Abstract

Multimodal large language models (MLLMs) have achieved significant advancements in integrating visual and linguistic understanding. While existing benchmarks evaluate these models in context-rich, real-life scenarios, they often overlook fundamental perceptual skills essential for environments deviating from everyday realism. In particular, geometric perception, the ability to interpret spatial relationships and abstract visual patterns, remains underexplored. To address this limitation, we introduce GePBench, a novel benchmark designed to assess the geometric perception capabilities of MLLMs. Results from extensive evaluations reveal that current state-of-the-art MLLMs exhibit significant deficiencies in such tasks. Additionally, we demonstrate that models trained with data sourced from GePBench show notable improvements on a wide range of downstream tasks, underscoring the importance of geometric perception as a foundation for advanced multimodal applications. Our code and datasets will be publicly available.

1 Introduction

Multimodal large language models (MLLMs) have achieved significant breakthroughs in recent years. Closed-source models like GPT-4o [\(OpenAI,](#page-10-0) [2023\)](#page-10-0), Gemini [\(Google,](#page-9-0) [2023\)](#page-9-0), and Claude-3.5 [\(Anthropic,](#page-8-0) [2024\)](#page-8-0), along with open-source alternatives such as LLaVA [\(Liu et al.,](#page-9-1) [2023a\)](#page-9-1), Qwen-VL [\(Bai et al.,](#page-8-1) [2023\)](#page-8-1), and InternVL [\(Chen et al.,](#page-8-2) [2023b\)](#page-8-2), have demonstrated remarkable visuallanguage capabilities. To measure their performance, various benchmarks including GQA [\(Hud](#page-9-2)[son and Manning,](#page-9-2) [2019\)](#page-9-2), SQA [\(Lu et al.,](#page-10-1) [2022\)](#page-10-1), TextVQA [\(Singh et al.,](#page-10-2) [2019\)](#page-10-2), and MMBench [\(Liu](#page-9-3) [et al.,](#page-9-3) [2024c\)](#page-9-3) have been proposed. These benchmarks primarily assess models in context-rich, reallife scenarios, simulating everyday human experiences. However, they often neglect fundamental

perceptual challenges, particularly in domains that deviate from everyday realism.

One such underexplored domain is geometric perception. As simplified abstractions of realworld objects, geometric shapes require an understanding of spatial relationships and visual details for effective perception [\(Chen et al.,](#page-8-3) [2021;](#page-8-3) [Lu](#page-10-3) [et al.,](#page-10-3) [2021;](#page-10-3) [Chen et al.,](#page-8-4) [2022\)](#page-8-4). Therefore, they are ideal for testing the foundational visual capabilities. More complex tasks like visual reasoning and decision-making build on these basic perceptual abilities, making it crucial to assess models' competencies in geometric environments. Furthermore, geometric shapes lay the foundation for a wide range of downstream applications. For example, tasks like medical image analysis [\(Chen et al.,](#page-8-5) [2024b;](#page-8-5) [Yan et al.,](#page-10-4) [2024;](#page-10-4) [Khan et al.,](#page-9-4) [2024\)](#page-9-4) and fossil classification [\(Barucci et al.,](#page-8-6) [2024;](#page-8-6) [Hou et al.,](#page-9-5) [2023\)](#page-9-5) rely heavily on precise spatial perception and the interpretation of abstract visual patterns, which are closer to geometric shapes than to real-world images. Despite their importance, existing benchmarks fail to adequately evaluate these fundamental skills, leaving critical gaps in the assessment of MLLMs.

To address this gap, we present GePBench, a novel benchmark specifically designed to evaluate the geometric perception capabilities of MLLMs. GePBench focuses exclusively on geometric shapes and assesses core competencies such as spatial perception and shape understanding. While humans achieve near-perfect accuracy on these tasks with minimal effort, leading models like GPT-4o and Claude-3.5-Sonnet struggle significantly. On tasks such as determining the size of a geometric shape, they achieve accuracies as low as 23.3% and 20.8% respectively, well below random guessing. These results underscore the limitations of current MLLMs in basic geometric perception.

Although some existing multimodal benchmarks, such as GeoQA [\(Chen et al.,](#page-8-3) [2021\)](#page-8-3), Geometry3K

Figure 1: Examples for the different dimensions of GePBench.

[\(Lu et al.,](#page-10-3) [2021\)](#page-10-3), UniGeo [\(Chen et al.,](#page-8-4) [2022\)](#page-8-4), geomVerse-V0 [\(Kazemi et al.,](#page-9-6) [2023\)](#page-9-6), GeoMM [\(Deng et al.,](#page-8-7) [2024\)](#page-8-7), and MAVIS-Instruct [\(Zhang](#page-11-0) [et al.,](#page-11-0) [2024\)](#page-11-0), also involve geometric figures, their primary focus lies in mathematical reasoning tasks, including numeric calculations, proof generation, and relationship inference. These higher-order cognitive tasks implicitly depend on basic perceptual skills like spatial awareness and shape recognition, which are often insufficiently addressed. In contrast, GePBench explicitly targets foundational visual capabilities, providing a more focused and comprehensive evaluation on these fundamental capabilities.

To construct GePBench we developed a specialized data synthesis engine that generates structured textual descriptions, which are subsequently translated into geometric figures. From these figures, corresponding multiple-choice questions are formulated to evaluate key dimensions of spatial and shape perception. GePBench comprises 20K images and 250K multiple-choice questions, categorized into easy and hard levels based on factors such as the number of shapes in a figure and the intensity of added noise. The benchmark evaluates 6 key dimensions of spatial and shape perception: location, size, existence, counting, reference, and relationships. Figure [1](#page-1-0) provides examples for these dimensions.

We conducted extensive evaluations of GeP-Bench using a diverse array of MLLMs, encompassing both closed-source and open-source models. The results consistently reveal significant limitations in geometric perception. Even the topperforming model, Gemini-1.5-pro, achieves an average accuracy of only 69.4% on these multiple choice questions, highlighting the urgent need for advancements in foundational geometric understanding.

Furthermore, we observe that LLaVA-GeP, our newly trained model with additional data sourced from GePBench demonstrate considerable improvements on various downstream tasks, particularly those involving spatial perception and diagram understanding. This underscores the pivotal role geometric perception plays in enabling broader applications.

Our contributions are summarized as follows:

- 1) We introduce GePBench, a novel benchmark focusing on the fundamental visual perception and spatial understanding of MLLMs.
- 2) We conduct extensive evaluations with 21 stateof-the-art models, identifying key technical challenges in geometric perception and providing insights into potential improvements.
- 3) We demonstrate that our model, LLaVA-GeP, achieves improved visual capabilities, highlighting GePBench as an effective tool for enhancing

basic visual perception skills, which are transferable to real-world applications.

2 Related Work

2.1 Multimodal Large Language Models

In recent years, MLLMs have gained considerable attention for their ability to perform cross-modal understanding across a wide range of real-world tasks [\(Liu et al.,](#page-9-1) [2023a;](#page-9-1) [Zhu et al.,](#page-11-1) [2024;](#page-11-1) [Yao et al.,](#page-10-5) [2024;](#page-10-5) [Chen et al.,](#page-8-2) [2023b;](#page-8-2) [Lu et al.,](#page-9-7) [2024a;](#page-9-7) [Tong](#page-10-6) [et al.,](#page-10-6) [2024a\)](#page-10-6). These models typically consist of three main components: a visual encoder responsible for encoding the input image, a language model that enables textual understanding and reasoning, and a mapping module that translates visual features into textual representations. While they have shown remarkable success in real-life scenarios, their performance on foundational tasks, such as spatial perception and understanding abstract shapes, remains underexplored. This work aims to investigate the extent to which MLLMs can capture fine-grained visual features and exhibit spatial awareness in environments involving geometric shapes.

2.2 Multimodal Benchmarks

Numerous multimodal datasets have been proposed to benchmark the performance of MLLMs, with a focus on real-world tasks [\(Kembhavi et al.,](#page-9-8) [2016;](#page-9-8) [Yue et al.,](#page-10-7) [2024;](#page-10-7) [Chen et al.,](#page-8-8) [2024a;](#page-8-8) [Liu et al.,](#page-9-9) [2023b\)](#page-9-9). Early benchmarks such as VQAv2 [\(Goyal](#page-9-10) [et al.,](#page-9-10) [2019\)](#page-9-10), GQA [\(Hudson and Manning,](#page-9-2) [2019\)](#page-9-2), and ScienceQA [\(Lu et al.,](#page-10-1) [2022\)](#page-10-1) aim at evaluating tasks like object identification, optical character recognition, and scientific knowledge. Later, structured datasets such as MMBench [\(Liu et al.,](#page-9-3) [2024c\)](#page-9-3) and SeedBench [\(Li et al.,](#page-9-11) [2023a\)](#page-9-11) are introduced, offering more difficult challenges and better evaluation schemes. However, these benchmarks predominantly emphasize real-life, contextrich tasks, overlooking different environments that require fundamental spatial and visual perception.

A separate line of research has focused on evaluating the geometric mathematical reasoning capabilities of MLLMs. Early works adapted images from mathematical textbooks or exam problems, creating question-answer pairs centered on reasoning tasks like calculations, proof generation, and relationship inference [\(Chen et al.,](#page-8-3) [2021;](#page-8-3) [Lu et al.,](#page-10-3) [2021;](#page-10-3) [Chen et al.,](#page-8-4) [2022;](#page-8-4) [Lu et al.,](#page-9-12) [2024b\)](#page-9-12). More recent approaches have automated the generation of

these tasks [\(Deng et al.,](#page-8-7) [2024;](#page-8-7) [Zhang et al.,](#page-11-0) [2024\)](#page-11-0). They craft figures using specific data engines and construct questions and answers with the help of LLMs. Nevertheless, these benchmarks primarily target long-chain mathematical reasoning and often overlook spatial perception and fine-grained visual understanding, areas that GePBench aims to address.

3 GePBench

GePBench is a novel benchmark designed to evaluate the geometric perception capabilities of MLLMs. It leverages a systematic data synthesis pipeline to generate structured textual descriptions of geometric figures, from which corresponding images and multiple-choice questions are constructed. This approach enables a comprehensive assessment of models across multiple dimensions of spatial and visual understanding. An overview of the GeP-Bench data pipeline is shown in Figure [2.](#page-3-0) Below, we detail the design and construction of GePBench, focusing on its description generation methodology, figure rendering technique and task formulation framework.

3.1 Structured Description Generation

The foundation of GePBench lies in generating structured textual descriptions, which serve as the basis for both figure creation and question generation. This process ensures consistency and precision in data construction.

Algorithm [1](#page-4-0) describes the entire generation process. It begins by randomly sampling shapes from a predefined pool containing 10 geometric types (e.g., lines, ellipses, circles, triangles, quadrilaterals, pentagons, hexagons, rectangles, squares, and spirals). Attributes such as position, size, and orientation are assigned randomly to these shapes. To introduce meaningful complexity, specific shapes are further added to the figure based on 9 different predefined geometric relationships (e.g., tangent, parallel, inscribed). This ensures the dataset includes diverse spatial configurations.

To maintain clarity, a filtering step checks for excessive overlaps or out-of-bound shapes, ensuring that generated figures remain interpretable. The output is a structured textual description containing shape types, attributes, and relationships.

3.2 Figure Rendering

Next, figures are rendered from these descriptions using the Matplotlib package [] in Python. To in-

Figure 2: An overview of the construction of GePBench.

crease task difficulty, visual noise is added to part of the figures, including Gaussian noise for the background, salt-and-pepper noise on shape outlines, and Perlin noise [] for closed shapes. This enhances the robustness of the benchmark by challenging models to perform under visually degraded conditions.

3.3 Task Formulation

Once figures and textual descriptions are generated, a template-based pipeline constructs multiplechoice questions across six key dimensions, each designed to evaluate distinct aspects of geometric perception. Below, we describe the six dimensions and their associated question-generation strategies.

Existence. These questions assess the model's ability to recognize specific shapes and avoid hallucinations. Instead of simple binary queries, GeP-Bench incorporates more nuanced formats, such as asking the model to identify which shapes appear in the figure from a list of options. This design increases the task's difficulty and better evaluates models' shape discrimination abilities.

Counting. Counting questions focus on determining the number of specific shapes in a figure. To ensure robustness, non-existent shapes are included as distractors, and zero is provided as a candidate choice.

Location. Location-based questions test the spatial perception capabilities of models. Figures are divided into four quadrants (upper-left, upper-right, lower-left, lower-right), and models must identify the quadrant containing a target shape based on

its centroid. Additional questions involve relative positioning, requiring models to determine spatial relationships between shapes.

Size. These questions evaluate the model's ability to perceive and compare shape sizes. Attributes such as horizontal span, vertical span, and area are queried. To standardize the evaluation, the image dimensions are normalized to 1, and the numeric intervals between candidate answers are sufficiently large to prevent ambiguity.

Reference. Reference questions reverse the typical query format by providing attributes (e.g., size, location, or count) and asking the model to identify the corresponding shape. This perspective evaluates the integration of multiple attributes for shape identification.

Relationship. Questions in this dimension explore geometric relationships between pairs of shapes, such as tangent, parallel, or inscribed. These tasks test the model's understanding of spatial interactions and its ability to discern finegrained geometric details.

By incorporating different question dimensions, we aim to provide a comprehensive evaluation protocol for geometric perception in MLLMs.

3.4 Statistics and Analysis

According to the statistics, GePBench contains a total of 20K geometric figures and 250K multiple choice questions. The dataset sizes for each of the 6 dimensions are outlined in Figure [3](#page-4-1) (a).

GePBench features a diversity of geometric shapes and question types. Detailed statistics are

presented in Figure [3](#page-4-1) (b) (c), including the number of shapes per figure and question length, highlighting its balanced coverage across geometric types and question categories. Overall, GePBench provides a rigorous and diverse evaluation benchmark, challenging MLLMs with tasks that test foundational geometric perception and spatial reasoning. By focusing on these core capabilities, GePBench fills a critical gap in the landscape of multimodal benchmarks.

4 Experiments

4.1 Experimental Setup

Evaluated models. We perform a comprehensive evaluation on GePBench for 21 multimodal LLMs, which are divided into 2 groups: closed-source model classes, including GPT-4o, Claude-3.5- Sonnet, Gemini-1.5-Pro, and open-source model classes, including BLIP2 [\(Li et al.,](#page-9-13) [2023b\)](#page-9-13), Instruct-BLIP [\(Dai et al.,](#page-8-9) [2023\)](#page-8-9), MiniGPTv2 [\(Chen et al.,](#page-8-10) [2023a\)](#page-8-10), LLaVA-1.5 [\(Liu et al.,](#page-9-14) [2024a\)](#page-9-14), LLaVA-NeXT [\(Liu et al.,](#page-9-15) [2024b\)](#page-9-15), mPLUG-Owl3 [\(Ye](#page-10-8) [et al.,](#page-10-8) [2024\)](#page-10-8), InternVL-2.5 [\(Chen et al.,](#page-8-11) [2024c\)](#page-8-11), MiniCPM-V-2.6 [\(Yao et al.,](#page-10-5) [2024\)](#page-10-5), GLM-4V [\(GLM et al.,](#page-8-12) [2024\)](#page-8-12), Mantis-Idefics2 [\(Jiang et al.,](#page-9-16) [2024\)](#page-9-16), Qwen2-VL [\(Wang et al.,](#page-10-9) [2024\)](#page-10-9), LLaMA-3.2-Vision [\(Meta,](#page-10-10) [2024\)](#page-10-10).

Evaluation setup. All evaluations are conducted exclusively in a zero-shot manner. For a fair comparison, the temperature is set to 0 and the image resolution is set to 640x640. Accuracy for multiple choice questions are utilized for all the question categories. We conduct all experiments on NVIDIA A6000 GPUs with 48GB VRAM.

4.2 Main Result

The main experimental results are presented in Table [1.](#page-5-0) To better contextualize the performance of GePBench models in real-world tasks, we also include their results on OpenCompass [\(Contributors,](#page-8-13) [2023\)](#page-8-13), visualized in Figure [4.](#page-6-0) Our analysis reveals the following key observations:

Both closed-source and open-source models face significant challenges on GePBench. The results indicate that even the most advanced closedsource models encounter significant challenges when evaluated on our geometric perception tasks.

Model Class	Size	Avg.		Easy							Hard

Table 1: Performance comparison of different MLLMs on GePBench (%). Ext, Cnt, Siz, Loc, Ref, Rel represent existence, counting, size, location, reference, relationship, and Avg is the average value of all the 12 following scores. Best scores for each group are in bold. Average scores that reach the passing threshold (60.0%) is underlined.

Performance is especially low in the size and location dimensions, where fundamental spatial reasoning is required. For instance, GPT-4o and Claude-3.5-Sonnet achieve accuracy rates of only 23.3% and 20.8% respectively on the size dimension, failing to surpass random guessing. While Gemini-1.5 pro stands out as the best-performing closed-source model, it still struggles to deliver satisfactory results across all tasks. These findings underscore the rigorous demands posed by our dataset and highlight its value in testing the limits of state-of-theart systems. In comparison, open-source models perform even worse overall. Notable exceptions include InternVL-2.5 and Qwen2-VL, whose performance is comparable to leading closed-source models. However, the majority of open-source models fall below the passing threshold. This disparity suggests that open-source models currently exhibit significant limitations in geometric perception, leaving substantial room for advancement.

Scaling model size yields limited improvements.

Unlike many real-world tasks where larger model sizes result in significant performance gains, scaling has a more limited impact on geometric perception tasks. For instance, increasing the size

of Qwen2-VL from 8B to 72B improves accuracy by only 3.9%. Similarly, scaling LLaVA-NeXT from 7B to 72B results in a modest 7.1% improvement, while InternVL's expansion from 7B to 78B yields an 8.2% gain. These improvements are far less pronounced than those observed on general benchmarks, which are 7.8%, 23.3%, and 7.1%, respectively. This trend likely arises because the advantages of scaling, such as enhanced logic and reasoning, are less applicable in geometric perception tasks, which emphasize fundamental visual capabilities. Consequently, optimizing model architectures or enhancing training datasets may be more effective strategies for improving performance in these tasks.

Models typically perform better on the easy split than on the hard split. As previously described, the GePBench dataset divides questions into easy and hard splits based on the number of shapes per figure and the intensity of visual noise. Both closedsource and open-source models generally perform better on the easy split. This performance gap is particularly pronounced in the relationship and counting dimensions, with average accuracy differences of 12.2% and 10.4%, respectively. This dis-

Figure 4: Performance comparison of representative models on GePBench and OpenCompass. Larger dots indicate larger model sizes.

Figure 5: Performance comparison of representative models on questions categorized by different number of geometric shapes in the figure.

parity is expected, as increased shape complexity and degraded visual details in the hard split significantly challenge relationship recognition and shape understanding. In contrast, dimensions focused on spatial perception, such as size and location, are less affected by these factors.

4.3 Ablation Analysis

This section examines the factors influencing model performance, focusing on both data attributes and the components of MLLMs.

4.3.1 Impact of the Number of Shapes

The number of geometric shapes per figure can significantly affect model performance. A higher number of shapes increases the complexity of visual perception while offering more challenges in cognition. To investigate this, we categorize the

questions in GePBench based on the number of shapes in the figures and evaluate model performance across these groups.

The results, shown in Figure [5,](#page-6-1) reveal a general decline in performance as the number of shapes increases. This trend aligns with our expectation that figures with more shapes demand a greater capacity for geometric perception. Such findings underscore the need for models to develop stronger foundational visual perception skills to handle more complex inputs.

4.3.2 Impact of Visual Encoders

As discussed in Section [2.1,](#page-2-0) visual encoders are central to the visual perception capabilities of MLLMs. To assess their influence, we experiment with the LLaVA-1.5-7B model using various visual encoders, including CLIP-ViT-L, CLIP-ViT-L-336 [\(Radford et al.,](#page-10-11) [2021\)](#page-10-11), OpenCLIP-ViT-L [\(Cherti](#page-8-14) [et al.,](#page-8-14) [2023\)](#page-8-14), DINOv2 [\(Oquab et al.,](#page-10-12) [2024\)](#page-10-12) and SigLIP [\(Zhai et al.,](#page-10-13) [2023\)](#page-10-13). Additionally, following the empirical best practice [\(Tong et al.,](#page-10-14) [2024b;](#page-10-14) [Yang et al.,](#page-10-15) [2024\)](#page-10-15), we evaluate mixed configurations where outputs from both the CLIP-ViT-L and DINOv2 encoders are fed into the LLM backbone. The checkpoints for these models are sourced from [Yang et al.](#page-10-15) [\(2024\)](#page-10-15) and evaluated on GePBench.

The results, summarized in Table [2,](#page-7-0) provide the following insights:

Higher resolution improves detail recognition but impacts spatial accuracy. Using a higher resolution in the CLIP-ViT encoder generally enhances geometric perception, except for locationbased tasks. This is likely due to that more image tokens enables the inclusion of finer image details, benefiting the overall performance. However, it also increases the complexity of positional embeddings, leading to increased difficulty in recognizing spatial positions.

Different encoders specialize in different dimensions. For instance, OpenCLIP demonstrates superior spatial awareness, while SigLIP performs better on complex tasks such as counting and relationship recognition. These differences may stem from variations in encoder architecture and training data.

Mixed encoders underperform in geometric tasks. Contrary to real-world scenarios where combining encoders often yields better results [\(Tong et al.,](#page-10-6) [2024a;](#page-10-6) [Yang et al.,](#page-10-15) [2024\)](#page-10-15), mixed visual

Encoder class	Resolution	Avg.	Easy						Hard					
			Ext.	Cnt.		Siz. Loc. Ref. Rel.				Ext. Cnt.		Siz. Loc. Ref. Rel.

Table 2: Performance comparison of LLaVA-1.5-7B with different visual encoders (%). Best scores are in bold.

Model						Average VQA^{V2} GQA VizWiz SQA TextVQA POPE MMB SEED ¹ MMVet				
LLaVA-1.5-7B	62.7	79.2	62.7	47.0	-68.9	57.6	86.1	66.2	66.9	29.7
LLaVA-1.5-GeP-7B	63.5	78.8	63.0	52.9	70.1	58.1	86.2	64.9	67.8	29.7

Table 3: Performance comparison of LLaVA-1.5-7B and LLaVA-1.5-GeP-7B on various downstream tasks (%).

encoders fail to achieve a better result compared to their individual components. This could be due to increased noise from multiple encoders and the larger number of image tokens, which degrade positional recognition. Interestingly, the performance gap between mixed and single encoders narrows on harder tasks, suggesting that the added noise is more detrimental in simpler scenarios.

4.4 Additional Analysis

To explore the broader impact of geometric perception on downstream tasks, we use our dataset to train a new model, LLaVA-GeP, based on the LLaVA-1.5-7B architecture.

Specifically, we constructed a new training dataset using the same data pipeline as GePBench. In addition to figures and questions, we generate captions for the figures as multimodal pretraining data with the help of LLMs. The multiple-choice questions are directly utilized as instruction-tuning data. From this dataset, 300K samples are randomly selected and mixed with the original LLaVA training data for pretraining and instruction tuning, respectively. After the two-stage training process, the resulting model is evaluated on diverse real-world tasks, including VQAv2 [\(Goyal](#page-9-10) [et al.,](#page-9-10) [2019\)](#page-9-10), GQA [\(Hudson and Manning,](#page-9-2) [2019\)](#page-9-2), VizWiz [\(Gurari et al.,](#page-9-17) [2018\)](#page-9-17), ScienceQA-Image [\(Lu et al.,](#page-10-1) [2022\)](#page-10-1), TextVQA [\(Singh et al.,](#page-10-2) [2019\)](#page-10-2), POPE [\(Li et al.,](#page-9-18) [2023c\)](#page-9-18), MMBench [\(Liu et al.,](#page-9-3) [2024c\)](#page-9-3), SeedBench-Image [\(Li et al.,](#page-9-11) [2023a\)](#page-9-11) and MM-Vet [\(Yu et al.,](#page-10-16) [2024\)](#page-10-16).

The results, presented in Table [3,](#page-7-1) show general improvements across the evaluated tasks, with an average performance boost of 0.8% on 9 real-world benchmarks. Notably, tasks demanding spatial awareness, relationship understanding and scientific diagram comprehension, such as SeedBench and ScienceQA, exhibit considerable gains. A closer analysis of SeedBench results reveals that most improvements are concentrated in categories of instance interaction, counting, and spatial localization. These findings suggest that training on geometric perception data enhances the model's ability to discriminate relationships and understand spatial configurations, which translates effectively to real-world scenarios.

Interestingly, the improvement in VizWiz was primarily attributed to better handling of unanswerable questions, where mismatches between images and questions occur. This suggests that geometric perception contributes to the model's robustness in visual understanding. Collectively, these findings underscore the foundational role of geometric perception in enabling diverse downstream applications, highlighting its value in advancing multimodal learning.

5 Conclusion

In this paper, we introduce GePBench, a large-scale benchmark dataset specifically designed to evaluate geometric perception in MLLMs. Extensive experiments highlight substantial room for improvement, as even state-of-the-art models fail to achieve satisfactory results. Our analysis of visual encoders provides insights into structural design. Additionally, we demonstrate that enhancing geometric perception contributes to improved performance on a variety of downstream tasks, underscoring its foundational importance.

Limitations

Our work has two primary limitations. First, while we evaluate up to 21 representative MLLMs, including both closed-source and open-source models, there may be other models deserving analysis. Second, although our evaluation dataset comprises 250K multiple-choice questions, its size could be further expanded to enhance robustness and provide more comprehensive evaluation results.
