Abstract

Recently, large foundation models, including large language models (LLMs) and large vision-language models (LVLMs), have become essential tools in critical fields such as law, finance, and healthcare. As these models increasingly integrate into our daily life, it is necessary to conduct moral evaluation to ensure that their outputs align with human values and remain within moral boundaries. Previous works primarily focus on LLMs, proposing moral datasets and benchmarks limited to text modality. However, given the rapid development of LVLMs, there is still a lack of multimodal moral evaluation methods. To bridge this gap, we introduce M³oralBench, the first MultiModal Moral Benchmark for LVLMs. M³oralBench expands the everyday moral scenarios in Moral Foundations Vignettes (MFVs) and employs the text-to-image diffusion model, SD3.0, to create corresponding scenario images. It conducts moral evaluation across six moral foundations of Moral Foundations Theory (MFT) and encompasses tasks in moral judgement, moral classification, and moral response, providing a comprehensive assessment of model performance in multimodal moral understanding and reasoning. Extensive experiments on 10 popular open-source and closed-source LVLMs demonstrate that M³ oralBench is a challenging benchmark. exposing notable moral limitations in current models. Our benchmark is publicly available¹.

1. Introduction

With rapid advancements in artificial intelligence, large foundation models, including large language models (LLMs) and large vision-language models (LVLMs), have become indispensable tools across fields such as healthcare, law, and finance [1-3]. As these models take on an increasing part in decision-making and daily applications, it is necessary to conduct moral evaluation to ensure that their

outputs align with human values and remain within moral boundaries [4]. Therefore, evaluating the inherent morality of these models has emerged as an urgent task.

Morality has long been a prominent topic in psychology, with a large number of research emerging in the field of moral psychology. Moral Foundations Theory (MFT) [5] stands out as a widely accepted theoretical framework, proposing that core fundamental moral values-developed through evolutionary processes to address social and environmental needs-underpin human morality. With continued development and refinement, the theory identifies six moral foundations: Care/Harm, Fairness/Cheating, Loyalty/Betrayal, Authority/Subversion, Sanctity/Degradation, and Liberty/Oppression [5, 6]. MFT has significant influence on psychology and other related fields, leading to the development of psychometric tools such as Moral Foundations Questionnaire (MFQ) [7], Sacredness Scale (MFSS) [7], and Moral Foundations Vignettes (MFVs) [8], which facilitate cross-cultural and cross-ethnic studies of human moral identity.

In response to the need for moral evaluation of large foundation models, researchers have begun drawing from moral psychology, treating these models as subjects to explore their performance across various moral dimensions [9, 10]. Some studies have applied MFT to model evaluation, directly using or adapting psychological tools like MFQ to assess models' tendencies in specific moral dimensions [9, 11]. Other studies have developed independent morality taxonomy, designing their own moral evaluation datasets and benchmarks [10, 12–16]. However, existing moral evaluation methods primarily focus on LLMs and are limited to text modality, providing a preliminary view of language models' moral understanding. With the emergence of LVLMs, models are now capable of processing combined image and text inputs, allowing them to generate more nuanced moral responses that cross-modality boundaries. Text-only evaluation is insufficient to fully capture the moral judgements and behaviors of multimodal models in real-world scenarios, emphasizing the need for a new

Instruction Generation

Figure 1. An overview of the entire pipeline for M³oralBench construction. We use GPT-40 to expand the Moral Foundations Vignettes, creating a set of moral violation scenarios. For image generation, we further employ GPT-40 to transform these scenarios into image generation prompts with details on location and character, as well as main character dialogues. The moral scenario images are then generated by SD3.0, with dialogues incorporated by speech bubbles. For instruction generation, we apply an instruction template gallery to produce task-specific instructions and reference answers.

multimodal moral evaluation tool.

To bridge this gap, we propose M³oralBench, the first multimodal moral evaluation benchmark. M3oralBench is constructed on MFVs [8], which provide a standardized set of moral scenarios, each briefly describing a behavior that violates a specific moral foundation of MFT. To enhance generalizability and expand the scenario set, we leverage GPT-40 [17] to imitate and create 1,160 everyday moral scenarios in the similar format. For each scenario, we transform it into an image generation prompt specifying details about location and characters, which is then processed by the text-to-image diffusion model SD3.0 [18] to create corresponding moral scenario images. To further enrich the contextual details, we also add a line of dialogue for the main character through a speech bubble, which helps convey character information effectively. Building on this dataset, we design three tasks-moral judgement, moral classification, and moral response-to provide a comprehensive evaluation on the moral understanding and reasoning abilities of LVLMs. Moral judgement task requires the model to determine whether the behavior depicted in the image is morally wrong; moral classification task prompts the model to identify the violated moral foundation; and moral response task challenges the model to choose an appropriate response to the scenario. An overview of the entire pipeline for M³oralBench construction is shown in Figure 1.

Our main contributions are summarized as follows:

• We propose M³oralBench, the first multimodal bench-

mark, to our knowledge, designed to evaluate the moral understanding and reasoning abilities of LVLMs.

- We perform a comprehensive evaluation across 6 moral foundations of MFT and 3 moral tasks, including moral judgement, moral classification, and moral response.
- We conduct extensive experiments on 10 leading opensource and closed-source LVLMs, providing an in-depth analysis of their performance across various moral tasks and moral foundations.

2. Related Work

2.1. Moral Foundations Theory

Moral Foundations Theory (MFT) is a widely accepted theoretical framework in moral psychology [5]. It posits that human moral intuitions stem from several foundational moral dimensions. The first version identifies five moral foundations: Care/Harm (dislike for suffering of others), Fairness/Cheating (proportional fairness, Loyalty/Betrayal (group loyalty), Authority/Subversion (respect for authority and tradition), and Sanctity/Degradation (concerns for purity and contamination) [8]. With development and refinement, Liberty/Oppression, which emphasizes concerns on oppression and coercion [6], has been expanded as the sixth foundation. The multidimensional moral value system of MFT provides theoretical support for understanding human morality. Building on MFT, researchers have developed a range of psychometric tools to quantitatively

study and assess human moral inclinations, including Moral Foundations Questionnaire (MFQ) [7], Sacredness Scale (MFSS) [7], Moral Foundations Vignettes (MFVs) [8]. Among these, MFVs offer a standardized set of scenarios depicting moral violations, enabling researchers to test diverse theories on moral judgement. Our benchmark is constructed based on MFVs.

2.2. Moral Evaluation Datasets and Benchmarks

To ensure models operate within human moral norms, researchers have developed various moral evaluation datasets and benchmarks. ETHICS [12], an early effort in this field, consists of crowdsourced moral judgements in contextualized scenarios. Scruples [13] provides a large-scale collection of real-life anecdotes and ethical dilemmas sourced from the internet, designed to test models' abilities to make judgements and respond to complex ethical situations. MoralExceptQA [15] introduces a challenge set for moral judgements on cases that involve potentially permissible moral exceptions. MoralBench [11] adapts MFQ and MFVs to offer a more nuanced assessment of alignment across different moral dimensions. MoralChoice [10] evaluates models by presenting low-ambiguity and highambiguity moral scenarios to assess responses. CMoralEval [14], which includes Chinese moral anomalies collected from TV programs and newspapers, examines model responses to diverse moral situations, especially for Chinese language models. Similarly, DAILYDILEMMAS [16] explores model responses to complex ethical dilemmas, analyzing the values behind the chosen actions. However, these datasets and benchmarks are primarily designed for LLMs and are limited to text-only modality. To bridge the gap for multimodal moral evaluation benchmark, we propose M³oralBench.

Figure 2. Examples of moral scenarios in MFVs violated different moral foundations.

2.3. Large Vision-Language Models

Building on the success of LLMs, LVLMs have rapidly advanced, achieving remarkable visual perception and reasoning capabilities. Researchers continue to develop stateof-the-art LVLMs through various methods. For example, LLaVA [19] introduces instruction tuning into the multimodal domain, establishing as one of the most mature open-source multimodal models. GLM-4V [20] enhances large language models' visual understanding and question-answering capabilities by integrating visual information. InternLM-XComposer2-VL [21] demonstrates powerful cross-modal reasoning through interactions between multilayered visual encoders and language generation modules. MiniCPM-Llama2-V2.5 [22] combines LLaMA2 with visual encoding modules to achieve streamlined yet efficient multimodal understanding. mPLUG-Owl2 [23], Phi-3-Vision [24], Qwen-VL [25], and Yi-VL [26] further propelled the development of LVLMs. Additionally, many powerful closed-source LVLMs, such as Gemini-1.5-Pro [27] and GPT-40 [17], have released their APIs, driving advancements in downstream applications. We conduct experiments on the above LVLMs to comprehensively evaluate their multimodal moral performance.

3. M³oralBench

3.1. Overview

In this paper, we propose the first multimodal moral benchmark, M³oralBench, which adopts Moral Foundations Theory (MFT) as theoretical framework. We expand the scenarios in Moral Foundations Vignettes (MFVs), creating 1160

Moral Foundations Vignettes

Care: You see a <u>teenage boy</u> chuckling at an <u>amputee</u> he passes by while on the <u>subway</u>.

Moral Violation Scenarios

Care: You see a <u>teenage boy</u> chuckling at an <u>amputee</u> he passes by while on the <u>subway</u>. You see a <u>young man</u> snickering at a <u>blind person</u> using a cane as they exit the <u>bus</u>. You see an <u>adolescent girl</u> giggling at a <u>wheelchair user</u> while crossing the <u>street</u>.

Figure 3. An example of scenario expansion from the MFVs. Character and location details in the scenarios are underlined.

moral violation scenarios across six moral foundations:

- Care/Harm (Care): Virtues of kindness, gentleness, and nurturance; based on empathy and attachment.
- Fairness/Cheating (Fairness): Justice and rights; rooted in reciprocal altruism.
- Loyalty/Betrayal (Loyalty): Group loyalty and self-sacrifice; founded in tribal unity.
- Authority/Subversion (Authority): Respect for hierarchy, leadership, and traditions.
- Sanctity/Degradation (Purity): Purity and self-discipline; influenced by ideas of contamination and spirituality.
- Liberty/Oppression (Liberty): Resistance against oppression; solidarity and freedom.

More detailed explanations of these moral foundations are provided in the Appendix 7. We utilize GPT-4o [17] to create moral scenarios and SD3.0 [18] to generate the corresponding images. To comprehensively evaluate LVLMs on morality in multimodal contexts, we design instruction templates for three moral tasks, i.e., moral judgement, moral classification, and moral response, producing 4640 instructions in total. Detailed data statistics for our benchmark can be found in Table 1.

3.2. Image Generation

We generate moral scenario images based on MFVs. As introduced in Section 2.1, MFVs consist of 116 scenarios depicting violations of moral foundations and 16 scenarios depicting violations of social conventions, each of which is a brief description of a behavior. As our focus on moral evaluation, we only select the 116 scenarios involving moral violations. We provide an example of scenarios in MFVs for each moral foundation in Figure 3.

Moral Violation Scenarios

Care: You see a <u>teenage boy</u> chuckling at an amputee he passes by while on the subway.

Image Generation Prompt

A subway scene with two characters. A smiling teenage boy, wearing casual clothes, walking past. An amputee with a prosthetic leg, sitting on a subway seat.

Main Character Dialogue

Teenage Boy: Haha! Look at him!

Figure 4. An example of image generation prompt and main character dialogue. The main character in the scenario is underlined.

To expand the dataset and improve generalizability, we use GPT-40 to replicate these scenarios, creating 10 diverse versions with identical core events but different characters and locations for each scenario, resulting in a total of 1,160 moral scenarios. An example of scenario expansion is shown in 3.

As the original scenarios are relatively brief, we employ GPT-40 to transform each one into a detailed image generation prompt, including specific details about locations and characters. To clarify the main character's role as the central figure, especially in scenarios involving multiple characters, we also leverage GPT-40 to add a line of dialogue for the main character (the subject of the scenario description). This addition also addresses the limitations of conveying emotions through images alone, as the dialogue provides extra character information and contextual details, enhancing the understanding of the main character's perspective. Figure 4 illustrates an example of the image generation prompt and corresponding dialogue. The specific GPT-40 prompts used in this process can be found in Appendix 8.

We utilize the advanced text-to-image diffusion model, SD3.0, to convert the generated prompts into images. To ensure high-quality outputs, we generate 10 candidate images for each scenario and manually select the image that best aligns with the scenario's description. Specifically, we discard images with quality issues, such as extra limbs, cloned faces or missing arms, retaining those where the characters and locations match the prompt, and the relationships between the main characters are clearly depicted.

We incorporate the dialogues through speech bubbles. Since it is challenging to directly instruct the generation model to produce images with precise speech bubbles, we

Figure 5. Examples of M³oralBench evaluation for different moral tasks. Moral judgement requires the model to assess whether the behavior depicted in the top-left image is morally wrong. Moral classification demands the model to identify the specific moral foundation violated in the top-left image. Moral response challenges the model to choose the appropriate response in the context of the bottom-left images.

opt to edit the images manually. After specifying the position and size of the speech bubbles, the text is automatically added to obtain the final moral scenario images.

3.3. Instruction Design

Existing moral evaluation benchmarks mainly fall into two categories: moral judgement, where the model determines whether a behavior is morally acceptable or identifies which person is morally wrong [11–13, 15]; and moral response, where the model is asked to chooses the action that aligns with moral norms in different contextual scenarios [10, 16]. To enhance the depth and breadth of evaluation, our benchmark introduces an additional task: moral classification. The specific details of each task are explained in the following sections.

Moral Judgement. Moral judgement task evaluates whether the model can accurately determine if the behavior depicted in the scenario image is morally wrong. Since all generated scenarios involve moral violations, to ensure a balanced dataset and enable thorough assessment, we create a contrasting "morally acceptable" version for each moral scenario image by replacing the main character's original dialogue with a morally neutral one. The model is then required to judge these contrasting images simultaneously, allowing us to assess its ability to detect subtle moral differences in similar scenarios and further evaluate its sensitivity and accuracy in moral judgement.

Moral Classification. Moral classification task assesses whether the model can recognize the specific moral foundation violated by the behavior in the scenario image. The options include the six moral foundations (e.g., Care/Harm, Fairness/Cheating) as well as a distractor "not morally wrong". We aim to measure the model's understanding of these moral foundations and its capability to apply this understanding in complex multimodal contexts.

Moral Response. In moral response task, the model is asked to make a choice among two potential responses within a given moral scenario. Specifically, the model is instructed to assume the role of the speaking character in the image and must choose between the previously generated morally violating line and the morally neutral line. Unlike the first two tasks, which explicitly prompt the model to perform intentional moral evaluation, this task is designed to examine whether the model would unintentionally select immoral answers, offering insight into its intrinsic moral tendencies and moral values behind its choices.

Examples of the evaluation for each task are shown in Figure 5. More examples are shown in Appendix 9.

Model	Overall	Moral Tasks					
	0,0101	Judgement	Classification	Response			
GPT-40 [17]	0.726	0.715	0.603	0.860			
Gemini-1.5-Pro [27]	0.672	0.731	0.685	<u>0.600</u>			
GLM-4V [20]	0.574	0.584	0.558	0.581			
Phi-3-Vision [24]	0.478	0.567	0.354	0.513			
mPLUG-Owl2 [23]	0.476	0.595	0.352	0.480			
Yi-VL [26]	0.475	0.563	0.370	0.493			
LLaVA_1.5 [19]	0.457	0.516	0.357	0.499			
MiniCPM-Llama2-V2.5 [22]	0.437	0.544	0.259	0.509			
InternLM-XComposer2-VL [21]	0.433	0.569	0.225	0.503			
Qwen-VL [25]	0.392	0.519	0.141	0.515			

Table 2. Evaluation results on M³ oralBench across 3 moral tasks. The top-2 results are **bolded** and <u>underlined</u>, respectively.

All task instructions are presented as multiple-choice questions. To mitigate the effect of potential position bias in LVLMs [28, 29], i.e., the tendency to choose a certain option in multiple-choice questions, we ensure that the arrangement of options is randomized in all instructions and that the reference options are evenly distributed.

3.4. Evaluation Metric

Moral tasks are inherently complicated and diverse. We aim to accurately capture the model's underlying tendencies under different moral scenarios, assessing the model's moral preferences and consistency more reliably. To achieve this, we quantify the model's likelihood of choosing each option in a given multimodal scenario by calculating the probability of each choice, thus providing a reliable foundation for subsequent analysis.

Due to the computational complexity involved in mapping token space to option space and the fact that some closed-source model APIs do not provide direct access to token probabilities[10], we estimate these probabilities through Monte Carlo sampling [30]. Specifically, for the LVLM with parameters θ , we sample M responses $\{a_1, ..., a_M\}$ by $a \sim p_{\theta_j}(a|i, t)$ for each image-instruction pair $(i, t) \in I \times T$. The likelihood of choosing a specific option o_i is quantified as follows:

$$\hat{p}_{\theta}(o_i|i,t) = \frac{1}{M} \sum_{j=1}^{M} \mathbb{I}[a_j = o_i].$$
(1)

We consider the option with the highest probability as the model's preference option for each image-instruction pair and calculate the accuracy as the evaluation metric. Higher accuracy indicates better abilities in moral understanding and reasoning, with greater alignment between the model's intrinsic moral inclinations and human moral standards. The average accuracy across the three tasks is considered as the overall score.

4. Experiments

4.1. Experimental Setup

We evaluate our M³oralBench on 8 popular open-source LVLMs, GLM-4V [20], Phi-3-Vision [24], mPLUG-Owl2 [23], Yi-VL [26], LLaVA_1.5 [19], MiniCPM-Llama2-V2.5 [22], InternLM-XComposer2-VL [21], and Qwen-VL [25], as well as 2 powerful closed-source LVLMs, GPT-40 [17] and Gemini-1.5-Pro [27]. For each image-instruction pair in the benchmark, we set M = 5, i.e., generating 5 responses from each model, to obtain their preference options. The temperature is set to 1.0 during evaluation to control the randomness of the generated responses.

4.2. Evaluation Results

Overall Performance. Table 2 illustrates the moral evaluation results of all LVLMs on M³oralBench. Overall, closedsource models outperform open-source models, with GPT-40 achieving the highest score, followed by Gemini-1.5-Pro. This disparity can be attributed to the fact that closedsource models are primarily designed for commercial purposes, with a stronger emphasis on alignment with human values, particularly in addressing issues related to safety, ethics, and preventing harmful outputs. Commercial companies like OpenAI and Google typically implement dedicated moral review mechanisms to ensure that their models' outputs adhere to ethical standards. As a result, closedsource models generally demonstrate superior performance in moral evaluations.

Among open-source models, GLM-4V demonstrates the best overall performance, achieving close results in moral response task to closed-source models. During the evaluation, we observe that several open-source models struggle to consistently adhere to instructions. We think it may be due to the challenging and novel nature of multimodal moral

Figure 6. Comparison of the top-5 LVLM performance across 6 moral foundations on M³oralBench. A larger area indicates better performance.

tasks. Despite explicit prompts directing the models to respond solely with the provided options, there is still a small probability of generating irrelevant answers. This suggests that certain open-source models exhibit foundational limitations, which impede their performance in moral evaluations.

Performance across Moral Tasks. As shown in Table 2, most models exhibit relatively lower performance in moral classification than in the other two tasks, with an average accuracy rate under 40%. This indicates that moral classification is likely the most challenging task in the benchmark. This result is intuitive, as the task requires the model not only to understand binary moral judgement, but also to reason about the underlying causes of moral wrongness, which places a significant demand on the model's comprehension of moral principles.

While GPT-40 achieves the highest overall score, it does not consistently outperform other models on every task. This is partly due to GPT-40 occasionally refusing to answer certain questions, with responses such as "*I'm sorry*, *I can't assist with that*." This issue is consistent with results from other benchmarks [10]. To address this, we modify the prompts to clearly instruct the model not to reply with such statements. Although this modification lead to some improvement, it could not entirely eliminate the issue.

Performance across Moral Foundations. We select the top-5 LVLMs from M³oralBench evaluation to conduct a detailed analysis of their performance across different moral foundations. Figure 6 visually presents the comparison results of these models, with the complete results available in Appendix 10. From Figure 6, we observe that most LVLMs demonstrate the best moral performance on Care/Harm and Fairness/Cheating foundations, aligning more closely with human values. This is understandable, as issues related to these two foundations, such as toxicity and bias, are prominent topics in large model research currently. Significant efforts have been made by researchers to improve model performance in these areas.

In contrast, Loyalty/Betrayal and Sanctity/Degradation

Moral Foundations	Wrong Rating	Wrong%
Care/Harm	2.79	0.938
Fairness/Cheating	2.80	0.965
Loyalty/Betrayal	1.99	0.821
Authority/Subversion	2.34	0.899
Sanctity/Degradation	2.81	0.888
Liberty/Oppression	2.57	0.916

Table 3. Results from the study conducted with human respondents in MFVs [8]. **Wrong Rating** represents the average moral wrongness ratings for scenarios in each moral foundation on a 5-point scale, where 0 = not at all wrong, 1 = not too wrong, 2 = somewhat wrong, 3 = very wrong, and 4 = extremely wrong. Wrongness% indicates the average proportion of scenarios classified as morally wrong in each moral foundation.

foundations reveal relatively greater limitations of LVLMs on morality. For Loyalty/Betrayal, although loyalty is recognized as an important moral value, human tolerance for its violation tends to be higher in many real-world contexts. Regarding Sanctity/Degradation, the content involved in sanctity violations, such as sexually deviant acts and degrading behaviors, touches on highly sensitive issues within human societies. As a result, when models attempt to address these aspects, they may struggle to accurately recognize and evaluate such complex and sensitive moral situations, often due to insufficient moral judgement mechanisms or a lack of adequate training data. The challenges in these two moral foundations are substantial, which deserve further exploration in future research.

Comparison with MFVs Results. Table 3 presents the results of the study in MFVs conducted with human respondents [8]. The findings from MFVs on human moral judgement align with certain aspects of our M³oralBench evaluation of LVLMs. For example, in moral violation scenarios related to Care/Harm and Fairness/Cheating, human respondents assign high average moral wrongness scores,

Figure 7. Visualization of the correlations between the moral evaluation results of the evaluated LVLMs across various moral tasks and foundations. The correlations are calculated using Pearson correlation coefficients.

with over 90% considering these scenarios as morally wrong. This suggests that human participants have a clear and strong understanding of these two moral foundations, and most models also perform best on these foundations, aligning with human results.

Notably, Sanctity/Degradation foundation receives the highest wrong rating among all foundations in MFVs results, indicating that sanctity violations are typically regarded as the most severe moral transgressions by humans. However, most LVLMs exhibit the poorest moral performance on this foundation, highlighting a significant gap between the model's understanding of the Sanctity foundation and human values, underscoring the need to improve model comprehension in this moral foundation.

Model Consistency. We also conduct a correlation analysis of different LVLMs on moral performance. As visualized in Figure 7, we calculate the Pearson correlation coefficients between the moral evaluation results of these models across various moral tasks and foundations. The highperforming models in moral evaluation, including GPT-40, Gemini-1.5-Pro, and GLM-4V, form a separate cluster, indicating that these advanced LVLMs exhibit similar patterns in their moral evaluation performance across different moral tasks and foundations, leading to strong correlations in their overall moral evaluation scores.

In contrast, the remaining open-source models form another distinct cluster with higher internal correlations, primarily because these models show consistent yet generally weaker results across most moral tasks, highlighting a gap in moral capabilities between the two clusters of models.

5. Discussion

Ethical and Social Concerns. Our research performs a multimodal moral evaluation of LVLMs, probing potential moral issues within these models. All images in our benchmark are generated by SD3.0, and we have manually verified that they contain no identifiable data or depictions of explicit violence or gore, ensuring no adverse impact on individuals or communities. While the benchmark includes moral violation scenarios that may be offensive or evoke discomfort, our aim is to provide new insights into the inherent moral understanding in LVLMs. We expect that our work will contribute to the development of reliable and safe AI models that are highly aligned with human values.

Limitations. There exists certain limitations in our benchmark. On one hand, our moral scenario images are generated by the text-to-image diffusion model, SD3.0. Although SD3.0 is one of the most advanced generative models available, its outputs can still exhibit issues, such as extra limbs or cloned faces. We have manually filtered out images with obvious quality problems during the generation process to mitigate these effects. Secondly, we convey scene information through a multimodal approach by adding textual dialogue to the images, rather than using purely visual input. This design choice prevents us from isolating the influence of each modality on the model's moral abilities. Additionally, our instructions are relatively limited, relying solely on closed-ended multiple-choice questions without including open-ended VQA. We will explore ways to address these limitations in future work.

6. Conclusion

In summary, we propose M3oralBench, to our knowledge, the first multimodal moral evaluation benchmark for LVLMs. M³oralBench is grounded in Moral Foundation Theory and builds upon the scenarios in Moral Foundation Vignettes that depict violations of six distinct moral foundations. We expand this set of scenarios using GPT-40 and generate corresponding moral scenario images with SD3.0. To provide a comprehensive evaluation of models' inherent morality, we design instructions for three distinct moral tasks: moral judgement, moral classification, and moral response. Our extensive experimental results on ten prominent open-source and closed-source LVLMs indicate that closed-source models currently outperform opensource models in moral ability. However, there is still room for improvement, particularly in understanding and adhering to the moral foundations of Loyalty/Betrayal and Sanctity/Degradation.

M³oralBench: A MultiModal Moral Benchmark for LVLMs

Supplementary Material

7. Moral Foundations Theory

7.1. Moral Foundations

We provide a more detailed explanation of the six moral foundations [5, 6] as follows:

- **Care/Harm**: This foundation arises from the evolutionary need to care for vulnerable offspring. It is triggered by visual and auditory signs of suffering, distress, or neediness, primarily from one's own children but also from other children, animals, or even representations like stuffed toys. It underpins virtues such as kindness and compassion while opposing cruelty, and its expression varies across cultures.
- Fairness/Cheating: Rooted in the need for reciprocal relationships, this foundation is evolved to detect cheating and cooperation. It motivates tit-for-tat responses and fairness judgements, extending beyond direct interactions to include third-party evaluations and even inanimate exchanges. It promotes virtues like justice and trustworthiness.
- Loyalty/Betrayal: Emerging from the benefits of cohesive coalitions in intergroup competition, this foundation supports group loyalty and solidarity. Originally activated by tribal and intergroup dynamics, it now extends to modern phenomena like sports fandom and brand allegiance. Loyalty is praised, while betrayal is condemned.
- Authority/Subversion: This foundation is based on navigating dominance hierarchies effectively to gain social advantages. It governs interactions with authority figures and institutions and is associated with virtues like obedience and deference in hierarchical societies. Its interpretation varies across cultures and political ideologies.
- Sanctity/Degradation: Evolving as a behavioral immune system to avoid pathogens and parasites, this foundation is linked to disgust and reactions to impurity. It manifests in moral judgements about dietary practices, bodily integrity, and social deviance, often promoting virtues like temperance and chastity in certain cultures.
- Liberty/Oppression foundation: This foundation centers on the feelings of reactance and resentment toward those who dominate or restrict individual freedom. It is motivated by the hatred of bullies and oppressors, driving people to unite in solidarity to resist or overthrow domination. While it often conflicts with the authority foundation, it fosters virtues such as independence, equality, and the courage to oppose injustice.

7.2. Moral Foundations Vignettes

Moral Foundations Vignettes (MFVs) [8] are carefully constructed scenarios designed to isolate and evaluate specific moral foundations by reflecting their core principles. These vignettes are tailored to represent plausible everyday events, avoiding overtly political or culturally bound content, and are formulated to encourage respondents to imagine themselves as third-party witnesses to moral violations. Compared to other moral questionnaires that may involve relatively abstract concepts, MFVs provide concrete, thirdperson scenarios rooted in everyday life. This specificity makes them particularly suitable for visualization, enabling the construction of moral scenario image for our benchmark.

Care violation scenarios focus on three types of harm: emotional harm to humans, physical harm to humans, and physical harm to non-human animals.

Fairness violation scenarios emphasize instances of cheating or free-riding, such as dishonesty in work or academic settings.

Loyalty violations are framed around individuals prioritizing personal interests over group loyalty. Groups are defined broadly to include family, country, or organizations, and scenarios feature public behavior that threatens group reputation.

Authority violations involve disobedience or disrespect toward authority figures (e.g., parents, teachers, judges) or institutions (e.g., courts, police).

Sanctity vignettes feature violations that evoke physical disgust, such as contamination concerns or sexually deviant acts. Examples include behaviors like eating a dead pet dog or urinating in a public pool.

Liberty scenarios depict coercive actions or restrictions on freedom, typically imposed by those in positions of power (e.g., a boss or parent).

8. Image Generation Details

8.1. Image Generation Prompts

In image generation process, we utilize GPT-40 [17] to expand the dataset by imitating similar scenarios from MFVs and converting these brief descriptions into detailed image prompts and main character dialogues. Additionally, to generate two contrasting versions of the scenarios, a morally wrong line and a morally neutral line of dialogue is created for each main character in the scenarios. The specific prompts used for these processes are shown in Figure 8 and Figure 9.

Imitate the given scenario and generate several similar ones. Keep the same format and maintain the core content of the scenario. The details about characters or location can be varied.

###Example:

Scenario: You see a woman commenting out loud about how fat another woman looks in her jeans. Output:

Scenario 1: You see a girl loudly pointing out how oversized her friend looks in a new dress at a school party. Scenario 2: You see a man commenting out loud about how fat a young woman looks in her swimsuit at the pool.

Now apply this format to the following scenario and generate 10 similar scenarios.

Scenario: [*The Scenario in MFVs*] Output:

Figure 8. The prompt used to expand the scenarios in MFVs.

Transform the following scenario into a detailed image description with main character dialogues. The description should only focus on the main characters and the location. Only the main character, which is the subject of the scenario, may have one brief line of dialogue to express their emotions or feelings. Generate one original line that aligns with the main character's emotions in the scenario, and another line that represents an opposite or neutral emotional perspective.

###Example: Scenario: You see a boy ridiculing his teammate for missing a goal during the soccer tryouts. Output: Description: A soccer field scene with two characters. A boy, wearing a sports jersey, pointing at another boy. Another boy in a soccer uniform, standing near the goal looking down. Original Line: Haha! You missed it! Opposite Line: Let's try again. Now apply this format to the following scenario. Scenario: [*The Moral Violation Scenario*]

Figure 9. The prompt used to transform the moral violation scenarios into image descriptions and main character dialogues.

8.2. Image Generation Quality

Output:

To evaluate the quality of the generated moral scenario images and their alignment with the original moral violation scenario texts, we employ GPT-40 [17] to generate brief captions for the images. We then calculate the average CLIP similarity between these captions and the original scenario text. The results, summarized in Table 4, show that the average similarity score exceeds 0.75, with scores surpassing 0.77 for Care, Fairness, Authority, and Liberty foundations. These results demonstrate that the generated images are highly consistent with the corresponding scenario text, which ensures that the scenarios depicted in the images are accurately understood by the models, verifying the reliability of our benchmark.

9. More Evaluation Examples

More examples of M³oralBench evaluation are shown in Figure 10, Figure 11 and Figure 12.

Foundation	CLIP Similarity
Overall	0.765
Care	0.771
Fairness	0.774
Loyalty	0.751
Authority	0.779
Sanctity	0.734
Liberty	0.777

Table 4. Average CLIP similarity scores between scenario image captions and original scenario texts for each moral foundation.

10. Detailed Evaluation Results

We provide the detailed evaluation results on M³oralBench across 3 moral tasks and 6 moral foundations in Table 5, Table 6 and Table 7.
