gaussian channels  $\mathcal{E}_{X,Y}$  characterized by the matrices X and Y such that det X = 1 is a class of Wigner-majorizing channels when applied to CV states with positive Wigner functions, namely, for any CV state  $\hat{\rho}$  with positive Wigner function,

$$\hat{\rho} \succ_{\mathrm{W}} \mathcal{E}_{X,Y}(\hat{\rho}) \,. \tag{35}$$

This class of Gaussian channels includes some important examples. First, notice that the Gaussian unitaries correspond to Gaussian channels with  $Y = \mathbf{0}$  and X symplectic, the latter conditions implying det X = 1. This is a consistency check of the fact that Gaussian unitaries are majorizing channels, despite in a trivial way. Indeed, the output state after a Gaussian unitary is majorizationequivalent to the input state and therefore is majorized by it. In addition to this trivial example, the class of majorizing channels with  $\det X = 1$  includes *classical mixing* channels, namely Gaussian channels which implement displacements on the input state randomly distributed according to a given Gaussian probability distribution and are models of Gaussian noise [1]. We elaborate more on this class of Wigner-majorizing channels, in particular on the classical mixing channels, in Sec. IV B.

#### C. Majorization for generic Wigner functions

The results described in the previous subsection apply to CV states with positive Wigner functions. It is desirable to extend the concept of Wigner majorization to a more general class of CV states including Wignernegativity, and understand the interplay of these extensions with Gaussian channels. The findings reported in this section aim at filling this gap.

First, we introduce three proposals to extend Wigner majorization to CV states whose Wigner functions are not necessarily positive. Physically motivated by resource theory arguments, as discussed later in this section, we also require that the Wigner functions of the considered states are absolutely integrable on the entire phase space, i.e. they belong to  $L^1(\mathbb{R}^{2N})$ . As we will elaborate later in this section and Sec. V A, the states whose Wigner function is not in  $L^1(\mathbb{R}^{2N})$ have a divergent Wigner logarithmic negativity and, from the viewpoint of the resource theories of [21, 22], their resourcefulness is not well-defined. The details, including the limitations of the following definitions, their implications, and some examples, are discussed in Sec. V A. **Result 8:** The following three proposals are definitions of Wigner majorization generalizing the one in Sec. II A, which was valid only for CV states with positive Wigner functions. Consider two *generic* CV states with density matrices  $\hat{\rho}_1$  and  $\hat{\rho}_2$  and Wigner functions  $W_1$  and  $W_2$ respectively and assume that  $W_1, W_2 \in L^1(\mathbb{R}^{2N})$ .

- 1.  $\hat{\rho}_1 \succ_{W} \hat{\rho}_2$  if and only if  $|W_1| \gg |W_2|$ , where the relation  $\gg$  is defined by (4)-(10).
- 2.  $\hat{\rho}_1 \succ_w \hat{\rho}_2$  if and only if one of the two (equivalent) conditions is verified

$$\int [W_1 - t]_+ d\mu - \int [W_2 - t]_+ d\mu \ge 0, \quad \forall t \in \mathbb{R}, \quad (36)$$

where  $[\cdot]_+$  is defined in (5), or

$$\int_{t}^{\infty} m_{W_1}(s)ds - \int_{t}^{\infty} m_{W_2}(s)ds \ge 0, \quad \forall t \in \mathbb{R}, \qquad (37)$$

with  $m_W$  given by (8).

3.  $\hat{\rho}_1 \succ_W \hat{\rho}_2$  if and only if  $W_1 \succ_t W_2$ , namely if there exists a kernel k of the form (33) such that

$$W_2(\boldsymbol{r}) = \int d\boldsymbol{z} k(\boldsymbol{r}, \boldsymbol{z}) W_1(\boldsymbol{z}) \,. \tag{38}$$

We comment first on Proposal 1. Since for Wigner functions which are not generically positive the integral of |W| over the entire phase space is not one, we do not impose the condition (12). Thus, the Wigner majorization (in the non-positive case) is established by the weak majorization  $\gg$  defined in Sec. II A (which in the positive case becomes the majorization  $\succ$  due to |W| = W and unit normalization). The main virtue of Proposal 1 is that it is convenient to work with. Testing the weak majorization of absolute values of Wigner functions by condition 1 (see the inequality (4)) is simple to do with Mathematica or an equivalent program. In Sec. V A 1, we test this general proposal for Wigner majorization on some exemplary CV states and report the results in Fig. 2.

The motivation for Proposal 2 comes from the DV case investigated by Koukoulekidis and Jennings in [20]. These authors extended the majorization relation between probability vectors to quasiprobability vectors, essentially by first employing the weak majorization criterion (1) which is then promoted to a majorization relation due to the unit normalization of quasiprobability vectors that satisfies (2). In [20] this was phrased as a "heretic" Lorentz curve criterion. A continuous version of the heretic Lorentz curve criterion would be to find an extension of the majorization condition 4 (see (9) and (10)) by finding a way to construct decreasing rearrangements for non-positive functions. However, this attempt leads to pathologies. Instead, a more fruitful approach is to construct extensions of the majorization conditions 1 and 3. Extension to non-positive functions leads to divergent integrals. However, the integrals appearing in the definition are divergent separately, but in Sec. VA2 we show that, under certain (quite natural) circumstances, the divergences are crucially canceled out once we consider the differences in (36) and (37) (see also Fig. 3).

Finally, Proposal 3 is slightly different from the previous two since it establishes that a CV state  $\hat{\rho}_1$  majorizes  $\hat{\rho}_2$  whenever the latter is obtained from the former via a Gaussian channel. Thus, this definition tautologically induces a counterpart of Nielsen's theorem for Wigner majorization and Gaussian channels. Due to this property, we dub this relation *tautological majorization*, which explains the index t below the symbol  $\succ$  in the text above (38). To show that this relation can be legitimately called majorization, in Appendix C we show that it realizes a preorder, as the usual continuous majorization. It would then provide a preorder for the resource theories of Wigner negativity and non-Gaussianity, where the input always majorizes the output under free (Gaussian) operations.

Note that while Proposals 1 and 3 hold for any CV state with absolutely integrable Wigner function, Proposal 2 has a more restricted range of validity due to an additional technical condition on the Wigner functions required for the integrals in (36) and (37) to be well-defined (see Sec. V A 2 for more details). Note further that Proposals 1 and 2 reduce to the Wigner majorization discussed in Sec. II A when applied to CV states with positive Wigner functions. This does not happen for Proposal 3, which has a different behavior also when considered on Wigner-positive states, as discussed in Sec. V A 3. Finally, a natural question to ask is if or when Proposals 1 and 2 are equivalent. We leave this for future work.

The three generalizations listed above have an important common feature concerning the Wigner logarithmic negativity. Given a CV state  $\hat{\rho}$  with Wigner function  $W_{\hat{\rho}}$ , the Wigner logarithmic negativity is defined as

$$\mathcal{N}_{W_{\hat{\rho}}} \equiv \ln\left(\int |W_{\hat{\rho}}(\boldsymbol{r})| d\boldsymbol{r}\right)$$
 (39)

Due to the normalization (19),  $\mathcal{N}_{W_{\hat{\rho}}}$  is vanishing when  $W_{\hat{\rho}}$  is positive and non-vanishing otherwise. In other words, the Wigner logarithmic negativity measures how much a CV state is not Wigner-positive. This quantity is tightly related to the resource theories of non-Gaussianity and Wigner negativity, and, indeed, it has been proven monotonic under Gaussian protocols [21, 22]. In Sec. V B, we prove the following result, which shows  $\mathcal{N}_{W_{\hat{\rho}}}$  to be an insightful quantity in the context of Wigner majorization.

**Result 9**: Given two CV states  $\hat{\rho}_1$  and  $\hat{\rho}_2$  with Wigner functions  $W_1$  and  $W_2$  respectively, using any of the three generalized Wigner majorization proposals reported in Result 7, we have that

$$\hat{\rho}_1 \succ_{\mathrm{W}} \hat{\rho}_2 \quad \Rightarrow \quad \mathcal{N}_{W_1} \ge \mathcal{N}_{W_2} \,.$$
 (40)

In other words, a Wigner majorization relation between two CV states implies a relation between their Wigner logarithmic negativity. At this point, the exclusion of states with non-absolutely integrable Wigner functions from our analysis can be justified on physical grounds. Indeed, from (39), we see that, if  $W_{\hat{\rho}} \notin L^1(\mathbb{R}^{2N})$ , the corresponding Wigner logarithmic negativity is not defined, implying that the resourcefulness of  $\hat{\rho}$  in the context of the resource theory of Wigner negativity is not well-described. For this reason, we exclude this class of states from our analysis.

The Wigner Rényi entropies are other quantities that can be defined from the Wigner function  $W_{\hat{\rho}}$  of given state  $\hat{\rho}$  and are defined as

$$S_{W_{\hat{\rho}}}^{(\alpha)} = \frac{1}{1-\alpha} \ln\left(\int [W_{\hat{\rho}}(\boldsymbol{r})]^{\alpha} d\boldsymbol{r}\right) \,. \tag{41}$$

While these quantities are finite and real-valued for any  $\alpha > 0$  when  $\hat{\rho}$  is a Wigner-positive state, issues arise in the more general case. In [20] the Wigner Rényi entropies were considered in the DV case. They pointed out that extension to the case of non-positive Wigner functions is finite and real-valued for  $\alpha = 2p/(2q-1)$ , where p and q are positive integers, and established that (41) are non-decreasing for  $\alpha > 1$  under the free operations mapping Wigner-positive states into Wigner-positive states. In Sec. V B we address the question of whether  $S_{W_{\hat{\rho}}}^{(\alpha)}$  is monotonic under Gaussian channels, deriving the following result.

**Result 10:** Consider a CV state  $\hat{\rho}_{in}$  with Wigner function  $W_{in}$  and act on it with a Gaussian channels  $\mathcal{E}$  determined by the matrices X and Y. If we denote the output state as  $\hat{\rho}_{out} = \mathcal{E}(\hat{\rho}_{in})$  and its Wigner function as  $W_{out}$ , the following inequality holds  $\forall \alpha \geq 1$ :

$$(\det X)^{\alpha-1} \int d\boldsymbol{r} \ |W_{\text{out}}(\boldsymbol{r})|^{\alpha} \leq \int d\boldsymbol{r} \ |W_{\text{in}}(\boldsymbol{r})|^{\alpha} .$$
 (42)

When  $\alpha = 1$ , (42) is consistent with the monotonicity of Wigner logarithmic negativity under Gaussian protocols proven in [21, 22]. On the other hand, when  $\alpha > 1$ , the channel-dependent term with the matrix X of the lefthand side of (42) spoils the monotonicity of Wigner Rényi entropies (41) under Gaussian channels: instead we find the inequality

$$-\ln(\det X) + S_{W_{\text{out}}}^{(\alpha)} \ge S_{W_{\text{in}}}^{(\alpha)} \quad , \quad \forall \; \alpha > 1 \; . \tag{43}$$

Thus unlike in the DV case, for CV states there is no monotonicity under Gaussian channels. In Fig. 4 we illustrate with some examples that the Wigner Rényi entropies may increase or decrease under a Gaussian channel, depending on choices of input states and channel parameters. This provides a second difference between Wigner majorizations in DV states and CV states.

To gain more insights on the Wigner majorization between a generic input CV state and the corresponding

output state obtained from applying a Gaussian channel, we focus on Proposal 1 described in Result 8, which proves to be the most versatile and also the easiest to evaluate among the three proposals. In Sec. V C we prove that, when employing this Wigner majorization proposal, Result 7 can be extended to generic, not necessarily Wigner positive, CV states with an absolutely integrable Wigner function.

**Result 11:** The class of Gaussian channels  $\mathcal{E}_{X,Y}$  characterized by the matrices X and Y such that det X = 1 is a class of Wigner-majorizing channels when applied to generic CV states, namely, for any CV state  $\hat{\rho}$ ,

$$\hat{\rho} \succ_{\mathrm{W}} \mathcal{E}_{X,Y}(\hat{\rho}) \,. \tag{44}$$

So far, when considering quantum operations, we have focused on Gaussian channels. To discuss different instances, we consider the quantum operation defined by the following action on a density matrix  $\hat{\rho}$  of a CV state

$$\mathcal{E}_{p}(\hat{\rho}) = \int dS \int d\bar{\boldsymbol{r}} \, p(S, \bar{\boldsymbol{r}}) U_{S, \bar{\boldsymbol{r}}} \hat{\rho} U_{S, \bar{\boldsymbol{r}}}^{\dagger} \,, \qquad (45)$$

where the integral over  $\bar{r}$  is performed over the entire phase space, while the integral over S is performed over the set of symplectic matrices corresponding to the Gaussian unitaries applied to  $\hat{\rho}$ . Examples of channels in this class have been considered in [38, 39] and their quantum capacity has been studied. The transformation in (45) amounts to apply on the input state random combinations  $U_{S,\bar{r}}$  of Gaussian unitary transformations and displacements distributed according to the probability density function  $p(S, \bar{r})$ . For this reason, we call the channel  $\mathcal{E}_p$  random Gaussian unitary channel. By focusing again on the Wigner majorization proposal 1 in Result 8, in Sec. VC, we prove that any CV state with an absolutely integrable Wigner function after the application of a random Gaussian unitary channel is majorized by the corresponding input state.

**Result 12:** For any CV state and any choice of channel of the form (45) we have that

$$\hat{\rho} \succ_{\mathrm{W}} \mathcal{E}_p(\hat{\rho}) \,. \tag{46}$$

Note that this result can be viewed as a quantum phase space counterpart of Uhlmann's theorem of (density matrix) majorization. The latter states that the output state of any unital channel, i.e. a quantum channel that maps the identity into itself, is always density matrix-majorized by the corresponding input state [40]. Furthermore, since random Gaussian unitary channels  $\mathcal{E}_p$  in (45) are also examples of unital channels, Uhlmann's theorem of majorization should also be applicable along with Result 12 (*i.e.*, also  $\hat{\rho} \succ_{\text{DM}} \mathcal{E}_p(\hat{\rho})$  holds). A heuristic interpretation of Result 12 is that random Gaussian unitary channels (at least, random displacement channels) are models of bosonic noise, and, according to Result 12, the Wigner function of the output state is a "more random" distribution in quantum phase space than that of the input state. We conclude by mentioning notable examples of random Gaussian unitary channels. If we restrict to pure displacements, namely  $U_{S,\bar{r}} = U_{\bar{r}}$ , the resulting operation in (45) is a random displacement channel and, if we further consider  $p(\bar{r})$  to be a Gaussian distribution, we obtain the classical mixing channels mentioned in Sec. II B.

# III. CONTINUOUS MAJORIZATION AND POSITIVE WIGNER FUNCTIONS

In this section, we study the Wigner majorization between Wigner positive states, focusing on Gaussian states. Exploiting known results in the theory of majorization between probability distributions, we provide a criterion for Wigner majorization of Gaussian states. This condition allows analytic control on the Wigner majorization properties of a large class of continuously parametrized families of Gaussian states, which includes examples of physical relevance, such as thermal states of harmonic chains. We finally discuss a quantitative comparison between the Wigner majorization and the density matrix majorization for single- and two-mode Gaussian states.

#### A. Wigner majorization of Gaussian states

The theory of majorization between Gaussian probability distributions has been discussed in detail in [27], where it has been found that, given two Gaussian distributions  $f_{\Sigma_1}$  and  $f_{\Sigma_2}$  with covariance matrices  $\Sigma_1$  and  $\Sigma_2$  respectively,  $f_{\Sigma_1}\succ f_{\Sigma_2}$  according to the definition reviewed in Sec. II A if and only if det  $\Sigma_1 \leq \det \Sigma_2$ . This result immediately applies to the Wigner majorization between Gaussian states with covariance matrices  $\gamma_1$  and  $\gamma_2$  constrained by (23). Indeed, recalling that the Wigner function of an N-mode Gaussian state is a Gaussian distribution with 2N variables, recalling the definition of Wigner majorization in Sec. IIA, we straightforwardly obtain Result 1 in Sec. IIB. Let us discuss some of the implications of this result. Consider two generic Gaussian states characterised by their covariance matrices  $\gamma_1$ and  $\gamma_2$  and whose corresponding Wigner functions  $W_1$ and  $W_2$  are obtained from (21). Result 1 implies that  $W_1 \succ W_2$  when det  $\gamma_1 \leq \det \gamma_2$ , where

$$\det \gamma = \prod_{j=1}^{N} \sigma_j^2 \ge \frac{1}{4^N} , \qquad (47)$$

which can be obtained by combining (24) with the fact that det S = 1 for any real symplectic matrix S. The determinant of the covariance matrix is largely studied given its relation with various quantities such as the purity [3], the Shannon entropy of Wigner functions [41, 42] and the entropy of outcomes of Gaussian measurements [43]. In the context of Wigner majorization, det  $\gamma$  allows to conclude that the preorder between two Gaussian states is determined only by the symplectic spectra of the corresponding covariance matrices and the Wigner function majorization between Gaussian states provides a *total* preorder, namely either  $W_1 \succ W_2$  or  $W_2 \succ W_1$  for any given pair of Wigner functions  $W_1$  and  $W_2$ .

The above mentioned sufficient condition for the Wigner majorization implies that any monotonically decreasing function of det  $\gamma$  preserves the majorization relation. i.e. it is Schur convex from the point of view of the Wigner function majorization. An interesting example is the purity  $\text{Tr}(\hat{\rho}^2)$ , satisfying  $\text{Tr}(\hat{\rho}^2) \leq 1$  for any normalised quantum state, which is saturated only by the pure states. The purity of a Gaussian state is determined by det  $\gamma$  as follows [3]

$$\operatorname{Tr}(\hat{\rho}^2) = \frac{1}{2^N \sqrt{\det \gamma}}, \qquad (48)$$

where the prefactor depends on the convention adopted in the definition of the covariance matrix. This is consistent with the interpretation of the majorization in terms of the mixedness of a state; indeed, if a state majorizes another state, it is less mixed and, correspondingly, its purity is larger.

We find it instructive to consider also the second Rényi entropy  $S^{(2)}(\hat{\rho}) \equiv -\ln \operatorname{Tr}(\hat{\rho}^2)$ . In the case of a bosonic Gaussian state, from (48) one finds

$$S^{(2)}(\hat{\rho}) = N \ln 2 + \frac{1}{2} \ln \det \gamma = \sum_{j=1}^{N} \ln(2\sigma_j), \qquad (49)$$

which is an increasing function of det  $\gamma$ . Thus, by applying the conclusions of discussion above, for two bosonic Gaussian states  $\hat{\rho}_1$  and  $\hat{\rho}_2$  we have that

$$\hat{\rho}_1 \succ_{\mathrm{W}} \hat{\rho}_2 \quad \Leftrightarrow \quad S^{(2)}(\hat{\rho}_1) \le S^{(2)}(\hat{\rho}_2), \qquad (50)$$

meaning that also the second Rényi entropy  $S^{(2)}(\hat{\rho})$  characterises the Wigner majorization relation between two Gaussian states in a unique way.

As reviewed in Sec. IIB, the authors of [28] conjectured that the pure state  $\hat{\rho}_0$  given by (25) with  $\sigma_i = 1/2$ . for any j = 1, ..., N, Wigner majorizes any other CV Wigner-positive state. This conjecture was verified in [44] for Wigner positive mixtures of Fock states. Aiming to find more evidences for this conjecture, Result 1 allows to prove this conjecture for the states contained in the convex-hull of N-mode Gaussian states. This claim is the content of Result 2 that we prove in the following. For this purpose, we need to show that  $W_{\hat{\rho}_0} \succ W_{\hat{\rho}}$ , where  $W_{\hat{\rho}_0}$  is the Wigner function of the pure state  $\hat{\rho}_0$  and  $W_{\hat{\rho}}$ the one of the generic state in the convex hull defined in (28). First we observe that  $\hat{\rho}_0$  Wigner majorizes any other Gaussian states, given that the determinant of the covariance matrices of pure states is the smallest possible. Thus, since the states  $\hat{\sigma}_i$  are Gaussian,  $\hat{\rho}_0 \succ_{\mathrm{W}} \hat{\sigma}_i$ . At this point, we only have to show that every convex combination of  $\hat{\sigma}_i$  is Wigner majorized by  $\hat{\rho}_0$ . Given the state  $\hat{\rho}$  defined in (28), its Wigner function can be written in terms of the Wigner functions of the states  $\hat{\sigma}_i$  as

$$W_{\hat{\rho}} = \sum_{i} p_i W_{\hat{\sigma}_i} \,. \tag{51}$$

Thus, to prove the Wigner majorization, we have to prove that

$$\int \Phi\left(\sum_{i} p_{i} W_{\hat{\sigma}_{i}}\right) d\boldsymbol{r} \leq \int \Phi(W_{\hat{\rho}_{0}}) d\boldsymbol{r}$$
(52)

for any positive function  $\Phi : [0, \infty) \to [0, \infty)$  which is also convex and non-increasing. Since  $\Phi$  is convex, we can apply Jensen's inequality, obtaining

$$\int \Phi\left(\sum_{i} p_{i} W_{\hat{\sigma}_{i}}\right) d\boldsymbol{r} \leq \sum_{i} p_{i} \int \Phi\left(W_{\hat{\sigma}_{i}}\right) d\boldsymbol{r} \,. \tag{53}$$

Crucially, since  $\hat{\rho}_0 \succ_w \hat{\sigma}_i$  for any  $\hat{\sigma}_i$ , we have that

$$\int \Phi\left(W_{\hat{\sigma}_{i}}\right) d\boldsymbol{r} \leq \int \Phi(W_{\hat{\rho}_{0}}) d\boldsymbol{r} , \qquad (54)$$

which, combined with the fact that  $\sum_{i} p_i = 1$  and (53), leads to (52), concluding the proof of Result 2.

Finally, to showcase the applicability of Result 1, we derive Result 3, which provides a criterion to identify a Wigner majorization order along certain continuously parametrized families of Gaussian states. Exploiting this finding, in the next subsection we discuss concrete physical examples for systems of coupled oscillators.

Considering a one-parameter family of Gaussian density matrices  $\hat{\rho}(\tau)$ , parameterised by the real parameter  $\tau$ , from (47) it is straightforward to prove Result 3 in Sec. II B (see (29)). Indeed, taking first the logarithm of (47) and then its derivative w.r.t.  $\tau$ , we find

$$\partial_{\tau} \det \gamma(\tau) = 2 \det \gamma(\tau) \sum_{k=1}^{\infty} \frac{\partial_{\tau} \sigma_k(\tau)}{\sigma_k(\tau)} \,. \tag{55}$$

Hence the condition  $\partial_{\tau}\sigma_k(\tau) > 0$  for all values of k implies that det  $\gamma_A(\tau_1) > \det \gamma_A(\tau_2)$  when  $\tau_1 > \tau_2$ . Thus, the above majorization criterion leads to

$$\partial_{\tau}\sigma_k(\tau) > 0, \forall k \Rightarrow W_A(\tau_2) \succ W_A(\tau_1),$$
 (56)

when  $\tau_1 > \tau_2$ , which is equivalent to Result 3 in Sec. II B.

#### B. Examples

The model considered in our examples is the harmonic chain made by N sites, whose Hamiltonian is

$$\widehat{H} = \sum_{i=1}^{N} \left( \frac{1}{2m} \widehat{p}_i^2 + \frac{m\omega^2}{2} \widehat{p}_i^2 \right) + \sum_{\langle i,j \rangle} \frac{\kappa}{2} (\widehat{q}_i - \widehat{q}_j)^2 \,, \quad (57)$$

we can set  $\kappa = 1$  and m = 1 without loss of generality and periodic boundary conditions are imposed. The Hamiltonian (57) can be diagonalised through the standard procedure, which requires to introduce the bosonic creation and annihilation operators  $\hat{b}_k^{\dagger}$  and  $\hat{b}_k$ , and the result is

$$\widehat{H} = \sum_{k=1}^{N} \Omega_k \left( \hat{b}_k^{\dagger} \hat{b}_k + \frac{1}{2} \right) \,, \tag{58}$$

where the dispersion relation  $\Omega_k > 0$  for the periodic boundary conditions reads

$$\Omega_k = \sqrt{\omega^2 + 4[\sin(\pi k/N)]^2}, \qquad (59)$$

with  $k = 1, \ldots, N$ .

When the harmonic chain (57) is at finite inverse temperature  $\beta$ , its density matrix is

$$\hat{\rho}_{\rm th} \propto e^{-\beta H}$$
 (60)

In this case the symplectic spectrum is given by

$$\sigma_{\mathrm{th},k} = \frac{1}{2} \coth(\beta \Omega_k/2), \qquad (61)$$

where k = 1, ..., N, which provides the determinant of the corresponding covariance matrix through (47).

For any given value of k = 1, ..., N, the symplectic eigenvalue  $\sigma_{\text{th},k}$  is a decreasing function of  $\beta$ , hence

$$\sigma_{\mathrm{th},k}(T_1) > \sigma_{\mathrm{th},k}(T_2), \quad \text{if } T_1 > T_2, \quad (62)$$

Thus, Result 3 in Sec. II B implies that

$$\hat{\rho}_{T_2} \succ_{w} \hat{\rho}_{T_1}, \quad \text{if } T_1 > T_2, \quad (63)$$

in agreement with the fact that the interpretation of the majorization order is related to the degree of mixedness of the states and that the pure states majorize all the other states.

Another majorization relation is obtained by considering two states at the same temperature and different values of  $\omega$  in their dispersion relation (59). Since

$$\sigma_{\mathrm{th},k}(\omega_1) < \sigma_{\mathrm{th},k}(\omega_2), \qquad \text{if } \omega_1 > \omega_2, \qquad (64)$$

the same analysis leads to

$$\hat{\rho}_{\omega_1} \succ_{\mathrm{W}} \hat{\rho}_{\omega_2}, \quad \text{if } \omega_1 > \omega_2.$$

$$(65)$$

This agrees with the result discussed in the Appendix C of [45], where the density matrix majorization analysis has been performed for the mixed states given by the reduced density matrices of half infinite chains having different frequencies in their dispersion relation.

# C. Comparison with density matrix majorization

Wigner majorization is not the only majorization relation between quantum states introduced in the literature. The density matrix majorization defined in Sec. II A has been widely employed in the study of entanglement and, more generally, in the context of resource theory. In this section, we discuss a comparison between the density matrix majorization and the Wigner majorization. Although not fully general, the analysis in the context of Gaussian states allows to draw insightful conclusions.

#### 1. Density matrix majorization between Gaussian states

To discuss the density matrix majorization properties, we recall that the density matrix of any N-mode Gaussian state can be written in the following form

$$\hat{\rho} = \frac{e^{-\sum_{k=1}^{N} \varepsilon_k \hat{n}_k}}{Z} \,, \tag{66}$$

where  $\hat{n}_k$  are bosonic number operators and  $\varepsilon_k > 0$  are called single-particle energies. The  $\varepsilon_k$ s can be expressed in terms of the symplectic eigenvalues  $\sigma_k$  of the same Gaussian state as

$$\varepsilon_k = \log\left(\frac{\sigma_k + \frac{1}{2}}{\sigma_k - \frac{1}{2}}\right) \,. \tag{67}$$

The normalization factor Z in (66) can be written in terms of single-particle energies as

$$Z = \prod_{k=1}^{N} \frac{1}{1 - e^{-\varepsilon_k}} \,. \tag{68}$$

From (66), the eigenvalues of  $\hat{\rho}$  are

$$\lambda(n_1, n_2, \dots, n_N) = \prod_{k=1}^N (1 - e^{-\varepsilon_k}) e^{-\varepsilon_k n_k} \equiv \prod_{k=1}^N \lambda_k(n_k) ,$$
(69)

where  $n_k$  are the non-negative integer occupation numbers of the different modes. If  $\hat{\rho}$  in (66) depends on a continuous parameter  $\tau$ , i.e.  $\hat{\rho}(\tau)$ , through the singleparticle energies  $\varepsilon_k(\tau)$ , a dependence on  $\tau$  is induced also in the symplectic eigenvalues  $\sigma_k(\tau)$ , in the density matrix eigenvalues  $\lambda(n_1, n_2, \ldots, n_N; \tau)$  and in the k-th mode contribution  $\lambda_k(n_k; \tau)$ . Notice that each eigenvalue in (69) depends on N occupation numbers; hence it is difficult to order the elements of the spectrum of  $\hat{\rho}$  to directly check the density matrix majorization. To overcome this difficulty, we exploit the factorized structure of  $\lambda(n_1, n_2, \ldots, n_N; \tau)$ . Indeed, a result proved in [46] claims that, if, for any pair  $\tau_1 > \tau_2$ , we have

$$\sum_{n_k=0}^{m} \lambda_k(n_k, \tau_1) \ge \sum_{n_k=0}^{m} \lambda_k(n_k, \tau_2), \quad \forall m \ge 0, \ 1 \le k \le N$$
(70)

then

$$\hat{\rho}(\tau_1) \succ_{\text{DM}} \hat{\rho}(\tau_2) \,. \tag{71}$$

In other words, the density matrix majorization can be proved by checking the condition (1) for every mode. Exploiting the exponential form in (69), after a bit of algebra, we can show that (70) is satisfied if  $\partial_{\tau} \varepsilon_k(\tau) > 0$ . Using that (67) is a monotonically decreasing function and (70)-(71), we conclude that

$$\partial_{\tau}\sigma_{k}(\tau) < 0, \; \forall k, \; \forall \tau_{1} \geq \tau \geq \tau_{2} \; \Rightarrow \; \hat{\rho}_{\tau_{1}} \succ_{\text{DM}} \hat{\rho}_{\tau_{2}}.$$
(72)

FIG. 1: Differences of the partial sums (76) of eigenvalues of density matrices representing two-mode Gaussian states as functions of the number m of terms involved in partial sums. The data are reported for five pairs of Gaussian states, whose symplectic eigenvalues are displayed in the parametrization (74). When one of the curves crosses the horizontal axis, the density matrix majorization between the two corresponding Gaussian states is ruled out.

This result generalizes the one derived in Appendix C of [45], where this analysis was restricted to the reduced density matrix of half harmonic chain and the parameter  $\tau$  was the frequency parameter. The result (72) holds more generally for any family of Gaussian states continuously parameterized. As a corollary of (72), given a pair of states  $\hat{\rho}_1$  and  $\hat{\rho}_2$  with symplectic eigenvalues  $\sigma_k^{(1)}$  and  $\sigma_k^{(2)}$  respectively, with label k enumerating the eigenvalues in descending order, if  $\sigma_k^{(1)} < \sigma_k^{(2)}$  for any k, then  $\hat{\rho}_1 \succ_{\rm W} \hat{\rho}_2$  and  $\hat{\rho}_1 \succ_{\rm DM} \hat{\rho}_2$ .

Our conclusion allows a first comparison between Wigner majorization and density matrix majorization. Indeed, comparing (29) and (72), we notice that, given a family of Gaussian states parametrized by  $\tau$ , if  $\partial_{\tau}\sigma_k(\tau) < 0$  for any k, then we have both Wigner and density matrix majorization order along the line parameterized by  $\tau$ . Since the single-mode Gaussian states are completely specified by their unique symplectic eigenvalue, when applied to this class of states, this comparison establishes the equivalence between density matrix majorization and Wigner majorization, which corresponds to Result 4.

#### 2. Majorization analysis of two-mode Gaussian states

To understand whether the equivalence between Wigner majorization and density matrix majorization holds for N-mode Gaussian states with N > 1, it is insightful to examine the case of two-mode Gaussian states. Since Gaussian states are considered, the Wigner majorization is established through their second Renyi entropies, according to the criterion given in (50). As for the density matrix majorization, the eigenvalues (69) must be considered. When N = 2, these eigenvalues depend on two occupation numbers and read

$$\lambda(n_1, n_2) = \frac{1}{\sigma_1 + \frac{1}{2}} \frac{1}{\sigma_2 + \frac{1}{2}} \left(\frac{\sigma_1 - \frac{1}{2}}{\sigma_1 + \frac{1}{2}}\right)^{n_1} \left(\frac{\sigma_2 - \frac{1}{2}}{\sigma_2 + \frac{1}{2}}\right)^{n_2},$$
(73)

where also (67) has been exploited. For the forthcoming analysis, a convenient parametrization of the two symplectic eigenvalues is

$$\sigma_1 = av, \qquad \sigma_2 = \frac{a}{v}. \tag{74}$$

where a and v are positive and such that  $\sigma_1, \sigma_2 > 1/2$ . In this parametrization,  $S^{(2)}$  reads

$$S^{(2)}(\hat{\rho}) = \log 4 + \log(\sigma_1 \sigma_2) = 2\log(2a), \quad (75)$$

namely a parametrizes the contribution of the symplectic spectrum to  $S^{(2)}$ . In particular, given two states  $\hat{\rho}_{\sigma}$ and  $\hat{\rho}_{\tau}$  with symplectic spectra parameterized by  $(a_{\sigma}, v_{\sigma})$ and  $(a_{\tau}, v_{\tau})$  respectively, from (50) we have that  $a_{\tau} \geq a_{\sigma}$ implies  $\hat{\rho}_{\sigma} \succ_{W} \hat{\rho}_{\tau}$ . Checking whether there is a density matrix majorization relation between  $\hat{\rho}_{\sigma}$  and  $\hat{\rho}_{\tau}$  is more complicated because the eigenvalues (73) and their partial sums have to be studied. The density matrix majorization between two states can be ruled out by applying the following procedure.

- 1. Compute the first  $\mathcal{N}$  elements of the spectra of  $\hat{\rho}_{\sigma}$ and  $\hat{\rho}_{\tau}$  by using (73) and order them in a decreasing way  $\left\{\lambda_{i}^{(\sigma)}\right\}_{i=1}^{\mathcal{N}}$  and  $\left\{\lambda_{i}^{(\tau)}\right\}_{i=1}^{\mathcal{N}}$ .
- 2. Compute the first  $\mathcal{N}$  partial sums for the two states, i.e.

$$T_m^{(\sigma)} = \sum_{j=1}^m \kappa_j^{(\sigma)}, \quad T_m^{(\tau)} = \sum_{j=1}^m \kappa_j^{(\tau)}, \quad m = 1, \dots, \mathcal{N}.$$
(76)

3. Compute  $T_m^{(\sigma)} - T_m^{(\tau)}$  and study its sign as a function of m.

The outcome of an analysis performed following these points is reported in Fig. 1, where the differences between the partial sums  $T_m^{(\sigma)}$  and  $T_m^{(\tau)}$  in (76) are reported for five pairs of two-mode Gaussian states  $\hat{\rho}_{\sigma}$  and  $\hat{\rho}_{\tau}$  as a function of the number m of eigenvalues included. All the pairs of states are chosen in such a way that  $a_{\tau} > a_{\sigma}$ , which implies  $\hat{\rho}_{\sigma} \succ_{W} \hat{\rho}_{\tau}$ . On the other hand, we see that four of the five curves in the figure cross the horizontal axis, meaning that  $T_m^{(\sigma)} - T_m^{(\tau)}$  has no definite sign. Thus, we can rule out the density matrix majorization between the corresponding pairs of states and, consequently, the equivalence between Wigner majorization and density matrix majorization in the case of N-mode Gaussian states with N > 1. We find it worth noticing that a detailed analysis of the density matrix majorization between two-mode pure Gaussian states was reported in [33]. The results of [33] are a promising starting point for classifying the N-mode Gaussian states for which density matrix and Wigner majorizations are equivalent, as it happens for the entire set of single-mode Gaussian states.

# IV. WIGNER MAJORIZATION AND QUANTUM CHANNELS

Density matrix majorization is relevant for establishing the existence of quantum channels connecting two quantum states. Motivated by this application, we want to understand whether similar insights can be drawn also through the Wigner majorization. For this purpose, in this section we study the Wigner majorization order between two states related by a Gaussian channel and whether the occurrence of a Wigner majorization relation implies the existence of Gaussian channels connecting two states. These investigations could be of interest in view of applying Wigner majorization to the resource theories of Wigner negativity and non-Gaussianity [21, 22].

# A. Wigner majorization between input and output states

We begin our analysis with a single-mode Gaussian state example, which teaches us an interesting lesson on Wigner majorization. Consider the single-mode Gaussian channel whose action on the input single-mode Gaussian state is given by (31) with [47, 48]

$$X = \sqrt{1 - s} \mathbf{1}_2, \qquad \qquad Y = sc \mathbf{1}_2, \qquad (77)$$

where  $s \in [0, 1]$ ,  $c \geq 1/2$  and  $\mathbf{1}_2$  is the  $2 \times 2$  identity matrix. The channel defined by (77) is called *thermal noise channel* and physically describes an operation that preserves the initial state with probability 1 - s and with probability s replaces it with a thermal state with symplectic eigenvalue c. Given an input single-mode Gaussian state with covariance matrix  $\gamma_{in}$  and unique symplectic eigenvalue  $\sigma_{in}$ , after applying a thermal noise channel we have

$$\gamma_{\rm in} \mapsto \gamma_{\rm out} \equiv (1-s)\gamma_{\rm in} + sc\mathbf{1}_2 \quad \Rightarrow \quad \sigma_{\rm out} = (1-s)\sigma_{\rm in} + sc \,, \tag{78}$$

where  $\gamma_{\scriptscriptstyle \rm out}$  is the covariance matrix of the output state and  $\sigma_{out}$  its symplectic eigenvalue. It is straightforward to notice that  $\sigma_{\scriptscriptstyle \rm out}~\geq~\sigma_{\scriptscriptstyle \rm in}$  if  $c~\geq~\sigma_{\scriptscriptstyle \rm in}$  and, otherwise, we have  $\sigma_{\rm in} > \sigma_{\rm out}$ . By (27) we have that the input state Wigner majorizes the output if  $\sigma_{out} \geq \sigma_{in}$  and, vice-versa, the output Wigner majorizes the input when  $\sigma_{\rm in} \geq \sigma_{\rm out}$ . For instance, if the input state is thermal with  $\sigma_{\rm in} = \coth(\beta \Omega/2)$  (see (61)), it is necessary to mix it with a hotter state in order to have that the input state Wigner majorizes the output state, moving towards more disorder, as intuitively expected. On the other hand, if we choose to mix the input state with a colder state, the opposite situation occurs. We conclude that, in general, there is no fixed majorization order between a given state and the output state after applying a Gaussian channel. This counterexample confirms Result 5.

Result 5 provides a first remarkable difference between the Wigner majorization among CV and DV states, as discussed in Sec. IIB. Indeed, in [20], considering states defined on finite-dimensional Hilbert spaces, channels mapping Wigner positive states to Wigner positive states are studied by employing the Wigner majorization. We refer to this class of channels as *positivity-preserving* channels. It has been found that any output state obtained by applying this class of channels is always Wigner majorized by the corresponding input state. This result has been obtained by using the C-J isomorphism [35, 36] mapping any quantum channel into a quantum state defined on an extended Hilbert space. Indeed, the channels in [20] are expressed in terms of the Wigner function of the corresponding Choi state. Motivated by this approach, the following analysis aims to recast the information on Gaussian channels acting on CV states in a suitable Wigner function. Indeed, the Gaussian channels considered here map Wigner-positive states into Wignerpositive states and, therefore, can be thought of as a subclass of positivity-preserving channels for CV systems.

In the following, we show that by writing the kernel k in (32) as a function on a doubled phase space, we do not obtain the same Wigner function as the one obtained from the regularized C-J isomorphism. We begin by rewriting the kernel k, which connects input and output Wigner functions, as a function on a doubled phase space parametrized by  $\boldsymbol{\zeta} \equiv (\boldsymbol{r}, \boldsymbol{z})^{\text{t}}$ . It is straightforward to find

$$k(\boldsymbol{\zeta}) \equiv \frac{e^{-\frac{1}{2}\boldsymbol{\zeta}^{\mathrm{t}}\Gamma^{-1}\boldsymbol{\zeta}}}{(2\pi)^{N}\sqrt{\det Y}}, \quad \Gamma^{-1} = \begin{pmatrix} Y^{-1} & -Y^{-1}X\\ -X^{\mathrm{t}}Y^{-1} & X^{\mathrm{t}}Y^{-1}X \end{pmatrix}$$
(79)

Notice that  $\Gamma^{-1}$  is well-defined, but  $\Gamma = (\Gamma^{-1})^{-1}$  is not because det  $\Gamma^{-1} = 0$ . This hampers the interpretation of k as a Gaussian Wigner function on a doubled phase space. At this point, we apply the C-J isomorphism to the Gaussian channel characterized by the matrices X and Y. The rough idea is to associate with this channel a Choi state defined on two copies of the Hilbert space where the channel acts. A more detailed description is reported in Appendix B. Once the CV Choi state is determined, it can be described in terms of its Wigner function, which is defined on a doubled version of the original quantum phase space. For the considered Gaussian channel (see the definition in (31)), the Wigner function of the corresponding Choi state reads [1]

$$W_C(\boldsymbol{R}) = \frac{e^{-\frac{1}{2}\boldsymbol{R}^{\mathrm{t}}\gamma_C^{-1}\boldsymbol{R}}}{(2\pi)^{2N}\sqrt{\det\gamma_C}}, \qquad \boldsymbol{R} \equiv (\boldsymbol{r}, \boldsymbol{r}^{\mathrm{aux}})^{\mathrm{t}},$$
(80)

where

$$\gamma_C = \lim_{\nu \to \infty} \begin{pmatrix} \cosh(2\nu)XX^{\mathrm{t}} + Y & \sinh(2\nu)X\Sigma_n \\ \sinh(2\nu)\Sigma_nX^{\mathrm{t}} & \cosh(2\nu)\mathbf{1}_{2N} \end{pmatrix},$$

and

$$\Sigma_n \equiv \bigoplus_{j=1}^N \begin{pmatrix} 1 & 0\\ 0 & -1 \end{pmatrix}.$$
 (81)

The vector  $\boldsymbol{R}$  has 4N entries and parametrizes the doubled quantum phase space where the Wigner function of

the Choi state is defined. The parameter  $\nu$  in (81) plays the role of a regulator that must be introduced because the maximally mixed state in CV systems entering the definition of the C-J map is not normalizable. The fact that the limit in (81) does not exist is indeed a manifestation of the non-normalizability of the maximally mixed state. We can now conclude that the regularized Choi Wigner function (80) is different from (79).

The marginal role played by the C-J isomorphism in representing a Gaussian channel as a Wigner function on a doubled phase space is a further manifestation of the difference between CV and DV systems. This fact is also reflected in the different behaviour described in this section of positivity-preserving channels with respect to Wigner majorization.

### B. A class of majorizing Gaussian channels

In the previous subsection, we discussed the absence of a definite Wigner majorization order between input and output states obtained by applying Gaussian channels on CV states. At this point, it is a natural question to ask whether we can identify a class of *Wigner-majorizing* Gaussian channels. A Gaussian channel  $\mathcal{E}$  belongs to this class if  $\hat{\rho}_{in} \succ_{W} \mathcal{E}(\hat{\rho}_{in})$  for any input state  $\hat{\rho}_{in}$ . For this purpose, we exploit (32)-(33), which tell how the Wigner function of a given input state (not necessarily Gaussian) transforms under Gaussian channels.

Consider a Wigner-positive input state  $\hat{\rho}_{in}$  and the output state  $\hat{\rho}_{out} \equiv \mathcal{E}(\hat{\rho}_{in})$  obtained after the application of the Gaussian channel  $\mathcal{E}$ . Let us call  $W_{\text{in}}$  and  $W_{\text{out}}$  the corresponding positive Wigner functions. As discussed in Sec. IIB, if  $W_{in}$  and  $W_{out}$  are related as in (13), then  $W_{\rm in} \succ W_{\rm out}$ , and therefore  $\hat{\rho}_{\rm in} \succ_{\rm W} \hat{\rho}_{\rm out}$  whenever the kernel k in (13) is bistochastic, according to the condition (14). Result 6 in Sec. IIB shows that the kernel (34) is not in general bistochastic. However, by choosing Gaussian channels with det X = 1, (34) becomes bistochastic, and the relation (32) between input and output Wigner functions is consistent with the condition (13). Exploiting this observation, we obtain Result 7, i.e. the fact that the Gaussian channels with  $\det X = 1$  are Wigner-majorizing when applied to Wigner-positive states and, therefore, all the output states obtained from these Gaussian channels are majorized by the corresponding Wigner-positive input states. In Sec. VC, we generalize Result 7 to any input state, not necessarily Wigner-positive.

Let us analyze examples of Gaussian channels with det X = 1. We first emphasize that the single-mode thermal noise channel defined (77) and discussed in the previous section does not enter this category unless it is the trivial channel. Indeed, in that case, det X = 1 - s, which is equal to one only when s = 0, i.e. for the identity channel. On the contrary, a subclass of channels with det X = 1 is given by the Gaussian unitaries, which have Y = 0 and X symplectic (and therefore with determinant one). This is consistent with our previous remarks since we have stressed that states that differ by symplectic

transformations are majorization-equivalent and mutually majorize each other. Another non-trivial subclass of Wigner-majorizing Gaussian channels contains the *classical mixing channels*. As mentioned in Sec. II B, the classical mixing channels implement on the input state a random displacement of the first moments distributed according to a Gaussian probability density function with a certain covariance matrix Y. Thus, they can be thought of as a special case of (45) with  $U_{S,\bar{r}} = U_{\bar{r}}$  and

$$p(\bar{\boldsymbol{r}}) = \frac{e^{-\frac{1}{2}\bar{\boldsymbol{r}}^{\mathrm{t}}Y^{-1}\bar{\boldsymbol{r}}}}{(2\pi)^{N}\sqrt{\det Y}}.$$
(82)

One can prove that the resulting channel is Gaussian and characterized by the  $2N \times 2N$  matrices  $X = \mathbf{1}$  and Ygiven by the covariance matrix in (82) [1, 47, 48]. From these properties, we find that det X = 1 and, therefore, the classical mixing channels are Wigner majorizing channels. An equivalent argument valid for Gaussian input states can be given. Indeed, in these cases, from (31), the covariance matrix of the input state changes as  $\gamma \mapsto \gamma + Y$  under the action of the classical mixing channel. A straightforward linear algebra analysis allows to check that, since both  $\gamma$  and Y are real, symmetric, and positive definite, we have (see the exercise on page 511 of [49])

$$\det(\gamma + Y) \ge \det \gamma \,. \tag{83}$$

According to the criterion (27), this inequality implies that a Gaussian input state always Wigner majorizes the corresponding output state after a classical mixing channel.

# V. CONTINUOUS MAJORIZATION FOR GENERIC WIGNER FUNCTIONS

In the previous discussione we have explored Wigner majorization relations between Wigner-positive states. In this section, we extend the previous analysis to generic CV states by introducing three proposals to establish a Wigner majorization order among states that are not generically Wigner-positive. This investigation is also motivated by the results of [20], where the Wigner majorization between non Wigner-positive states has been studied for DV systems defined on finite-dimensional Hilbert spaces with odd dimensionality. After discussing the main features of the our proposals, we extend the results of Sec. IV to the case where the input state is a generic CV state with finite Wigner negativity.

# A. Three proposals for general Wigner majorization

Result 8 in Sec. II C introduces three proposal for Wigner majorization relations between CV states with finite, not necessarily vanishing, Wigner negativity. As discussed in Sec. II C, we exclude from our analysis states with non-absolutely integrable Wigner functions. An example in this class of states is the single-mode state with a characteristic function [61]

$$\chi(x,p) = \begin{cases} 1 & \text{if } x \in [-1,1] \text{ and } p \in [-1,1] \\ 0 & \text{otherwise} \end{cases}, \quad (84)$$

which, using (18), leads to

$$W(x,p) = \frac{1}{\pi^2} \frac{\sin x}{x} \frac{\sin p}{p} \,. \tag{85}$$

One can show that the Wigner function (85) is not absolutely integrable. Generally, these states are difficult to understand in the resource theory of Wigner negativity due to their ill-defined resourcefulness. For this reason, our analysis focuses on states with finite Wigner negativity, i.e. with absolutely integrable Wigner functions. In this subsection, we discuss and compare the three generalized Wigner majorization proposals, illustrating also insightful examples.

#### 1. Proposal 1

The absolute value of any Wigner function is a positive function. Thus, we can employ the weak majorization relation  $\gg$  defined by one of the equivalent criteria 1-4 in Sec. II A and induce an order relation among the absolute values of Wigner functions. Notice that we cannot impose the majorization relation  $\succ$  between the absolute values of Wigner functions because their integral over the entire phase space is not equal to one and depends on the considered state. The weak majorization relation  $\gg$  between the absolute values of the Wigner functions of two generic CV states immediately induces the Wigner majorization relation, which we refer to as *Proposal 1* in Result 8. Since the Wigner function of a Wigner-positive state is equal to its absolute value, when evaluated between two Wignerpositive states, Proposal 1 reduces to the usual Wigner majorization employed in Secs. III and IV. Moreover, if two generic CV states differ by a Gaussian unitary, they are majorization equivalent according to this proposal. This is true because the Wigner functions corresponding to these states differ by a symplectic transformation on the phase space coordinates, which preserves the values of integrals as the ones in (4) and (6), which are required to check the Wigner majorization via Proposal 1.

A remarkable feature of Proposal 1 is its simplicity in establishing whether a Wigner majorization relation occurs between two states. In particular, this can be achieved by testing the condition (4) on the absolute value of the Wigner functions of the considered states. For convenience, we introduce the functional

$$I_t[|W_{\hat{\rho}}|] \equiv \int [|W_{\hat{\rho}}(\boldsymbol{r})| - t]_+ d\boldsymbol{r} , \qquad (86)$$

on a generic Wigner function  $W_{\hat{\rho}}$  of the CV state  $\hat{\rho}$ . Comparing with (4), the functional  $I_t$  allows to reformulate the condition 1 for the weak majorization  $|W_1| \gg |W_2|$  as

$$I_t[|W_1|] \ge I_t[|W_2|], \qquad \forall t \ge 0.$$
(87)

In the following, we discuss some examples involving single-mode states. A well-known class of single-mode CV states is made by the eigenstates of a harmonic oscillator. Denoting by  $|n\rangle$  the *n*-th oscillator eigenstate, obtained by acting *n* times on the vacuum state with the creation operator, the Wigner functions of these states are [50]

$$W_{|n\rangle}(x,p) = \frac{(-1)^n}{\pi} e^{-(x^2+p^2)} L_n(2(x^2+p^2)) \quad (88)$$
$$= \frac{(-1)^n}{\pi} e^{-r^2} L_n(2r^2) \equiv W_{|n\rangle}(r) ,$$

where  $L_n$  is the Laguerre polynomial of order n. Notice that  $W_{|n\rangle}$  is a positive function on the phase space only when n = 0 and, therefore, the vacuum state is the only Wigner-positive oscillator eigenstate.

In the left panel of Fig. 2, we show  $I_t$  in (86) as a function of t on the absolute values of oscillator eigenstate Wigner functions (88) for five distinct values of n. All the curves displayed mutually intersect at one point. Exploiting (87) and Proposal 1 in Result 8, we conclude that there is no Wigner majorization order between any pair of oscillator eigenstates. We check this fact for the first fifteen oscillator eigenstates, but only the curves for five of them are shown in the panel to avoid clutter. In the inset of this panel, we report the logarithm of  $I_0[W_{|n\rangle}]$  as a function of  $\ln n$ , where n labels the oscillator eigenstates we study. The behaviour of the data points suggests that  $I_0[W_{|n\rangle}] \sim b n^a$  as  $n \to \infty$ . The coefficients  $a \simeq 0.44$ and  $b \simeq 0.12$  identifying the dashed line in the inset have been found through a fit procedure.

In order to showcase examples of CV states that exhibit Wigner majorization order according to Proposal 1, we construct a mixture of the vacuum state and the first excited state of a harmonic oscillator. The Wigner function of this family of mixed states read

$$\widetilde{W}_{u}(r) = (1-u)W_{|0\rangle}(r) + uW_{|1\rangle}(r),$$
 (89)

where  $W_{|0\rangle}$  and  $W_{|1\rangle}$  are given in (88) and  $u \in [0, 1]$ . The functional  $I_t$  in (86) can be evaluated on the absolute values of  $\widetilde{W}_u$  in (89). The curves obtained for four choices of the parameter u are reported in the right panel of Fig. 2. Differently from the left panel, the four curves do not intersect for any finite values of t. In particular, we find that

$$I_t\left[|\widetilde{W}_1|\right] \ge I_t\left[|\widetilde{W}_{9/10}|\right] \ge I_t\left[|\widetilde{W}_{3/4}|\right] \ge I_t\left[|\widetilde{W}_{3/5}|\right],$$
(90)

 $\forall t \geq 0$ . Using (87), this chain of inequalities implies

$$|\widetilde{W}_1| \gg |\widetilde{W}_{9/10}| \gg |\widetilde{W}_{3/4}| \gg |\widetilde{W}_{3/5}|.$$
(91)

Thus, by employing Proposal 1 in Result 8, we find the following Wigner majorization order

$$\hat{\rho}_{\widetilde{W}_1} \succ_{\mathrm{W}} \hat{\rho}_{\widetilde{W}_{9/10}} \succ_{\mathrm{W}} \hat{\rho}_{\widetilde{W}_{3/4}} \succ_{\mathrm{W}} \hat{\rho}_{\widetilde{W}_{3/5}}.$$
(92)

FIG. 2: Left: The functional in (4) evaluated on the absolute value of the Wigner functions (88) of the harmonic oscillator eigenstates and plotted as a function of t. Five different eigenstates are considered. The fact that each curve intersects all the others indicates the absence of Wigner majorization among these eigenstates. The inset shows  $\ln I_0$  evaluated on the same class of Wigner functions plotted as a function of  $\ln n$ . The dashed line corresponds to  $0.44 \ln n + 0.12$  and is obtained through a fit procedure. Right: The functional in (4) is evaluated on the mixture (89) for four choices of u. The non-intersection of the curves signals the relation  $|\widetilde{W}_1| \gg |\widetilde{W}_{9/10}| \gg |\widetilde{W}_{3/4}| \gg |\widetilde{W}_{3/5}|$  and the consequent Wigner majorization among the considered states.

Looking at (92), we may suspect a Wigner majorization order along the family of states  $\widetilde{W}_u$ . This is not the case, as we can check by comparing, for instance,  $I_t \left[ |\widetilde{W}_{1/10}| \right]$ with any of the functional shown in the right panel of Fig. 2. It would be interesting to identify subsets of  $\widetilde{W}_u$ in which all elements exhibit a Wigner majorization relationship with one another. We leave this question for future works.

The efficiency of Proposal 1 in establishing Wigner majorization relations is exploited later, in the analysis of the Gaussian channels acting on *generic* CV states under the lenses of Wigner majorization.

#### 2. Proposal 2

The functional  $I_t$  evaluated on a positive Wigner function W (without absolute value) diverges when t < 0. Indeed, in this case W - t > 0, hence  $[W - t]_+ = W - t$ and

$$I_t[W] = 1 - t \int d\boldsymbol{r} \,, \tag{93}$$

where the normalization (19) has been used. Crucially, the divergence in (93) is independent of the considered Wigner function. Thus, given two positive Wigner functions  $W_1$  and  $W_2$ , we have that

$$I_t[W_1] - I_t[W_2] = 0, \quad \forall t < 0.$$
(94)

This means that the criterion (4) can be extended to Wigner majorization of positive Wigner functions to any real value of the parameter t. In contrast, if we consider a generic Wigner function W that can take negative values, the functional  $I_t[W]$  still diverges for t < 0, but this divergence depends on the underlying state. Thus, if we aim at introducing a Wigner majorization proposal based on the sign of  $I_t[W_1] - I_t[W_2]$ , as Proposal 2 in Result 8, it is necessary to check that this difference is well-defined for negative values of t.

Given the Wigner function W of a CV state with density matrix  $\hat{\rho}$ , let  $\mathcal{A}_t^{(W)} \subset \mathbb{R}^{2N}$  be the set of points where W < t. Then, the functional  $I_t$  applied to the Wigner function W can be rewritten as

$$I_t[W] = \int_{\bar{\mathcal{A}}_t^{(W)}} (W-t) d\boldsymbol{r} = \int_{\bar{\mathcal{A}}_t^{(W)}} W d\boldsymbol{r} - t \int_{\bar{\mathcal{A}}_t^{(W)}} d\boldsymbol{r} \,, \quad (95)$$

where  $\bar{\mathcal{A}}_t^{(W)} \equiv \mathbb{R}^{2N} \setminus \mathcal{A}_t^{(W)}$ . Since W and its absolute value are integrable on  $\mathbb{R}^{2N}$ , it is so also on  $\bar{\mathcal{A}}_t^{(W)}$  and, therefore, the first term in (95) is finite. The second term can be written as

$$-t \int_{\bar{\mathcal{A}}_{t}^{(W)}} d\boldsymbol{r} = -t \operatorname{Vol} \bar{\mathcal{A}}_{t}^{(W)} = -t \operatorname{Vol} \mathbb{R}^{2N} + t \operatorname{Vol} \mathcal{A}_{t}^{(W)},$$
(96)

(96) where Vol  $\mathcal{M}$  denotes the volume of a subset  $\mathcal{M} \subset \mathbb{R}^{2N}$ of the phase space. Due to the integrability of W, if t > 0, then Vol  $\mathbb{R}^{2N} - \text{Vol } \mathcal{A}_t^{(W)}$  and (96) are finite, leading to a well-defined  $I_t[W]$ . On the other hand, if t < 0, then  $\text{Vol } \mathbb{R}^{2N} - \text{Vol } \mathcal{A}_t^{(W)}$  is infinite, and, in general, we are not guaranteed that  $\text{Vol } \mathcal{A}_t^{(W)}$  is finite. In the following, we assume the validity of this requirement, thus restricting our analysis to those states whose Wigner function satisfies this property. Under this assumption,  $-t \text{ Vol } \mathbb{R}^{2N}$  is the only divergent term in (96) and in (95), which does not depend on W, differently from  $t \text{Vol } \mathcal{A}_t^{(W)}$ . This allows us to conclude that the divergence of  $I_t[W]$  for t < 0 is universal for the class of these CV states. The universality of the divergence of  $I_t[W]$  for negative values of t suggests to introduce the following regularization for the phase space. Let  $\mathbb{R}^{2N}_{\Lambda}$  be a hypercube of linear size  $\Lambda$  or a hypersphere with radius  $\Lambda$ , both centered in the origin of the phase space. The volumes of these spaces as functions of N and of the regulator  $\Lambda$  read respectively

$$\operatorname{Vol} \mathbb{R}^{2N}_{\Lambda} = \Lambda^{2N} , \quad \operatorname{Vol} \mathbb{R}^{2N}_{\Lambda} = \frac{\pi^N}{\Gamma(N+1)} \Lambda^{2N} , \quad (97)$$

We regularize  $I_t[W]$  by replacing  $\mathbb{R}^{2N}$  with  $\mathbb{R}^{2N}_{\Lambda}$  in the functional. Now, for any finite value of  $\Lambda$  the functional  $I_t[W]$  is finite for any  $t \in \mathbb{R}$ . Notice that choosing to regularize  $I_t[W]$  through a cut-off phase space with spherical symmetry is more convenient when W is rotationally invariant. Given two CV states  $\hat{\rho}_{W_1}$  and  $\hat{\rho}_{W_2}$ with Wigner functions  $W_1$  and  $W_2$  respectively, we can rephrase (36) in Result 8 in a more precise way by saying that  $\hat{\rho}_{W_1} \succ_W \hat{\rho}_{W_2}$  if and only if

$$\infty > \lim_{\Lambda \to \infty} I_t[W_1] - I_t[W_2] \ge 0, \quad \forall t \in \mathbb{R}.$$
 (98)

By using (95) and (96), we find that, for any  $t \in \mathbb{R}$ 

$$\lim_{\Lambda \to \infty} I_t[W_1] - I_t[W_2] =$$

$$= t \left( \operatorname{Vol} \mathcal{A}_t^{(W_1)} - \operatorname{Vol} \mathcal{A}_t^{(W_2)} \right)$$

$$+ \int_{\bar{\mathcal{A}}_t^{(W_1)}} W_1 d\boldsymbol{r} - \int_{\bar{\mathcal{A}}_t^{(W_2)}} W_2 d\boldsymbol{r} < \infty ,$$
(99)

meaning that the condition (36) of Proposal 2 is welldefined. In the light of the analysis above, we find it worth stressing that Proposal 2 for Wigner majorization, differently from Proposal 1, can be applied only to a subclass of CV states having Wigner functions W such that  $\operatorname{Vol} \mathcal{A}_t^{(W)} < \infty$  for any t < 0. Notably, all the Wigner functions relevant for this manuscript and, in particular, the ones considered in the following examples satisfy the condition on the finite volume of  $\mathcal{A}_t^{(W)}$  and, therefore, can be compared through Proposal 2 for Wigner majorization.

At this point, we can discuss the main features of Proposal 2 for Wigner majorization between generic CV states. First notice that, similarly to what happens for Proposal 1, Proposal 2 reduces to the usual Wigner majorization introduced in [28] when evaluated on two Wigner-positive states. Moreover, by the same argument discussed in Sec. V A 1 for Proposal 1, two CV states are majorization-equivalent according to Proposal 2 if they differ by a Gaussian unitary transformation, i.e. their Wigner functions differ by a symplectic transformation of the phase space coordinates.

The condition (4) is equivalent to (7), as reviewed in Sec. II A. This equivalence is formally preserved also when t < 0, provided that the integrals in (7) are welldefined. Using the definition (8), we can rewrite the level function  $m_W(t)$  of a given Wigner function W as

$$m_W(t) = \operatorname{Vol} \mathbb{R}^{2N} - \operatorname{Vol} \mathcal{A}_t^{(W)}.$$
(100)

As explained above, if t < 0, (100) is divergent due to the volume of the entire phase space. Indeed, we recall that we are considering CV states with Wigner functions such that  $\operatorname{Vol} \mathcal{A}_t^{(W)} < \infty$  for t < 0. The divergence of (100) when t < 0 makes the integrals in (6) ill-defined in this regime. Thus, to make sense of (6) evaluated on two generic CV states, we first regularize the phase space and, consequently, the integrals of the two level functions, then we consider the differences of the two integrals in (6) and, finally, we remove the regulator verifying that the result is finite for any  $t \in \mathbb{R}$ . If this is true, the condition (37) is well-defined and gives an equivalent criterion for Proposal 2 for Wigner majorization in Result 8. To verify this welldefiniteness, given a CV state with Wigner function W, we introduce a regularized level function

$$m_W^{(\Lambda)}(t) = \operatorname{Vol} \mathbb{R}^{2N}_{\Lambda} - \operatorname{Vol} \mathcal{A}^{(W)}_t, \qquad (101)$$

where, also in this case,  $\mathbb{R}^{2N}_{\Lambda}$  can be either a hypercube or a sphere of linear size  $\Lambda$ , whose volumes are reported in (97). Integrating (101), we have

$$\int_{t}^{\infty} m_{W}^{(\Lambda)}(s) ds = \int_{t}^{\infty} \left[ \operatorname{Vol} \mathbb{R}_{\Lambda}^{2N} - \operatorname{Vol} \mathcal{A}_{s}^{(W)} \right] ds \,.$$
(102)

When t > 0, (102) is finite in the limit  $\Lambda \to \infty$ , as expected from Wigner majorization of Wigner-positive states [28]. On the other hand, when t < 0, we can rewrite (102) as

$$\int_{t}^{\infty} m_{W}^{(\Lambda)}(s)ds = \int_{0}^{\infty} m_{W}^{(\Lambda)}(s)ds + \int_{t}^{0} m_{W}^{(\Lambda)}(s)ds \quad (103)$$
$$= \int_{t}^{0} m_{W}^{(\Lambda)}(s)ds + \text{finite as } \Lambda \to \infty.$$

Using (101), (103) becomes

$$\int_{t}^{\infty} m_{W}^{(\Lambda)}(s) \, ds = -t \operatorname{Vol} \mathbb{R}_{\Lambda}^{2N} + \int_{t}^{0} \operatorname{Vol} \mathcal{A}_{s}^{(W)} ds + \text{finite} \,.$$
(104)

Since Vol  $\mathcal{A}_s^{(W)}$  is finite for the class of states we are considering, the integral in the right-hand side of (104) is always finite, also for  $\Lambda \to \infty$ . Notice that all the Wigner functions are bounded from below and therefore a finite value  $\bar{t}$  exists such that  $\mathcal{A}_{\bar{t}}^{(W)} = \emptyset$  for  $t < \bar{t}$ . In this range for the parameter t, the integral in the right-hand side of (104) is identically zero, and therefore we do not have to worry about the limit  $t \to -\infty$  of this term. The analysis above implies that, in the limit  $\Lambda \to \infty$ , the divergence of the integral (104) is independent of the Wigner function W. Considering again two CV states  $\hat{\rho}_{W_1}$  and  $\hat{\rho}_{W_2}$ , we can compute the difference between the two correspond-

ing integrals (104), obtaining

$$\int_{t}^{\infty} \left( m_{W_1}^{(\Lambda)}(s) - m_{W_2}^{(\Lambda)}(s) \right) ds \qquad (105)$$
$$= \int_{t}^{0} \left( \operatorname{Vol} \mathcal{A}_s^{(W_1)} - \operatorname{Vol} \mathcal{A}_s^{(W_2)} \right) ds + \text{finite terms},$$

which is finite as  $\Lambda \to \infty$ . This result implies that the condition (37) in Proposal 2 is well-defined and can be used to check the Wigner majorization between CV states.

In Fig. 3, the condition (37) is exploited to test Wigner majorization according to Proposal 2. In particular, the difference in (105) is shown as function of t for  $W_1 = W_{|0\rangle}$ and  $W_2 = W_{|1\rangle}$  in the left panel, where  $W_{|n\rangle}$  is given in (88), and for  $W_1 = \widetilde{W}_{3/5}$  and  $W_2 = \widetilde{W}_{9/10}$  in the right panel, with  $\widetilde{W}_u$  defined in (89). The curves are obtained for six distinct values of  $\Lambda$ . In both panels, we observe that when the cut-off  $\Lambda$  is large enough, the curves collapse on an asymptotic curve. From the resulting asymptotic curve in the right panel, we observe that the plotted quantity has a negative sign in the limit  $\Lambda \to \infty$ . Thus, from the condition (37) we conclude that

$$\hat{\rho}_{\widetilde{W}_{9/10}} \succ_{\mathrm{W}} \hat{\rho}_{\widetilde{W}_{3/5}}.$$
(106)

On the other hand, the asymptotic curve in the left panel does not have a definite sign, meaning that the states  $\hat{\rho}_{W_{|0\rangle}}$  and  $\hat{\rho}_{W_{|1\rangle}}$  do not display a Wigner majorization relation according to Proposal 2. Interestingly, both the presence and the absence of a Wigner majorization relation in the cases in Fig. 3 are also found using Proposal 1 (see (92) and Fig. 2). A general proof that Proposal 1 and Proposal 2 lead to the same majorization order is not straightforward; hence we leave this task for future investigations.

# 3. Proposal 3

In Sec. IV A, we show that CV output states obtained after applying a Gaussian channel and their corresponding input states do not have a fixed Wigner majorization relation. As already commented, this behavior differs from what was found in [20] for DV systems defined on finite dimensional Hilbert spaces with odd dimensionality. In that case, the output state obtained by applying a positivity-preserving channel is always Wigner majorized by the corresponding input state. In Result 8 (see Sec. II C), we introduce a majorization relation that, by construction, ensures that every output state obtained by applying a Gaussian channel is Wigner-majorized by the corresponding input state. This can be seen as a generalization of the result of [20] because Gaussian channels are positivity-preserving operations acting on CV systems. Since the fixed Wigner majorization relation between input and output states is built in Proposal 3, we refer to

it as tautological majorization. This proposal applies to any pair of CV states because it requires checking the existence of a Gaussian channel connecting the two considered states. Given that it does not rely on any of the conditions 1-4 in Sec. II A, we are not guaranteed that this relation identifies a preorder and, therefore, a fullfledged majorization relation. In Appendix C we prove that Proposal 3 defines a preorder; hence we can legitimately call it majorization.

We find it worth stressing that requiring this behaviour for the Wigner majorization relation with respect to the action of Gaussian channels introduces substantial differences in comparison with Proposal 1 and Proposal 2. The first main distinction concerns the case of Wignerpositive states. While Proposals 1 and 2 reduce to the Wigner majorization discussed in [28], Proposal 3 does not. This fact becomes evident by considering the following example involving single-mode Gaussian states. In Sec. IV A, we showed that the output state obtained by applying a thermal noise channel is not necessarily majorized by the corresponding input state. Using Proposal 3 instead, by definition, the input state majorizes the output state, and this shows a behavior significantly different from the other proposals.

A further difference from the other proposals emerges when we try to characterize states that are majorizationequivalent through Proposal 3. According to the definition in Result 8,  $W_1$  and  $W_2$  are majorization-equivalent if we can find a reversible Gaussian channel connecting them. As discussed in [51], a Gaussian channel is reversible if and only if Y = 0. Thus, two Wigner functions are majorization-equivalent through Proposal 3 if and only if they are related by a Gaussian unitary channel. This condition is too restrictive for Proposal 1 and Proposal 2. Indeed, the integrals in (4) and (7) are left invariant not only by symplectic transformations. This implies that, from the perspective of Proposals 1 and 2, majorization-equivalent CV states are not always connected by a Gaussian unitary. In addition to the remarkable similarities with the results found in [20], also these differences between Proposal 3 and the other Wigner majorization proposals suggest us to explore in more details these new general majorization criteria.

The last comparison between the three proposals in Result 8 concerns the validity of (11). Exploiting the convexity of the functional (5), we prove that (11) holds for both Proposal 1 and Proposal 2. Proposal 3 requires a more careful analysis. Consider three states with Wigner functions W,  $W_1$  and  $W_2$  such that  $W \succ_t W_1$  and  $W \succ_t W_2$ . We now ask whether  $W \succ_t tW_1 + (1-t)W_2$ , with  $t \in [0, 1]$ . From the majorization relations, we can write

$$tW_1 + (1-t)W_2 = \int d\mathbf{z} [tk_1(\mathbf{r}, \mathbf{z}) + (1-t)k_2(\mathbf{r}, \mathbf{z})]W(\mathbf{z}),$$
(107)

where  $k_1$  and  $k_2$  are the kernels relating W with  $W_1$ and  $W_2$  respectively. If  $k_1$  and  $k_2$  have the form (33),  $tk_1 + (1-t)k_2$  does not, and, therefore, the property (11) does not hold for Proposal 3. This is a further reason

FIG. 3: Test of Proposal 2 for Wigner majorization in Result 8 (Sec. II C) through the difference (105) evaluated for a pair of Wigner functions  $W_1$  and  $W_2$ . Left:  $W_1 = W_{|0\rangle}$  and  $W_2 = W_{|1\rangle}$ , where  $W_{|n\rangle}$  is defined in (88). Right:  $W_1 = \widetilde{W}_{3/5}$  and  $W_2 = \widetilde{W}_{9/10}$ , where both the Wigner functions are defined in (89). In both panels, the curves are shown as functions of t for various values of  $\Lambda$ , exhibiting collapse for large  $\Lambda$ . In the left panel the asymptotic curve has no definite sign, implying the absence of majorization order between  $W_{|0\rangle}$  and  $W_{|1\rangle}$ , while in the right panel the asymptotic curve takes only negative values, meaning that  $W = \widetilde{W}_{9/10} \succ W = \widetilde{W}_{3/5}$ .

why, in the next sections, we mostly focus on Proposals 1 and 2.

#### B. Relations with logarithmic Wigner negativity

In this subsection, we show that whenever a Wigner majorization relation occurs between two states, the corresponding Wigner logarithmic negativities are related in the same way. This claim holds for the Wigner majorization order induced by any of the three proposals discussed in Sec. V A and summarized in Result 8.

Given a state  $\hat{\rho}$  with Wigner function  $W_{\hat{\rho}}$ , let us evaluate the functional (86) for t = 0 on  $W_{\hat{\rho}}$  and  $|W_{\hat{\rho}}|$ . From (39), we can rewrite both functionals in terms of the Wigner logarithmic negativity of  $\hat{\rho}$  as follows

$$I_0[|W_{\hat{\rho}}|] = e^{\mathcal{N}_{W_{\hat{\rho}}}}, \quad I_0[W_{\hat{\rho}}] = \frac{e^{\mathcal{N}_{W_{\hat{\rho}}}} + 1}{2}.$$
(108)

Crucially, both the functions of the Wigner logarithmic negativity in (108) are monotonically increasing. It is worth mentioning that the relations in (108) could be exploited to gain insights into the Wigner logarithmic negativity. For instance, combining the first relation with the behavior observed in the inset of the left panel of Fig. 2, we can argue that  $\mathcal{N}_{W|n\rangle} \sim \ln n$  for  $n \to \infty$ , where  $W_{|n\rangle}$ are the Wigner functions (88) of the harmonic oscillator eigenstates.

Now, consider two CV states  $\hat{\rho}_1$  and  $\hat{\rho}_2$  with Wigner functions  $W_1$  and  $W_2$  respectively. From Result 8,  $\hat{\rho}_1 \succ_w \hat{\rho}_2$  if either

$$I_t[|W_1|] - I_t[|W_2|] \ge 0, \quad \forall t \ge 0 \quad (\text{Proposal 1}), \quad (109)$$
  
or

$$I_t[W_1] - I_t[W_2] \ge 0, \quad \forall t \in \mathbb{R} \quad (\text{Proposal } 2).$$
(110)

Since (109) and (110) must hold also in the special case given by t = 0, by exploiting the monotonicity of the functions in (108), we have that  $\mathcal{N}_{W_1} \geq \mathcal{N}_{W_2}$  when  $\hat{\rho}_1 \succ_{W}$  $\hat{\rho}_2$ , according to Proposals 1 and 2. This proves Result 9 for Proposals 1 and 2 of generalized Wigner majorization.

In order to prove also Result 9 for Proposal 3, it is enough to recall that, when  $\hat{\rho}_1 \succ_W \hat{\rho}_2$ , there exists a Gaussian channel  $\mathcal{E}$  such that  $\mathcal{E}(\hat{\rho}_1) = \hat{\rho}_2$ . In [21, 22], the authors prove that, in CV systems, the Wigner logarithmic negativity is monotonic under a class of operations called Gaussian protocols, which include the Gaussian channels. This leads to the conclusion that  $\hat{\rho}_1 \succ_W \hat{\rho}_2$ implies  $\mathcal{N}_{W_1} \geq \mathcal{N}_{W_2}$  also if  $\succ_W$  is evaluated through Proposal 3. This concludes the proof of Result 9.

In the rest of this subsection, we focus on another family of quantities that can be constructed from the Wigner function of a given state, namely the Wigner Renyi entropies defined in (41). In [20], the Wigner Renyi entropies have been studied in DV systems defined on Hilbert spaces with odd dimensionality. For these quantities to be well-defined for states that are not Wignerpositive, one can choose  $\alpha = 2p/(2q-1)$ , with p and q integer numbers. With this choice, in [20] it has been proved that the Wigner Renyi entropies of an output state obtained from a positivity-preserving operation is always larger than the one of the corresponding input state. Motivated by this finding, in the following we try to establish a similar inequality between the Wigner Rényi entropies of CV states connected by Gaussian channels. To include all CV states in our analysis, hereafter we restrict the discussion to Wigner Rénvi with  $\alpha = 2p/(2q-1)$ . In the literature, we find other attempts to define a Wigner entropy for states whose Wigner function may admit negative values. For this purpose, in [52], a complex Wigner entropy has been introduced via an analytic continuation to a complex phase space.

Let us consider a CV state  $\hat{\rho}_{in}$  with Wigner function

FIG. 4: Left: The difference between  $S_W^{(\alpha)}$  evaluated on the output state obtained by applying a thermal noise channel (77) and the corresponding input state given by the mixture (89). The curves are plotted as functions of the parameter s of the thermal noise channel, with c = 0.75. Two different input states corresponding to two different values of u and three distinct values of the Rényi index  $\alpha = 2p/(2q-1)$ , with p and q integers, are considered. The fact that the curves have no definite sign shows that  $S_W^{(\alpha)}$  (and the Wigner Renyi entropy with even indices) are not in general monotonic under Gaussian channels. Right: The logarithm of the determinant of the matrix X characterizing the thermal noise channel is subtracted from the quantity plotted in the left panel. The curves confirm the inequality (113).

 $W_{\rm in}$  and, given a Gaussian channel  $\mathcal{E}$  identified by the matrices X and Y, let us define  $\hat{\rho}_{\rm out} = \mathcal{E}(\hat{\rho}_{\rm in})$  and  $W_{\rm out}$  its Wigner function. The Wigner functions  $W_{\rm in}$  and  $W_{\rm out}$  are related by (32). By using the triangular inequality, we can write the inequality

$$|W_{\text{out}}(\boldsymbol{r})| \leq \int d\boldsymbol{z} k(\boldsymbol{r}, \boldsymbol{z}) |W_{\text{in}}(\boldsymbol{z})|,$$
 (111)

where we have also exploited that k is a positive function. Now let  $\Phi$  be a non-negative increasing convex function  $\Phi : \mathbb{R}_+ \to \mathbb{R}_+$  such that  $\Phi(0) = 0$ . The following inequalities hold

$$\int d\boldsymbol{r} \, \Phi\left(\det X|W_{\text{out}}(\boldsymbol{r})|\right) \leq \\ \leq \int d\boldsymbol{r} \, \Phi\left(\int d\boldsymbol{z} \, \det Xk(\boldsymbol{r}, \boldsymbol{z})|W_{\text{in}}(\boldsymbol{z})|\right) \\ \leq \int d\boldsymbol{r} \int d\boldsymbol{z} \, \det Xk(\boldsymbol{r}, \boldsymbol{z})\Phi(|W_{\text{in}}(\boldsymbol{z})|) \\ = \int d\boldsymbol{z} \, \det X \int d\boldsymbol{r} \, k(\boldsymbol{r}, \boldsymbol{z})\Phi(|W_{\text{in}}(\boldsymbol{z})|) \\ = \int d\boldsymbol{z} \, \det X\Phi(|W_{\text{in}}(\boldsymbol{z})|) .$$
(112)

The first inequality follows from (111) and  $\Phi$  being nonnegative and increasing. The second inequality is implied by Jensen's inequality because, from (34), we have that det  $Xk(\mathbf{r}, \mathbf{z})$  is a probability distribution over  $\mathbf{z}$ . Finally, the last inequality comes from (34). The function  $\Phi(x) =$  $x^{\alpha}$  with  $\alpha \geq 1$  and  $x \in [0, \infty)$  satisfies all the assumptions and, therefore, by applying it to (112), yields Result 10. Taking the logarithm of the two sides of (42) and dividing by the negative quantity  $1 - \alpha$  (we assume  $\alpha = 2p/(2q 1) \geq 1$ ), we find

$$-\ln \det X + S_{W_{\text{out}}}^{(\alpha)} \ge S_{W_{\text{in}}}^{(\alpha)}, \qquad (113)$$

where  $S_W^{(\alpha)}$  is defined in (41).

For any value of  $\alpha = 2p/(2q-1)$ , (42) exhibits a dependence on the matrix X characterizing the Gaussian channel applied to the input state. This dependence does not allow to prove the monotonicity of  $S_W^{(\alpha)}$  under Gaussian channels, suggesting also that this monotonicity might not be valid in the CV case. This hand-wavy argument is verified by explicit counterexamples reported in Fig. 4. In the left panel of Fig. 4, we show the difference between  $S_{W_{\text{in}}}^{(\alpha)}$  with input state (89) and  $S_{W_{\text{out}}}^{(\alpha)}$ , where the output state is obtained by applying the thermal noise channel (77) to the input state. The results are plotted as functions of s parameter in (77) with a fixed value of the other parameter c = 0.75. We report the curves for two values of u, namely for two different input states, and for three values of the Rényi index  $\alpha = 2p/(2q-1)$ , with p and q integer. The lack of definite sign for the curves in this panel confirms that  $S_W^{(\alpha)}$  and the Rényi entropies with even index are not monotonic under Gaussian channels. To check the validity of the inequality (113), in the right panel we subtract  $\ln \det X = \ln(1-s)$  (see (77)) from the difference  $S_{W_{\text{out}}}^{(\alpha)} - S_{W_{\text{in}}}^{(\alpha)}$ . As expected, all the curves are positive in this panel. Thus, the analysis above and the results showed in Fig. 4 allows us to conclude that there is no monotonicity for the Wigner Rényi entropies (or any of their generalizations) under Gaussian channels.

According to the discussion above, the absence of monotonicity of the Wigner Rényi entropies highlights another difference from the perspective of Wigner majorization between CV systems and the DV systems on Hilbert spaces with odd dimensionality studied in [20]. Finally, we find it worth commenting that, setting  $\alpha = 1$ in (42), the dependence on X drops out and we obtain an alternative proof of the monotonicity of the Wigner logarithmic negativity under Gaussian channels, already

# C. Quantum channels on generic input Wigner functions

In this subsection, we exploit all the three Wigner majorizations proposed in Result 8 to investigate the relation between generic CV states and the output obtained by applying quantum operations. Similarly to the analysis in Sec. IV, we mainly focus on Gaussian channels.

#### 1. Gaussian channels

Let us begin by considering the action of Gaussian channels on generic CV states and studying possible Wigner majorization relations between input and output states. Among the three proposals in Result 8, Proposal 3 is the most straightforward to discuss in this respect. Indeed, as mentioned in Sec. VA3, this Wigner majorization relation is established, by construction, only between CV states related by a Gaussian channel. More precisely, every output state obtained by applying a Gaussian channel to a CV state is majorized by the corresponding input state. As discussed in Sec. IIC, Proposal 3 tautologically realizes a version of Nielsen's theorem for Wigner majorization and, therefore, could be of potential use in the context of the resource theory of non-Gaussianity and Wigner negativity. We postpone investigations along this line for future works.

The same analysis on Proposals 1 and 2 requires more effort. Since these two proposals reduce to the Wigner majorization introduced in [28] when evaluated for a pair of Wigner-positive states, we already know from Sec. IV A that there is not a fixed relation between the output state obtained from a Gaussian channel and the corresponding Wigner-positive input state. To show that this is the case also if the input state is not Wignerpositive, in Fig. 5, we show the results obtained for three different choices of single-mode input states (89) and thermal noise channels (77) applied to them. More precisely, we evaluate the functional  $I_t$  in (86) on the absolute value of the input Wigner functions  $W_{\rm in}$  (orange curves) and on the absolute value of the corresponding output Wigner functions  $W_{out}$  (blue curves) and we plot the outcomes against t. The values of the parameters uof the input state (89) and c and s of the channel (77) applied to it are reported in the panels. The explicit expressions of the output Wigner functions obtained after applying (77) to the single-mode mixed state (89) are reported for completeness in Appendix D. In the left panel, we report an example where  $|W_{out}| \gg |W_{in}|$  and, therefore,  $\hat{\rho}_{out} \succ_{W} \hat{\rho}_{in}$ . On the other hand, in the middle panel, considering a different input state and a different thermal noise channel, we have  $|W_{\text{in}}| \gg |W_{\text{out}}|$  and  $\hat{\rho}_{\text{in}} \succ_{\text{W}} \hat{\rho}_{\text{out}}$ . Finally, in the right panel, the two curves intersect, signaling the absence of Wigner majorization order between  $\hat{\rho}_{in}$ and  $\hat{\rho}_{out}$  This figure explicitly shows the absence of a fixed

Wigner majorization order through Proposal 1 between a generic input CV state and the output state obtained by applying a Gaussian channel. Analogous conclusions can be drawn for Proposal 2, although we do not report the results here for brevity.

To complement this finding, in the following we provide a criterion, valid in certain cases, to rule out the existence of a Gaussian channel connecting two CV states or the presence of a Wigner majorization order.

**Proposition 1** If there exists a Gaussian channel  $\mathcal{E}$  such that  $\mathcal{E}(\hat{\rho}_{in}) = \hat{\rho}_{out}$  where  $\hat{\rho}_{in}$  and  $\hat{\rho}_{out}$  have different Wigner logarithmic negativity, then  $\hat{\rho}_{out}$  cannot Wigner-majorize  $\hat{\rho}_{in}$  according to Proposals 1 and 2 in Result 8.

Proof: As shown in [21, 22] (see also Result 10 with  $\alpha = 1$ ), if  $\mathcal{E}(\hat{\rho}_{\rm in}) = \hat{\rho}_{\rm out}$ , then  $\mathcal{N}_{W_{\rm in}} > \mathcal{N}_{W_{\rm out}}$ , where  $W_{\rm in}$  and  $W_{\rm out}$  are the Wigner functions of the input state and the output state respectively and  $\mathcal{N}_W$  is defined in (39). Notice that the previous inequality is strict by hypothesis. If  $\hat{\rho}_{\rm out} \succ_W \hat{\rho}_{\rm in}$ , given the functional  $I_t$  defined in (86), we would have either

$$I_t[|W_{\text{out}}|] \ge I_t[|W_{\text{in}}|] \quad \forall t \ge 0, \qquad (114)$$

or

$$I_t[W_{\text{out}}] - I_t[W_{\text{in}}] \ge 0 \quad \forall t \in \mathbb{R}, \qquad (115)$$

for Proposal 1 and Proposal 2, respectively. In particular, we would have either  $I_0[|W_{out}|] \ge I_0[|W_{in}|]$ or  $I_0[W_{out}] - I_0[W_{in}] \ge 0$  for the two considered proposals. Using (108), these inequalities would imply  $\mathcal{N}_{in} \le \mathcal{N}_{out}$ , contradicting the hypotheses. Thus, the relation  $\hat{\rho}_{out} \succ_W \hat{\rho}_{in}$  is is ruled out, according to Proposal 1 or Proposal 2 in Result 8.

**Proposition 2** Given two CV states  $\hat{\rho}_1$  and  $\hat{\rho}_2$  with *different* Wigner logarithmic negativities and satisfying  $\hat{\rho}_1 \succ_w \hat{\rho}_2$ , a Gaussian channel such that  $\mathcal{E}(\hat{\rho}_2) = \hat{\rho}_1$  does not exist.

**Proof:** From the Proposals 1 or 2 in Result 8 and Result 9, if  $\hat{\rho}_1 \succ_W \hat{\rho}_2$ , we have that  $\mathcal{N}_{W_1} > \mathcal{N}_{W_2}$ , where  $W_1$  and  $W_2$  are the Wigner functions of  $\hat{\rho}_1$  and  $\hat{\rho}_2$  respectively and  $\mathcal{N}_W$  is defined in (39). Again, the inequality between the Wigner logarithmic negativities is strict by hypothesis. As shown in [21], the existence of a Gaussian channel  $\mathcal{E}$  such that  $\mathcal{E}(\hat{\rho}_2) = \hat{\rho}_1$  would imply  $\mathcal{N}_{W_1} \leq \mathcal{N}_{W_2}$ . This would contradict the hypotheses, thus ruling out the existence of the channel  $\mathcal{E}$ .

The two criteria reported above are not fully general due to the necessary assumptions on the Wigner negativities of the two states involved. We postpone refinement of these results towards a generalization with less stringent hypotheses to future works.

After this analysis on the Wigner majorization order between a generic CV state and the output state obtained by applying Gaussian channels, it is natural to

FIG. 5: Comparison of the functional defined in (86) evaluated on the absolute values of input single-mode Wigner functions (89) (orange) and of the corresponding output Wigner functions (blue) after the application of a thermal noise channel (77). The values of the parameters of the input state and the applied channel are reported in each panel. The panels show that input and output states do not have any fixed Wigner majorization relation according to Proposal 1 in Result 8. Wigner majorization can be observed depending on the choice of the parameters:  $\hat{\rho}_{out} \succ_W \hat{\rho}_{in}$  in the left panel,  $\hat{\rho}_{in} \succ_W \hat{\rho}_{out}$  in the middle panel, no Wigner majorization relation in the right panel.

ask whether the class of channels with det X = 1 introduced in Sec. IV B are Wigner-majorizing channels also when acting on generic CV states. This is the content of Result 11. For simplicity, we restrict our analysis to Proposal 1 in Result 8. Let us consider a generic CV state  $\hat{\rho}_{in}$  and act on it with a Gaussian channel  $\mathcal{E}$  characterized by the matrices X and Y. We denote the output state as  $\hat{\rho}_{out} = \mathcal{E}(\hat{\rho}_{in})$ . Let us call  $W_{in}$  and  $W_{out}$  the Wigner functions of input and output states, respectively. To prove Result 11, we want to show that if  $W_{in}$  and  $W_{out}$  are related by (32) with k bi-stochastic kernel, then  $W_{in}$  and  $W_{out}$  satisfy

$$\int [|W_{\text{out}}(\boldsymbol{r})| - t]_{+} d\boldsymbol{r} \leq \int [|W_{\text{in}}(\boldsymbol{r})| - t]_{+} d\boldsymbol{r}, \quad \forall t \ge 0,$$
(116)

namely  $\hat{\rho}_{\text{in}} \succ_{W} \hat{\rho}_{\text{out}}$  according to Proposal 1. This would be sufficient to prove Result 11, given that k in (33) is bi-stochastic if and only if det X = 1 (see (34)).

We begin by noticing that the functional  $[\cdot - t]_+$  is convex and monotonically increasing [25]. Given the condition

$$\int d\boldsymbol{z} k(\boldsymbol{r}, \boldsymbol{z}) = 1, \qquad (117)$$

since k is bistochastic, we can apply Jensen's inequality and write the following inequality

$$\int d\boldsymbol{r} \left[ \int d\boldsymbol{z} k(\boldsymbol{r}, \boldsymbol{z}) |W_{\text{in}}(\boldsymbol{z})| - t \right]_{+} \leq$$
(118)

$$\leq \int dm{r} dm{z} k(m{r},m{z})[|W_{ ext{in}}(m{z})|-t]_+ \leq \int dm{z}[|W_{ ext{in}}(m{z})|-t]_+$$

where, in the last step, we have used the other bistochastic condition in (34). From (111) and the fact that  $[\cdot -t]_+$ is monotonically increasing, we have

$$\int d\boldsymbol{r}[|W_{\text{out}}(\boldsymbol{r})| - t]_{+} \leq \int d\boldsymbol{r} \left[ \int d\boldsymbol{z} k(\boldsymbol{r}, \boldsymbol{z}) |W_{\text{in}}(\boldsymbol{z})| - t \right]_{+}$$
(119)

which, combined with (118), leads to (116). Thus, we can conclude that the Gaussian channels with det X = 1 are Wigner-majorizing when applied to a *generic* CV state, as stated in Result 11.

# 2. Beyond Gaussian channels

So far, in studying the interplay between Wigner majorization and quantum operations we have considered only Gaussian channels, i.e. channels that map Gaussian states into Gaussian states. To extend our analysis beyond this class of quantum channels, in this subsection, we consider the random unitary Gaussian channels defined in (45). These channels act on the input state by randomly applying Gaussian unitaries (associated to a symplectic transformation S) and displacements  $\bar{r}$  according to a given probability distribution  $p(S, \bar{r})$ . As discussed in Sec. II C, if the random operations acting on the input state amounts only to displacements, and, consequently, the probability distribution becomes  $p(S, \bar{r}) = p(\bar{r})$ , the resulting channel is called random displacement channel. Interestingly, if  $p(\bar{r})$  is a Gaussian distribution, we obtain a classical mixing channel, discussed in detail in Sec. IV B.

In this subsection, we aim to prove Result 12, which claims that any output state obtained from a general random unitary Gaussian channel (45) is Wigner majorized by the corresponding input state according to Proposal 1 in Result 8. Employing the usual notation, we consider an input state  $\hat{\rho}_{in}$  and its Wigner function  $W_{in}$ . We denote by  $\hat{\rho}_{out} = \mathcal{E}_p(\hat{\rho}_{in})$  the output state obtained by applying a random unitary Gaussian channel (45) with probability distribution p, and  $W_{out}$  its Wigner function. Since the channel (45) randomly implements Gaussian unitaries and displacements, its action on the input Wigner function can be written as

$$W_{\text{out}}(\boldsymbol{r}) = \int dS d\boldsymbol{\bar{r}} \ p\left(S, \boldsymbol{\bar{r}}\right) W_{\text{in}}(S\boldsymbol{r} + \boldsymbol{\bar{r}}) \,. \tag{120}$$

Notice that the integral over S is performed over the Haar measure on the group of symplectic transformations. Now consider a generic convex non-increasing function  $\Phi : \mathbb{R}_+ \to \mathbb{R}_+$  such that  $\Phi(0) = 0$ . Using (120), the triangular inequality and the non-increasing property of  $\Phi$ , we obtain

$$\int d\boldsymbol{r} \, \Phi(|W_{\text{out}}(\boldsymbol{r})|) \qquad (121)$$

$$= \int d\boldsymbol{r} \, \Phi\left(\left|\int dS d\bar{\boldsymbol{r}} \, p\left(S, \bar{\boldsymbol{r}}\right) W_{\text{in}}(S\boldsymbol{r} + \bar{\boldsymbol{r}})\right|\right)$$

$$\leq \int d\boldsymbol{r} \, \Phi\left(\int dS d\bar{\boldsymbol{r}} \, p\left(S, \bar{\boldsymbol{r}}\right) |W_{\text{in}}(S\boldsymbol{r} + \bar{\boldsymbol{r}})|\right),$$

where we have further exploited that the probability distribution p is positive. Since  $\Phi$  is also convex, we can apply Jensen's inequality to (121), finding

$$\int d\boldsymbol{r} \, \Phi(|W_{\text{out}}(\boldsymbol{r})|) \qquad (122)$$

$$\leq \int d\boldsymbol{r} \int dS \, d\bar{\boldsymbol{r}} \, p\left(S, \bar{\boldsymbol{r}}\right) \Phi(|W_{\text{in}}(S\boldsymbol{r}+\bar{\boldsymbol{r}})|)$$

$$= \int dS \, d\bar{\boldsymbol{r}} \, p\left(S, \bar{\boldsymbol{r}}\right) \int d\boldsymbol{r} \, \Phi(|W_{\text{in}}(\boldsymbol{r})|) \,,$$

where in the last step we have performed the change of variables  $S\mathbf{r} + \bar{\mathbf{r}} \to \mathbf{r}$ , which does not alter the integration measure over  $\mathbf{r}$ . Finally, using the normalization of  $p(S, \bar{\mathbf{r}})$ , we obtain

$$\int d\boldsymbol{r} \, \Phi(|W_{\text{out}}(\boldsymbol{r})|) \leq \int d\boldsymbol{r} \, \Phi(|W_{\text{in}}(\boldsymbol{r})|) \,. \tag{123}$$

Given that (123) holds for any non-increasing convex positive function  $\Phi$  which is vanishing in zero, using the condition 2 in Sec. II A (see (6)), we have that  $|W_{\text{in}}(\boldsymbol{r})| \gg$  $|W_{\text{out}}(\boldsymbol{r})|$ . By definition of Proposal 1 in Result 8, this implies  $\hat{\rho}_{\text{in}} \succ_{\text{w}} \hat{\rho}_{\text{out}}$ , which proves Result 12.

Result 12 has insightful connections with Uhlmann's theorem. Recalling that an unital channel is a quantum channel that maps the identity into itself, Uhlmann's theorem states that the output state of any unital channel is density matrix-majorized (see Sec. II A) by the corresponding input state. According to the definition, the channel (45) is unital. This fact can be shown by exploiting the normalization of the probability distribution p. Thus, Result 12 could be seen as a realization of an analog of Uhlmann's theorem for Wigner majorization between CV states. Extending this result to understand the Wigner majorization relation between CV states and the output state after applying a generic unital channel is a task that deserves future investigations.

# VI. DISCUSSION AND OUTLOOK

In this work we have developed the theory of continuous majorization of Wigner functions in quantum phase space, or Wigner majorization in short. We have extended previous work [28] to the general *N*-mode case, both to Wigner-positive states and states with finite nonvanishing Wigner negativity. We have also investigated majorization between input and output states of Gaussian channels, and some more general channels.

For Gaussian states, we found a simple criterion for majorization, which is equivalent to comparing the purity of the states. Consequently, there is always a Wigner majorization relation between a pair of Gaussian states, but it does not add any qualitatively new information beyond purity. Moreover, for Gaussian channels, the Wigner majorization relation between input and output states can work both ways, as we demonstrated with the simple thermal channel example. This situation is also in contrast with the DV case: the counterpart majorization relation between discrete Wigner functions of input and output states is always one-way (input majorizes the output) under stabilizer operations, the counterpart of Gaussian operations. In the CV case, we also gave a partial proof of the conjecture made in [28]: we showed (Result 2) that in the convex hull of N-mode Gaussian states the equivalence class of pure Gaussian states Wigner majorizes all other states. This is expected, given the relation between majorization and purity. One potentially useful result is the rewriting of the Gaussian channel map from input Wigner function of a to output Wigner function [37] as a convolution with a kernel associated to the channel (Result 6). This kernel is well-defined, as opposed to one computed using the Choi-Jamiolkowski dual representation (80).

When we extend the definition of Wigner majorization to include Wigner-negative states with finite Wigner negativity, in addition to Wigner-positive states, more features begin to appear. First of all, in Result 8 we proposed three different definitions for Wigner majorization of generic states. Proposal 2 was modeled as the direct counterpart of Wigner majorization in the DV case, but requires careful regularization procedures. This is why we focused on a more detailed study of Proposal 1. Both proposals have the desired feature of implying monotonicity of Wigner logarithmic negativity (Result 9). However, from the point of view of resource theories of Wigner negativity or non-Gaussianity, both proposals fail to work as a natural preorder (since under Gaussian channels, we do not have a one-way relation of input always majorizing the output). For this reason we also included Proposal 3, where we just declare that Wigner majorization is equivalent to finding a Gaussian channel between the two states: this by definition mimics the situation in the DV case, and is the reason why we called it as "tautological" majorization. It would be insightful to find other equivalent definitions. For instance, since, as discussed at the end of Sec. VA3, Proposal 3 does not satisfy (11), it would be interesting to improve the Wigner majorization proposal in such a way it fulfills this property. A promising way is suggested by (107): this extension requires including probabilistic combinations of Gaussian channels, characterized by a kernel that is a convex combination of kernels (33), as Wigner-majorizing channels.

Wigner majorization by Proposals 1 or 2 are natural concepts, and characterize the "randomness" of Wigner functions. A question for further study is to find interesting applications in some CV settings, and also investigate if the two definitions are in fact equivalent. (We found that to be true in some test cases, but did not pursue the question further to report any progress here). We also identified a subclass of Gaussian channels where the input always majorizes the output (Result 11), and proved that the same is true for a class of non-Gaussian channels: the random Gaussian unitary channels (Result 12). Perhaps there is some interesting resource theory where such operations are considered free, and Wigner majorization is the natural preorder.

Our initial motivation for this work came from the question what natural notions of majorization could exist in quantum field theories. Continuous majorization of Wigner functions is one such natural concept, defined from first principles, that can be applied to any perturbative quantum field theory where the notion of a Fock space is a starting point. What other natural notions could exist, and what applications could be found? For example, recent work has investigated Wigner functions in Krylov space as a measure of the growth of complexity in chaotic dynamics [53]. One possible direction could be to explore whether Wigner majorization is well suited to characterize the growth of chaos and complexity.

#### Appendix A: Transformations of Wigner functions through Gaussian channels

For completeness, in this appendix, we derive the formula (32) in the main text, which was originally found in [54, 55].

The first ingredient we exploit is that the characteristic function  $\chi_{out}$  of an output state of a Gaussian channel  $\mathcal{E}$  is related to the one of the input state  $\chi_{in}$  as [1]

$$\chi_{\rm out}(\boldsymbol{r}) = e^{-\frac{1}{2}\boldsymbol{r}^{\rm t}J^{\rm t}YJ\boldsymbol{r}}\chi_{\rm in}(J^{\rm t}X^{\rm t}J\boldsymbol{r})\,,\qquad({\rm A1})$$

where X and Y are the matrices characterizing the Gaussian channel according to (31). Notice the different factor 1/2 instead of 1/4 in the exponent of (A1), compared with the corresponding formula in [1]. This is due to the

different definition of the covariance matrix, which (in Williamson's basis) is  $\frac{1}{2}\mathbf{1}$  in our conventions and  $\mathbf{1}$  in the convention of [1]. The Wigner function of a state is related to its characteristic function by (18). To avoid carrying the parameter N throughout the computation, we restrict the analysis to the single-mode case, i.e. N = 1, stressing that for N > 1, the calculation is identical. Combining (A1) and (18), we find the relation between the Wigner function of the output state and the characteristic function of the input state. It reads

$$W_{\text{out}}(\boldsymbol{r}) = \frac{1}{4\pi^2} \int d\boldsymbol{r}' e^{i\boldsymbol{r}'J\boldsymbol{r}} e^{-\frac{1}{2}\boldsymbol{r}'^{\text{t}}J^{\text{t}}YJ\boldsymbol{r}'} \chi_{\text{in}}(J^{\text{t}}X^{\text{t}}J\boldsymbol{r}') \,.$$
(A2)

We want to prove (32) with N = 1 by showing that it is the same as (A2). We begin by plugging (18) connecting  $W_{\rm in}$  and  $\chi_{\rm in}$  into (32) and we obtain

$$W_{\text{out}}(\boldsymbol{r}) = \int d\boldsymbol{w} d\boldsymbol{v} \chi_{\text{in}}(\boldsymbol{v}) e^{\mathbf{i}\boldsymbol{v}^{\text{t}}J\boldsymbol{w}} \frac{e^{-\frac{1}{2}(\boldsymbol{r}-\boldsymbol{X}\boldsymbol{w})^{\text{t}}\boldsymbol{Y}^{-1}(\boldsymbol{r}-\boldsymbol{X}\boldsymbol{w})}}{8\pi^{3}\sqrt{\det\boldsymbol{Y}}}.$$
(A3)

The integral over  $\boldsymbol{w}$  is Gaussian and can be performed, yielding

$$\int d\boldsymbol{w} e^{\left(\mathbf{i}\boldsymbol{v}^{\mathrm{t}}J+\boldsymbol{r}^{\mathrm{t}}Y^{-1}X\right)\boldsymbol{w}} e^{-\frac{1}{2}\boldsymbol{w}^{\mathrm{t}}X^{\mathrm{t}}Y^{-1}X\boldsymbol{w}} =$$
(A4)
$$= 2\pi \frac{\sqrt{\det Y}}{\det X} e^{\frac{1}{2}\boldsymbol{r}^{\mathrm{t}}Y^{-1}\boldsymbol{r}} e^{-\frac{1}{2}\boldsymbol{v}^{\mathrm{t}}JX^{-1}YX^{-\mathrm{t}}J^{\mathrm{t}}\boldsymbol{v}} e^{\mathbf{i}\boldsymbol{v}^{\mathrm{t}}JX^{-1}\boldsymbol{r}},$$

where we have also used the fact that the matrix Y is symmetric and so is its inverse. Plugging (A4) into (A3), we find

$$W_{\text{out}}(\boldsymbol{r}) = \int \frac{d\boldsymbol{v}}{4\pi^2} \frac{\chi_{\text{in}}(\boldsymbol{v})}{\det X} e^{-\frac{1}{2}\boldsymbol{v}^{\text{t}}JX^{-1}YX^{-\text{t}}J^{\text{t}}\boldsymbol{v}} e^{i\boldsymbol{v}^{\text{t}}JX^{-1}\boldsymbol{r}},$$
(A5)

which leads to (A2) once we perform the change of variables  $\mathbf{r'} = JX^{-t}J^t\mathbf{v}$ , with  $d\mathbf{r'} = \frac{d\mathbf{v}}{\det X}$ . Thus, we have proven (32) for N = 1. Notice that the derivation for generic N follows the same steps.

# Appendix B: Choi–Jamiolkowski isomorphism for Gaussian operations

In this appendix, we review the basics of the C-J isomorphism and how it is implemented for CV systems. The C-J isomorphism is a bijective mapping between quantum completely positive maps describing quantum operations and quantum states. Let us first review its realization in the context of quantum systems defined on finite-dimensional Hilbert space. The basic idea is to double the Hilbert spaces where a quantum operation  $\mathcal{E}$  acts and apply the resulting operation to a maximally entangled state defined on the doubled Hilbert space. Thus, if  $\mathcal{E}$  acts on  $\mathcal{H}$ , the density matrix  $\hat{\rho}_C$  of the state resulting from the C-J isomorphism, also called Choi state, belongs to  $\mathcal{H}^{\otimes 2}$ . Formally, the Choi state reads [35, 36, 56]

$$\hat{\rho}_C = (\mathcal{E} \otimes \mathbf{1}_{\mathcal{H}})(|\psi\rangle\langle\psi|), \qquad (B1)$$

where  $|\psi\rangle\langle\psi|$  is the state which maximally entangles the two copies of  $\mathcal{H}$ . Crucially, if  $\mathcal{E}$  is a completely positive operation, the density matrix  $\hat{\rho}_C$  is positive. In addition, if  $\mathcal{E}$  is also trace-preserving,  $\hat{\rho}_C$  has trace equal to one.

In infinite-dimensional Hilbert spaces, such as the ones where CV states are defined, the maximally entangled state is not normalizable, and the mapping (B1) has to be adapted. We first notice that in *N*-mode CV systems the maximally entangled state can be approximated by a limiting sequence of states  $|\psi_{\nu}\rangle^{\otimes N}$ , as  $\nu \to \infty$ . The states  $|\psi_{\nu}\rangle$  are defined as [1]

$$|\psi_{\nu}\rangle = \frac{1}{\cosh\nu} \sum_{j} (\tanh\nu)^{j} |j\rangle \otimes |j\rangle,$$
 (B2)

where  $|j\rangle$  is the Fock state obtained by applying j times the bosonic creation operator on the vacuum. In this context, the parameter  $\nu$  can be seen as a regulator for the maximally entangled state. At this point, the Choi reduced density matrix associated with a certain CV quantum operation  $\mathcal{E}$  can be seen as the limit for  $\nu \to \infty$  of the sequence of density matrices obtained as

$$\hat{\rho}_{C,\nu} = (\mathcal{E} \otimes \mathbf{1}_{\mathcal{H}}) \left( |\psi_{\nu}\rangle^{\otimes N} \langle \psi_{\nu}|^{\otimes N} \right) .$$
 (B3)

Given the expression of  $\hat{\rho}_{C,\nu}$ , one can compute the corresponding Wigner function for any value of  $\nu$  using (16) and (18) and finally evaluate it in the regime  $\nu \to \infty$ . The result can be interpreted as the Wigner function associated with the quantum operation  $\mathcal{E}$ .

When the operation  $\mathcal{E}$  is a Gaussian channel, the resulting Choi state is a Gaussian state, and the corresponding Wigner function is Gaussian [1]. This Gaussian distribution is supported on a quantum phase space parameterized by 4N coordinates, accounting for the doubling of the Hilbert space where the Choi state is defined. The expression of the Gaussian Wigner function is reported in (80), and it shows the dependence of the covariance matrix in the doubled phase space as a function of the matrices X and Y characterizing the Gaussian channel  $\mathcal{E}$ .

#### Appendix C: Tautological majorization and preorder

In this appendix, we prove that the tautological majorization introduced in Proposal 3 of Result 8 deserves the name of majorization relation. More precisely, we show that the relation  $\succ_t$  identifies a preorder. To verify this statement, we show that the following conditions hold.

1. For any Wigner function W

$$W \succ_{\mathrm{t}} W, \quad \forall W;$$
 (C1)

2. Given three generic Wigner functions  $W_1$ ,  $W_2$  and  $W_3$ 

if 
$$W_1 \succ_{\mathrm{t}} W_2, W_2 \succ_{\mathrm{t}} W_3, \Rightarrow W_1 \succ_{\mathrm{t}} W_3.$$
 (C2)

To check the validity of (C1) we observe that, taking the limit  $Y \to 0, X \to \mathbf{1}$  of the first expression in (38) with k defined in (33), we obtain

$$W_2(\boldsymbol{r}) = \int d\boldsymbol{y} \delta(\boldsymbol{r} - \boldsymbol{y}) W_1(\boldsymbol{y}) = W_1(\boldsymbol{r}). \quad (C3)$$

In other words, the kernel k reduces to the identity kernel ( $\delta$ -function), and, therefore, we can always find the tautological majorization between a Wigner function and itself. This fact is physically understood since the identity channel is a Gaussian channel. The second condition (C2) can be verified as follows. Given three Wigner functions  $W_1, W_2$  and  $W_3$ , the left side of (C2) can be rewritten as

$$W_1 \succ_{\mathrm{t}} W_2 \quad \Rightarrow \quad W_2(\boldsymbol{r}) = \int d\boldsymbol{z} k_{21}(\boldsymbol{r}, \boldsymbol{z}) W_1(\boldsymbol{z}) \,, \quad (\mathrm{C4})$$

and

$$W_2 \succ_{\mathrm{t}} W_3 \quad \Rightarrow \quad W_3(\boldsymbol{r}) = \int d\boldsymbol{z} k_{32}(\boldsymbol{r}, \boldsymbol{z}) W_2(\boldsymbol{z}) \,, \quad (\mathrm{C5})$$

where the kernels  $k_{ij}$  are given by (79) with matrices  $X_{ij}$ and  $Y_{ij}$  characterizing them. Thus, we have

$$W_{3}(\boldsymbol{r}) = \int d\boldsymbol{z} d\boldsymbol{y} k_{32}(\boldsymbol{r}, \boldsymbol{z}) k_{21}(\boldsymbol{z}, \boldsymbol{y}) W_{1}(\boldsymbol{y})$$
  
= 
$$\int d\boldsymbol{y} K(\boldsymbol{r}, \boldsymbol{y}) W_{1}(\boldsymbol{y}), \qquad (C6)$$

where the kernel K is given by (79) with the following X and Y

$$X = X_{32}X_{21}, \qquad Y = Y_{32} + X_{32}Y_{21}X_{32}^{t}.$$
 (C7)

This implies that  $W_1 \succ_t W_3$ . From the physical point of view, the validity of the condition (C2) comes from the fact that, by combining two Gaussian channels, we still obtain a Gaussian channel (the Gaussian channels form a semigroup [51]). We conclude that  $\succ_t$  is a preorder, and we can refer to it as tautological majorization order.

One might wonder whether  $\succ_t$  is also a partial order, meaning that, given any pair of Wigner functions  $W_1$  and  $W_2$ , the additional condition

if 
$$W_1 \succ_t W_2, \ W_2 \succ_t W_1, \quad \Rightarrow \quad W_1 = W_2, \quad (C8)$$

has to be fulfilled. This property is not true for  $\succ_t$ . Indeed, in the case of  $Y \rightarrow 0$ , namely when the Gaussian channel connecting  $W_1$  and  $W_2$  is a Gaussian unitary channel, we have that

$$W_2(\mathbf{y}) = W_1(X^{-1}\mathbf{y}),$$
 (C9)

where X is a symplectic matrix. The inverse transformation is, in this instance, well-defined and reads

$$W_2(X\boldsymbol{y}) = W_1(\boldsymbol{y}), \qquad (C10)$$

which implies that  $W_1 \succ_t W_2$  and  $W_2 \succ_t W_1$ , even if  $W_1 \neq W_2$ . Thus,  $\succ_t$  is not a partial order.

# Appendix D: Examples of Wigner functions after Gaussian channels

In this appendix, we report the analytical expressions of the Wigner functions of output states obtained by acting with thermal noise channels and classical mixing channels on the classes of single-mode CV states relevant to this manuscript.

#### 1. Thermal noise channels and oscillator eigenstates

We begin by considering the single-mode input state  $\hat{\rho}_{in} = (1-u)|0\rangle\langle 0| + u|1\rangle\langle 1|, u \in [0, 1]$ , where  $|0\rangle$  and  $|1\rangle$  are the vacuum and the first excited state of a harmonic oscillator respectively. The Wigner function  $\widetilde{W}_u$  of this state is reported in (89). We want to compute the Wigner function  $W_{out}$  of the output state obtained by applying to  $\hat{\rho}_{in}$  the thermal noise channel defined by the matrices X and Y in (77). The strategy is to exploit (32) evaluated on  $\widetilde{W}_u$  with the kernel k written in terms of the matrices (77).

Writing  $W_u$  in (89) explicitly in terms of the Laguerre polynomial of order zero and one, it turns out that the following integrals are useful for writing down the final result  $W_{\text{out}}$ 

$$\int dx' dp' e^{-\frac{(x-x')^2}{1-s} - \frac{(p-p')^2}{1-s}} e^{-\frac{1}{2cs}(x'^2 + p'^2)}$$
$$= \frac{2\pi cs(1-s)}{1+s(2c-1)} e^{-\frac{r^2}{1+s(2c-1)}},$$
(D1)

$$\int dx' dp' \frac{(x-x')^2}{1-s} e^{-\frac{(x-x')^2}{1-s} - \frac{(p-p')^2}{1-s}} e^{-\frac{x'^2+p'^2}{2cs}}$$
(D2)

$$= 2\pi cs(1-s)\frac{x^2(1-s)+cs[1+s(2c-1)]}{[1+s(2c-1)]^3}e^{-\frac{r^2}{1+s(2c-1)}}$$

and

=

$$\int dx' dp' \frac{(p-p')^2}{1-s} e^{-\frac{(x-x')^2}{1-s} - \frac{(p-p')^2}{1-s}} e^{-\frac{x'^2+p'^2}{2cs}}$$
(D3)  
=  $2\pi cs(1-s) \frac{p^2(1-s) + cs[1+s(2c-1)]}{[1+s(2c-1)]^3} e^{-\frac{r^2}{1+s(2c-1)}},$ 

where we have expressed the outcome in terms of the radial phase-space coordinate  $r = \sqrt{x^2 + p^2}$  whenever possible. Combining these three integrals, the Wigner function of the output state reads

$$W_{\text{out}}(x,p) = W_{\text{out}}(r) = e^{-\frac{r^2}{1+s(2c-1)}} \times$$
(D4)  
  $\times \frac{[1+s(2c-1)]^2 + 2u(1-s)[r^2 - 1 - s(2c-1)]}{\pi [1+s(2c-1)]^3}.$ 

Let us discuss the result (D4) in two significant regimes. When s = 0, we have

$$W_{\text{out}}(r) = e^{-r^2} \frac{1 + 2u(r^2 - 1)}{\pi} = \widetilde{W}_u(r),$$
 (D5)

which is consistent with the interpretation that, at s = 0, the thermal noise channel leaves the input state invariant. On the other hand, when s = 1, the thermal channel should transform the input state into a thermal state with eigenvalue c with probability equal to one. Indeed, the resulting Wigner function reads

$$W_{\rm out}(r) = \frac{e^{-\frac{r^2}{2c}}}{2\pi c}$$
 (D6)

Finally, if u = 0, we are mixing a thermal state with eigenvalue c and the vacuum state of the harmonic oscillator with probabilities s and 1 - s, respectively. Since both the states involved in this mixture are Gaussian, from the rule (31), we expect the output to be a Gaussian state with covariance matrix given by

$$\gamma_{\text{out}} = \frac{1-s}{2} + sc = \frac{1+s(2c-1)}{2}$$
. (D7)

By imposing u = 0 in (D4), we consistently find the Wigner function of the output state to be

$$W_{\rm out}(r) = \frac{e^{-\frac{r^2}{1+s(2c-1)}}}{\pi[1+s(2c-1)]} \,. \tag{D8}$$

The only parameter not defined on a finite domain is  $c \ge 1/2$ . It is worth noticing that when c is large enough, the output Wigner function can be approximated by

$$W_{\rm out}(r) \sim \frac{e^{-\frac{r^2}{2sc}}}{2\pi sc}$$
 when  $c \gg 1$ , (D9)

namely, the output state becomes Wigner-positive for large values of c.

For completeness, we can repeat this analysis for an input state given by another mixture of oscillator eigenstates, namely  $\hat{\rho}_{\rm in} = (1-u)|1\rangle\langle 1|+u|2\rangle\langle 2|$ , with  $u \in [0,1]$ . The Wigner state of this input state reads

$$W_{\rm in}(r) = (1-u)W_{|1\rangle}(r) + uW_{|2\rangle}(r),$$
 (D10)

where  $W_{|1\rangle}$  and  $W_{|2\rangle}$  are given in (88). Also in this case, we want to apply (32) to the input Wigner function (D10) with the kernel k determined by the matices (77). To simplify the computation, we can exploit the fact that the effect of the thermal noise channel applied to  $W_{|1\rangle}$ has been computed before in this section (see (D1)-(D3)). Thus, the Wigner function  $W_{out}$  of the resulting output state can be written as

$$W_{\text{out}}(x,p) = (1-u) \times$$
(D11)  
  $\times \frac{e^{-\frac{r^2}{1+s(2c-1)}}}{\pi} \frac{s(2+s(4c^2-1))-1+2r^2(1-s)}{[1+s(2c-1)]^3}$   
  $+ u \int dx' dp' W_{|2\rangle} \left(\frac{x-x'}{\sqrt{1-s}}, \frac{p-p'}{\sqrt{1-s}}\right) \frac{e^{-\frac{x'^2+p'^2}{2cs}}}{cs(1-s)2\pi}.$ 

By employing (88), we can write explicitly

The second term of (D11) can be computed by using the integrals (D1)-(D3) and the following relations (

$$W_{|2\rangle}\left(\frac{x-x'}{\sqrt{1-s}},\frac{p-p'}{\sqrt{1-s}}\right) =$$
(D12)  
=  $\frac{4e^{-\frac{(q-q')^2}{1-s}-\frac{(p-p')^2}{1-s}}}{\pi}\left[\frac{1}{4} - \frac{(x-x')^2 + (p-p')^2}{1-s} + \frac{\left((x-x')^2 + (p-p')^2\right)^2}{2(1-s)^2}\right].$ 

$$\frac{1}{\pi^2 cs(1-s)} \int dx' dp' \frac{(x-x')^4}{(1-s)^2} e^{-\frac{(x-x')^2}{1-s} - \frac{(p-p')^2}{1-s}} e^{-\frac{1}{2cs}(x'^2+p'^2)} = \\ = \frac{2e^{-\frac{r^2}{1+s(2c-1)}}}{\pi} \frac{x^4(1-s)^2 + 6cs(1-s)(1+s(2c-1))x^2 + 3c^2s^2[1+s(2c-1)]^2}{[1+s(2c-1)]^5},$$
(D13)

$$\frac{1}{\pi^2 cs(1-s)} \int dx' dp' \frac{(p-p')^4}{(1-s)^2} e^{-\frac{(x-x')^2}{1-s} - \frac{(p-p')^2}{1-s}} e^{-\frac{1}{2cs}(x'^2+p'^2)} = \frac{2e^{-\frac{r^2}{1+s(2c-1)}}}{\pi} \frac{p^4(1-s)^2 + 6cs(1-s)(1+s(2c-1))p^2 + 3c^2s^2[1+s(2c-1)]^2}{[1+s(2c-1)]^5}, \quad (D14)$$

$$\frac{2}{\pi^2 cs(1-s)} \int dx' dp' \frac{(x-x')^2 (p-p')^2}{(1-s)^2} e^{-\frac{(x-x')^2}{1-s} - \frac{(p-p')^2}{1-s}} e^{-\frac{1}{2cs}(x'^2+p'^2)} = \frac{4e^{-\frac{r^2}{1+s(2c-1)}}}{\pi} \frac{(x^2(1-s) + cs[1+s(2c-1)]) (p^2(1-s) + cs[1+s(2c-1)])}{[1+s(2c-1)]^5}.$$
 (D15)

Plugging the result back into (D11), through a bit of algebra, we obtain

$$W_{\text{out}}(r) = \frac{e^{-\frac{r^2}{1+s(2c-1)}}}{\pi [1+s(2c-1)]^5} \times$$
(D16)  
$$\left\{ (s+2cs-1)(1+(2c-1)s)^2 \times \\ \times (1-2u+s(2c+2u-1)) + \\ + 2r^2(1-s)(1+(2c-1)s) \times \\ \times (1-3u+s(3u+2c(1+u)-1)) + 2ur^4(1-s)^2 \right\}.$$

As expected, the Wigner function (D16) of the output state is normalized to one and is such that, when s = 0, the input Wigner function (D10) is retrieved, while, when s = 1, we obtain (D6).

#### 2. Thermal noise channels and cat states

Other prototypical examples of bosonic states with non-vanishing Wigner logarithmic negativity are the *cat states*. The pure states in this class are defined by the superposition of two coherent states as follows

$$|\operatorname{cat}_{\pm}(\boldsymbol{\alpha})\rangle = \frac{|\boldsymbol{\alpha}\rangle \pm |-\boldsymbol{\alpha}\rangle}{\sqrt{2(1 \pm e^{-|\boldsymbol{\alpha}|^2})}},$$
 (D17)

where the coherent state  $|\alpha\rangle$  is a pure Gaussian state whose Wigner function is given by (21) with  $\gamma = \frac{1}{2}$  and  $\bar{r} = \alpha$  and the vector  $\alpha \in \mathbb{R}^{2N}$  is called *size of the cat*. The Wigner functions of these two states are known and read [50]

$$W_{\pm}^{(\alpha)}(\mathbf{r}) = \frac{e^{-|\alpha + \mathbf{r}|^2} + e^{-|\alpha - \mathbf{r}|^2} \pm 2\cos(2\alpha \cdot \mathbf{r}) e^{-|\mathbf{r}|^2}}{2\pi \left(1 \pm e^{-|\alpha|^2}\right)}.$$
(D18)

Notice that, as expected, setting  $\alpha = 0$  in (D18), we retrieve the Wigner function of the ground state, i.e.

$$W_0(\mathbf{r}) = \frac{e^{-|\mathbf{r}|^2}}{\pi}$$
. (D19)

The goal of this subsection is to compute the Wigner function of the output state obtained by applying a thermal noise channel (77) to the single-mode cat state given by (D18) with N = 1.

For this purpose, the Wigner functions (D18) can be plugged into (32) with the kernel k in (33) defined in terms of the matrices (77). Performing some Gaussian integrals and manipulating the resulting expression, the Wigner function of the output state reads

$$W_{\pm,\text{out}}^{(\boldsymbol{\alpha})}(\boldsymbol{r}) = \frac{e^{-\frac{|\sqrt{1-s}\boldsymbol{\alpha}+\boldsymbol{r}|^2}{1+(2c-1)s}} + e^{-\frac{|\sqrt{1-s}\boldsymbol{\alpha}-\boldsymbol{r}|^2}{1+(2c-1)s}}}{2\pi \left(1 \pm e^{-|\boldsymbol{\alpha}|^2}\right) \left(1 + (2c-1)s\right)} \text{ (D20)}$$
  
$$\pm \frac{2\cos\left(\frac{2\sqrt{1-s}\boldsymbol{\alpha}\cdot\boldsymbol{r}}{1+(2c-1)s}\right) e^{-\frac{|\boldsymbol{r}|^2+2cs|\boldsymbol{\alpha}|^2}{1+(2c-1)s}}}{2\pi \left(1 \pm e^{-|\boldsymbol{\alpha}|^2}\right) \left(1 + (2c-1)s\right)}.$$

Let us comment on some consistency checks for the formula (D20). When s = 0,  $W_{\pm,out}^{(\alpha)}(\mathbf{r}) = W_{\pm}^{(\alpha)}(\mathbf{r})$ , namely we retrieve the input state Wigner function. On the other hand, when s = 1,  $W_{\pm,o}^{(\alpha)}(\mathbf{r})$  becomes the Wigner function (D6) of a thermal state with eigenvalue c. Finally, when  $\alpha = 0$ , we obtain the result of the application of a thermal noise channel to the ground state whose Wigner function is reported in (D8).

#### 3. Classical mixing channels

To conclude this appendix, we report the analytical expressions of the Wigner functions of the output states obtained by applying an example of classical mixing channel to the mixed states  $(1 - u)|0\rangle\langle 0| + u|1\rangle\langle 1|$  and  $(1-u)|1\rangle\langle 1|+u|2\rangle\langle 2|$ , with  $u \in [0, 1]$ , and to the cat states (D17).

Given a generic input state with Wigner function  $W_{in}$ , we first plug  $X = \mathbf{1}$  into (32) and, after the change of variable  $\mathbf{z} \to \mathbf{r} - \mathbf{y}$ , we obtain

$$W_{\text{out}}(\boldsymbol{r}) = \int d\boldsymbol{y} W_{\text{in}}(\boldsymbol{r} - \boldsymbol{y}) \frac{e^{-\frac{1}{2}\boldsymbol{y}^{\text{t}}Y^{-1}\boldsymbol{y}}}{(2\pi)^{N}\sqrt{\det Y}}, \qquad (\text{D21})$$

namely, the Wigner function of the output state is the convolution between the Wigner function of the input state and a Gaussian distribution with a covariance matrix given by Y.

Since we want to apply these channels to single-mode input states, we restrict our analysis to phase spaces with N = 1. For simplicity, we also consider the subclass of classical mixing channels with  $Y = c\mathbf{1}_2$ , c > 0 and  $\mathbf{1}_2$ being the  $2 \times 2$  identity matrix. To apply this classical mixing channel to the mixtures of oscillator eigenstates mentioned above, it is useful first to compute the following integrals

$$\int d\boldsymbol{y} W_{|0\rangle}(\boldsymbol{r} - \boldsymbol{y}) \frac{e^{-\frac{1}{2c}\boldsymbol{y}^{t}\boldsymbol{y}}}{2\pi c} = \frac{e^{-\frac{r^{2}}{1+2c}}}{\pi(1+2c)}, \qquad (D22)$$

$$\int d\boldsymbol{y} W_{|1\rangle}(\boldsymbol{r} - \boldsymbol{y}) \frac{e^{-\frac{1}{2c}\boldsymbol{y}^{t}\boldsymbol{y}}}{2\pi c} = \frac{e^{-\frac{r^{2}}{1+2c}}}{\pi (1+2c)^{3}} \left(2r^{2} + 4c^{2} - 1\right),$$
(D23)

$$\int d\boldsymbol{y} W_{|2\rangle}(\boldsymbol{r}-\boldsymbol{y}) \frac{e^{-\frac{1}{2c}\boldsymbol{y}^{\mathrm{t}}\boldsymbol{y}}}{2\pi c} \tag{D24}$$

$$= \frac{e^{-\frac{r^2}{1+2c}}}{\pi(1+2c)^5} \left[1 - 4r^2 + 2(8c^4 + r^4 + 8c^2r^2 - 4c^2)\right],$$

where  $r^2 = x^2 + p^2$  is the radial coordinate in the phase space. Notice, as a consistency check, that when  $c \to 0$ (D22)-(D24) reduce to the Wigner function of the oscillator eigenstates on the left-hand side. Plugging in (D21) the Wigner function (89) of  $(1-u)|0\rangle\langle 0|+u|1\rangle\langle 1|$  as input state and exploiting (D22) and (D23), we obtain

$$W_{\rm out}(r) = \frac{e^{-\frac{r^2}{1+2c}}}{\pi (1+2c)^3} \left[ (1+2c)^2 + 2u \left( r^2 - 2c - 1 \right) \right] \,. \tag{D25}$$

On the other hand, taking  $(1-u)|1\rangle\langle 1|+u|2\rangle\langle 2|$  as input state and plugging its Wigner function (D10) in (D21), we find

$$W_{\text{out}}(r) = \frac{e^{-\frac{r^2}{1+2c}}}{\pi(1+2c)^5} \left[ (1+2c)^2(1-u)(2r^2+4c^2-1) + u\left(1-4r^2+16c^2+2r^4+16c^2r^2-8c^2\right) \right],$$
(D26)

where we have used both (D23) and (D24). As expected, both the Wigner function (D25) and (D26) become equal to the ones of the corresponding input states when c = 0. Indeed, in that case, the channel we consider reduces to the identity channel.

Finally, we apply the classical mixing channel to the cat states (D17). Plugging (D18) into (D21), in the single-mode case, we obtain the following Wigner function of the output state

$$W_{\pm,\text{out}}^{(\boldsymbol{\alpha})}(\boldsymbol{r}) = \frac{e^{-\frac{|\boldsymbol{r}|^2}{1+2c}}}{\pi(1+2c)} \left[ \frac{e^{2c\frac{|\boldsymbol{\alpha}|^2}{1+2c}} \cosh\left(\frac{2\boldsymbol{\alpha}\cdot\boldsymbol{r}}{1+2c}\right)}{e^{|\boldsymbol{\alpha}|^2} \pm 1} + \frac{e^{\frac{|\boldsymbol{\alpha}|^2}{1+2c}} \cos\left(\frac{2\boldsymbol{\alpha}\cdot\boldsymbol{r}}{1+2c}\right)}{e^{|\boldsymbol{\alpha}|^2} \pm 1} \right].$$

This Wigner function is normalized to one, according to (19), and becomes the input Wigner function (D18) in the limit  $c \to 0$ , as it should.

- [58] Technical and conceptual difficulties will arise when we move to consider non-Wigner positive states, with the Wigner function becoming negative in some domain. For that reason, [57] considered applying continuous majorization in quantum phase space through Husimi Q distributions which are non-negative and difficulties can be avoided. However, here we are motivated by the familiarity of Wigner functions, the connection between quantum advantage and Wigner negativity, and by the resource theories of non-Gaussianity and Wigner negativity. Hence, we focus on Wigner functions.
- [59] Strictly speaking, even a non-negative Wigner function is not an ordinary probability distribution, since the random variables are eigenvalues of non-commuting operators [57] and therefore it could be more appropriately called a

quasi-probability distribution. In this work to simplify the language we use the word probability distribution for a non-negative Wigner function and quasi-probability distribution for non-positive Wigner function.

[60] Result 1 can be proven by plugging (25) into the left-hand side of (4) and performing the change of variables  $y_i = r_i / \sigma_i$ . We obtain

$$\int \left[ \frac{e^{-\frac{1}{2}\boldsymbol{r}^{\mathsf{t}}\boldsymbol{r}}}{(2\pi)^{N}} - t\sqrt{\det\gamma} \right]_{+} d\boldsymbol{r} \equiv \mathcal{I}(t\sqrt{\det\gamma}) \,. \tag{D28}$$

The fact that the function  $\mathcal{I}(x)$  is monotonically decreasing in x and the condition (4) implies Result 1.

[61] We thank Ludovico Lami for pointing out this example.
