ABSTRACT: We construct explicit models that solve the axion quality problem originating from quantum gravitational effects. The general strategy we employ is to supplement the Standard Model and its grand unified extensions by an anomaly-free axial $U(1)_a$ symmetry that is gauged. We show that for several choices of the gauge quantum numbers of the fermions, this setup leads to an accidental $U(1)$ symmetry with a QCD anomaly which is identified as the Peccei-Quinn (PQ) symmetry that solves the strong CP problem. The $U(1)_a$ gauge symmetry controls the amount of explicit PQ symmetry violation induced by quantum gravity, resulting in a high quality axion. We present two classes of models employing this strategy. In the first class (models I and II), the axial $U(1)_a$ gauge symmetry acts on vector-like quarks leading to an accidental KSVZ-type axion. The second class (model III) is based on $SO(10)$ grand unified theory extended by a gauged $U(1)_a$ symmetry that leads to a hybrid KSVZ–DFSZ type axion. The couplings of the axion to the electron and the nucleon are found to be distinct in this class of hybrid models from those in the KSVZ and DFSZ models, which can be used to test these models. Interestingly, all models presented here have domain wall number of one, which is free of cosmological problems that typically arise in axion models.

1 Introduction

Despite its many successes, the Standard Model (SM) of particle physics is plagued by an uncontrolled amount of CP violation in the strong interaction sector arising from non-perturbative QCD effects [1–4]. This CP violation can be characterized by a new interaction Lagrangian given by $(g_s^2/32\pi^2)\bar{\theta}G_{\mu\nu}^a\tilde{G}^{a,\mu\nu}$, where g_s is the strong coupling constant, $G_{\mu\nu}^a$ is the gluon field strength tensor, $\tilde{G}^{a,\mu\nu}$ is its dual and $\bar{\theta}$ is a dimensionless coupling. In presence of this interaction, which is also parity-violating, the neutron would acquire an electric dipole moment (EDM) d_n , of order $d_n \sim (\bar{\theta} \times 10^{-16})$ e-cm [5]. The current experimental limit on neutron EDM, $d_n \leq 1.1 \times 10^{-26}$ e-cm [6], implies that $\bar{\theta} \leq 10^{-10}$. A lack of understanding of the extreme smallness of this dimensionless parameter is known as the strong CP problem. Invoking CP as an approximate symmetry to explain its smallness does not appear to be natural, since the analogous CP violating parameter in the weak interaction sector, the CKM phase δ , is of order unity.

The most widely discussed solution to the strong CP problem is the Peccei-Quinn mechanism [7], where one postulates the existence of a light pseudoscalar boson, the axion, $a(x)$, which arises as the pseudo-Nambu-Goldstone boson associated with the spontaneous breaking of a global $U(1)_{\text{PQ}}$ symmetry [8, 9]. This global $U(1)_{\text{PQ}}$ symmetry is also broken explicitly by a QCD anomaly, which induces a coupling of the axion to the gluon fields given by $(g_s^2/32\pi^2)\left(\frac{a(x)}{f_a}\right)G_{\mu\nu}^a\tilde{G}^{a,\mu\nu}$, where f_a , the axion decay constant, is the vacuum expectation value (VEV) of a scalar field that spontaneously breaks the PQ symmetry. The axion develops a potential, also through the QCD anomaly, which appears as an even function of the combination $(\bar{\theta} + \frac{a}{f_a})$. Minimizing this potential leads to the condition $\frac{a}{f_a} + \bar{\theta} = 0$, which dynamically relaxes $\bar{\theta}$ parameter to zero and thus solves the strong CP problem.

A prototypical axion model has the following effective Lagrangian:

$$\mathcal{L}^{\text{eff}} = \frac{g_s^2}{32\pi^2} \frac{a(x)}{f_a} G_{\mu\nu}^a \tilde{G}^{a,\mu\nu} - \lambda(|\Phi|^2 - f_a^2/2)^2 - \Lambda^4 \cos\left(\frac{Na(x)}{f_a}\right), \quad (1.1)$$

where Φ is a complex scalar field acquiring a vacuum expectation value f_a , and parametrized as $\Phi = (\rho + f_a)/\sqrt{2} e^{ia(x)/f_a}$, where $\Lambda \sim 200$ MeV is the QCD scale. The last term in Eq. (1.1) arises from non-perturbative QCD effects which break the $U(1)_{\text{PQ}}$ symmetry explicitly. Here N is an integer greater than or equal to 1 determined by the QCD anomaly coefficient. The explicit QCD breaking term of $U(1)_{\text{PQ}}$ still preserves a Z_N symmetry, under which $a(x) \rightarrow a(x) + 2\pi f_a m/N$ ($m = 0, 1, \dots, N-1$). This unbroken discrete symmetry gives rise to domain walls, which can modify the evolution of the universe drastically [10], an issue which we shall return to later. Minimizing the potential for the axion field given in Eq. (1.1) leads to solution $a/f_a = 0$. In writing Eq. (1.1) we have made use of a shift symmetry, $a(x) \rightarrow a(x) + f_a \bar{\theta}$, present in these models and absorbed the $\bar{\theta}$ term into the axion field.

Being a pseudo-Goldstone boson, the coupling of the axion to fermions are derivative in nature, given as

$$\mathcal{L}_{a\bar{f}f} = \frac{\partial_\mu a}{2f_a} (C_{af} \bar{f}_i \gamma^\mu \gamma_5 f_i) . \quad (1.2)$$

Here C_{af} are model-dependent coefficients which are crucial for experimental detection of the axion. Since the axion is an ultralight particle, if f_a is of order of the weak scale, it would have been produced in many laboratory experiments, such as kaon decay $K^+ \rightarrow \pi^+ + a$, as well as in astrophysical settings such as cooling of stars, leading to visible signals. The absence of any such signal rules out weak scale axion models [8, 9]. This has led to the construction of two classes of *invisible axion* models: (i) the Dine-Fishler-Srednicki-Zhinitzky (DFSZ) model [11, 12], where the SM fermions are charged under a global $U(1)_{\text{PQ}}$ symmetry which has a QCD anomaly, and where fermion mass generation is realized through a second Higgs doublet, and (ii) the Kim-Shifman-Vainshtein-Zakharov (KSVZ) model [13, 14] which introduces new vector-like quarks carrying $U(1)_{\text{PQ}}$ charges, with the SM fermions being neutral under the PQ symmetry. In both cases the $U(1)_{\text{PQ}}$ breaking scale is in the range $f_a = (10^9 - 10^{12})$ GeV, making the interactions of axion with matter very feeble. These limits on f_a are primarily derived from stellar cooling, supernova 1987A observations, as well as the cosmological mass density of the universe (for recent reviews see Ref. [15–17]).

The high scale of invisible axion models comes with a price. These models suffer from the so-called axion quality problem caused by quantum gravitational effects [18–21]. All global symmetries of nature are believed to be broken by non-perturbative gravity effects such as black holes or worm holes. Such breakings should also apply to the $U(1)_{\text{PQ}}$ symmetry. These breaking effects may be parameterized by higher dimensional operators suppressed by appropriate powers of the Planck scale, M_{Pl} . If an operator of the type $|\Phi|^4 \Phi / M_{\text{Pl}}$, induced by quantum gravity, is added to the scalar potential of Eq. (1.1), the $\bar{\theta} = 0$ solution would be destabilized, unless the coefficient of this operator is less than about 10^{-50} . The required tuning of parameters here is much stronger than the one needed for the original $\bar{\theta}$. This in essence is the axion quality problem [18–21].

There have been various attempts in the literature to address the axion quality problem. One idea that has been suggested is to realize $U(1)_{\text{PQ}}$ as an accidental symmetry in presence of a gauged $U(1)$ symmetry [20, 22, 23]. Such an accidental axion may also arise from non-Abelian gauge symmetries [24, 25]. A second mechanism assumes that the axion is a composite particle, in which case the quantum gravity-induced operators may have high enough power suppression factors [26–34]. Discrete gauge symmetries [35] have been proposed that act as accidental $U(1)_{\text{PQ}}$ up to very high orders in non-renormalizable operators. Mirror universe models [36, 37], multiple replication of the SM sector [38, 39], and extra dimensional [40–42] and string theoretic constructions [43] have also been proposed to address the axion quality problem. Extension of the color gauge symmetry from $SU(3)$ to $SU(N)$ has been proposed to generate new contributions to the axion mass dynamically [44], which can also help with addressing the axion quality.

The purpose of this paper is to present a class of models that provides a high quality axion. The method we develop here is based on a gauged $U(1)_a$ extension of the SM as well as a unified $SO(10)$ theory which naturally leads to an accidental $U(1)_{\text{PQ}}$ symmetry by virtue of the particle spectrum and the $U(1)_a$ charge assignment. This method is similar to the one suggested in Ref. [20], but with a slightly more economical particle spectrum, and an extension to grand unification. We present two classes of models. In

the first class (models I and II), SM is extended with a gauged $U(1)_a$ symmetry acting on a set of vector-like quarks that results in an accidental $U(1)_{\text{PQ}}$ and a KSVZ-type axion. The second class of models is based on unified $SO(10)$ symmetry appended by a gauged $U(1)_a$ that results in a hybrid DFSZ-KSVZ axion model (model III). A common feature of these models is that they all have two disjoint sectors which are connected only by higher-dimensional gravity-induced operators. At the renormalizable level these models have a $U(1)_a \times U(1)_{\text{PQ}}$ symmetry, with the $U(1)_{\text{PQ}}$ being anomalous with respect to QCD. As long as the two sectors are sufficiently separated, measured in terms of the dimensionality of the gravity-induced operators that generate interlocking couplings, a high quality axion can be realized. The gauged $U(1)_a$ symmetry protects quantum gravity corrections to the shift in $\bar{\theta}$ to sufficient degree in these models, thus ensuring a high quality axion.

The paper is organized as follows. In Sec. 2 we discuss quantitatively the axion quality problem and provide an overview of the mechanism that we adopt to solve it via gauged $U(1)_a$ symmetry. In Sec. 3 we present our first model (model I) that results in an accidental KSVZ-type axion. Four vector-like quarks with axial $U(1)_a$ charges are employed in model I. Here we also discuss the phenomenology and the cosmology of the model as well as the fermion mass generation mechanism. Sec. 4 generalizes model I into a family of models (model II), which introduces $m + 1$ vector-like quarks where $m \geq 4$. In Sec. 5 we present a unified $SO(10) \times U(1)_a$ model that leads to a high quality hybrid DFSZ-KSVZ axion model which we proposed in Ref. [23]. In Sec. 6 we provide further details of the model, including loop-induced corrections to the $\bar{\theta}$ parameter, calculation of the domain wall number, and phenomenological issues and dark matter parameter space of the hybrid axion. In Appendix A, we briefly review the Barr-Seckel model of high quality axion with which our models I and II may be compared. Here we also provide a UV completion of this class of models and discuss ways to address the cosmological domain wall issues.

2 The axion quality problem and a solution from gauged $U(1)_a$

In this section we provide a quantitative analysis of the axion quality problem and give an overview of our method to address it with a gauged $U(1)_a$ symmetry.

2.1 Axion quality problem

The explicit breaking of the global $U(1)_{\text{PQ}}$ symmetry by the QCD anomaly induces a coupling of the axion field to the gluon fields with the effective Lagrangian given as $(g_s^2/32\pi^2) \left(\frac{a(x)}{f_a} + \bar{\theta} \right) G_{\mu\nu}^a \tilde{G}^{a,\mu\nu}$. This coupling, in turn, would induce a potential for the axion field, which has been computed in chiral perturbation theory to be [8, 45]:

$$V(a) \simeq -m_\pi^2 f_\pi^2 \sqrt{1 - \frac{4m_u m_d}{(m_u + m_d)^2} \sin^2 \left(\frac{a}{2f_a} + \frac{\bar{\theta}}{2} \right)}. \quad (2.1)$$

Minimizing this potential would lead to the desired condition

$$\sin \left(\frac{a}{f_a} + \bar{\theta} \right) = 0. \quad (2.2)$$

(Here the $\bar{\theta}$ term is not absorbed into the axion field by a shift transformation $a \rightarrow a + f_a \bar{\theta}$.) Once we add to this potential higher dimensional operators induced by quantum gravity that violate the PQ symmetry, $\left(\frac{a}{f_a} + \bar{\theta}\right)$ would shift away from zero, destabilizing the axion solution to the strong CP problem.

Consider for example, the addition of a $d = 5$ term to the Higgs potential of Eq. (1.1) arising from quantum gravity:

$$V_{\text{gravity}} = \frac{\kappa}{2!3!M_{\text{Pl}}}| \Phi |^4 (e^{i\delta} \Phi + h.c.) \quad (2.3)$$

Here κ and δ are real parameters, which are presumably of order unity. The factors $2!3!$ in the denominator of Eq. (2.3) are symmetry factors for identical $(\Phi^*)^2$ and $(\Phi)^3$ fields, which we shall adopt for the quantum gravity corrections. (We also quote results when such symmetry factors are assumed to be not present.) Writing $\Phi = (\rho + f_a)/\sqrt{2} e^{ia(x)/f_a}$, Eq. (2.3) leads to a correction to the axion potential given as

$$V_{\text{gravity}}^a \simeq \frac{\kappa}{6M_{\text{Pl}}} \frac{f_a^5}{2^{5/2}} \cos\left(\frac{a}{f_a} + \delta\right). \quad (2.4)$$

Minimizing the full potential of Eq. (2.1) and Eq. (2.4) would shift the vacuum so that $\left(\frac{a}{f_a} + \bar{\theta}\right)$ now becomes (assuming this shift arising from V_{gravity} is small)

$$\left(\frac{a}{f_a} + \bar{\theta}\right) \simeq \frac{\kappa \sin \delta}{24\sqrt{2}} \frac{f_a^5}{m_\pi^2 f_\pi^2 M_{\text{Pl}}} \frac{(m_u + m_d)^2}{m_u m_d}. \quad (2.5)$$

Using $M_{\text{Pl}} = 1.22 \times 10^{19}$ GeV, $f_\pi = 93$ MeV, $m_\pi = 140$ MeV, and $m_u/m_d = 0.56$, and requiring that $\bar{\theta} \leq 10^{-10}$ leads to the constraint

$$|\kappa \sin \delta| \leq 1.6 \times (10^{-39}, 10^{-44}, 10^{-54}), \quad \text{for } f_a = (10^9, 10^{10}, 10^{12}) \text{ GeV}. \quad (2.6)$$

The required fine-tuning is even more severe than the one needed for the original strong CP parameter $\bar{\theta}$, causing the axion quality problem [18–21]. Note that in the original Weinberg-Wilczek axion model, the required tuning is very mild, with $|\kappa \sin \delta| \leq 10^{-3}$ for $f_a = 10^2$ GeV. It is the phenomenological requirement of making the axion invisible, by choosing $f_a = (10^9 - 10^{12})$ GeV, that results in the quality problem.

2.2 Mechanism for solving the axion quality problem with a gauged $U(1)_a$

The models we present have a gauged $U(1)_a$ symmetry which acts axially on fermions fields. That is, the $U(1)_a$ charges of left-chiral and right-chiral fermions are equal and opposite. In addition, the fermions and scalar fields form two separate sectors at the renormalizable level, leading to an accidental $U(1)_p \times U(1)_q$ symmetry. Each of these accidental $U(1)$ s has a QCD anomaly, but one combination must have vanishing QCD anomaly, corresponding to the gauged $U(1)_a$ symmetry. The full symmetry may then be taken as $U(1)_a \times U(1)_{\text{PQ}}$, with the second factor leading to an accidental axion.

To see more explicitly the origin of the axion field, consider the breaking of the $U(1)_a$ gauge symmetry by two SM singlet scalar fields S and T with $U(1)_a$ charges of q_S and

q_T . If the charges $q_{S,T}$ are appropriately chosen, the potential for the S and T fields at the renormalizable level may be functions of the polynomials S^*S and T^*T with no interlocking terms that are nontrivial. The quark fields also belong to two separate sectors, with one set of quarks acquiring their masses from the VEV of S , and the other from T . The renormalizable theory will then have a global symmetry $U(1)_S \times U(1)_T$ symmetry, operating on S and T sectors separately. The axion field arises as the orthogonal combination to the Nambu-Goldstone field that is eaten up by the $U(1)_a$ gauge boson. To see this, let us parametrize the S and T fields, which are assumed to have negative squared masses, as

$$T = \frac{(\rho_T + f_T)}{\sqrt{2}} e^{i\eta_T/f_T}, \quad S = \frac{(\rho_S + f_S)}{\sqrt{2}} e^{i\eta_S/f_S}. \quad (2.7)$$

Here (ρ_S, ρ_T) are the radial modes, which do not play any role in the axion identification, and may be set to zero for this purpose. f_S and f_T are the VEVs of the respective fields S and T . The Goldstone mode and the orthogonal axion mode are then found to be

$$G = \frac{(q_S f_S \eta_S + q_T f_T \eta_T)}{\sqrt{q_S^2 f_S^2 + q_T^2 f_T^2}}, \quad a = \frac{(q_T f_T \eta_S - q_S f_S \eta_T)}{\sqrt{q_S^2 f_S^2 + q_T^2 f_T^2}}. \quad (2.8)$$

Owing to the accidental $U(1)_{\text{PQ}}$ symmetry the axion field receives zero mass from the scalar potential, although the QCD anomaly would induce a potential for it as given in Eq. (2.1), and from it a small axion mass given by

$$m_a^2 \simeq \frac{f_\pi^2 m_\pi^2}{f_a^2} \frac{m_u m_d}{(m_u + m_d)^2}. \quad (2.9)$$

Higher dimensional gravity-induced operators would generate interlocking couplings involving T and S in a nontrivial way. If the charges q_S and q_T are such that these operators have high enough dimension, the axion quality can be preserved, as we show in the three models discussed in subsequent sections. As an example, consider the charges (q_S, q_T) to be co-prime integers, in which case the lowest order interlocking operator induced by gravity would be $(S)^{q_T} (T^*)^{q_S} / M_{\text{Pl}}^{q_S + q_T - 4}$. If in any given model, $(q_S + q_T) \geq 10$ can be satisfied, a high quality axion will be realized [18, 20].

3 Model I: Realizing high quality KSVZ-type axion

The first model we present is based on the gauge group $G_{SM} \times U(1)_a$, where G_{SM} is the standard model gauge group. All SM fermions and the Higgs doublet are assumed to be neutral under $U(1)_a$. We add four vector-like quarks (VLQs) which are color triplets and $SU(2)_L$ singlets carrying hypercharge y .¹ Their charge assignment is given in Table 1. It is easy to see that all gauge anomalies cancel. All linear anomalies in $U(1)_a$ vanish among

¹We find that the minimum number of VLQs needed to realize a high quality axion in this framework is 4. With only 3 such VLQs, having axial $U(1)_a$ charges of $\pm(1, 1, -2)$, loop corrections to the shift in $\bar{\theta}$ destabilize the axion solution.

New fermion	$SU(3)_c \times SU(2)_L \times U(1)_Y$	$U(1)_a$ charge q_i
$(Q_L)_{1,2,3,4}$	$(3, 1, y)$	$(1, 1, 1, -3)$
$(Q_R)_{1,2,3,4}$	$(3, 1, y)$	$-(1, 1, 1, -3)$
$(N_R)_{1,2,3}$	$(1, 1, 0)$	$(2, 4, -6)$
New scalar	$SU(3)_c \times SU(2)_L \times U(1)_Y$	$U(1)_a$ charge
T	$(1, 1, 0)$	6
S	$(1, 1, 0)$	$2/n$

Table 1: New fermions and scalars, along with their quantum numbers under the standard model as well as their respective $U(1)_a$ charges q_i in Model I. Here $n \geq 4$ is an integer.

the left-handed and the right-handed VLQs separately owing to the tracelessness property of the charges:

$$\sum_{i=1}^4 q_i(Q_L) = 0, \quad \sum_{i=1}^4 q_i(Q_R) = 0. \quad (3.1)$$

This includes anomaly coefficients $A[SU(3)_c^2 \times U(1)_a]$, $A[SU(2)_L^2 \times U(1)_a]$, $A[U(1)_Y^2 \times U(1)_a]$ and $A[(\text{gravity})^2 \times U(1)_a]$, which all vanish among the left-handed fermions and separately among the right-handed fermions. As for the anomaly coefficient $A[U(1)_Y \times U(1)_a^2]$, the axial assignment of the $U(1)_a$ charges, along with the universal hypercharge assignment y , implies that the left-handed and right-handed VLQs contribute an equal and opposite amount, leading to the cancellation of this anomaly as well. Finally, the cubic anomaly coefficient $A[(U(1)_a)^3]$ adds up to zero when the VLQ (-144) and the right-handed singlet fermion contributions N_{Ri} $(+144)$ are summed. The choice of $y = 2/3$ or $-1/3$ has the advantage that the VLQs can mix with the SM quarks through higher dimensional operators, in which case there are no cosmological problems with a stable VLQ even with post-inflationary PQ symmetry breaking.

The model has two scalar fields denoted as T and S with $U(1)_a$ charges 6 and $2/n$ respectively. Here n is an integer greater than or equal to 4. This choice is dictated by the requirement of high quality axion in presence of gravity-induced higher dimensional operators, including loop corrections that modify the Higgs potential. The Higgs potential involving the scalar fields S and T is given by

$$V(T, S) = -\mu_T^2 T^* T - \mu_S^2 S^* S + \lambda_S (S^* S)^2 + \lambda_T (T^* T)^2 + \lambda_{TS} (T^* T) (S^* S). \quad (3.2)$$

As noted in Sec. 2, the potential of Eq. (3.2) has no interlocking terms, at the renormalizable level, connecting the T and S fields nontrivially.

Bare mass terms for the vector-like quark fields and the singlet fermion fields N_{iR} in the model are not allowed owing to the chiral nature of their $U(1)_a$ charges. Their masses are generated through Yukawa couplings given by

$$\begin{aligned} -\mathcal{L}_{\text{Yuk}} = & Y_{44}^{(Q)} \bar{Q}_{4L} Q_{4R} T^* + \sum_{a,b=1}^3 Y_{ab}^{(Q)} \bar{Q}_{aL} Q_{bR} \frac{S^n}{n! M_*^{n-1}} \\ & + Y_{12}^{(N)} N_{1R} N_{2R} T^* + \frac{Y_{33}^{(N)}}{2} N_{3R} N_{3R} \frac{T^2}{2! M_*} + h.c. \end{aligned} \quad (3.3)$$

Here M_* is a new scale, which should not be much larger than the PQ breaking scale, so that the VLQs acquire masses above a TeV to be compatible with LHC search limits. For example, with $n = 4$, the choice of $f_S = 5 \times 10^{10}$ GeV would set an upper limit of $M_* \leq 6 \times 10^{12}$ GeV, so that the VLQ masses are greater than 1.2 TeV, where we have assumed that the Yukawa coefficients $Y_{ab}^{(Q)}$ are of order one.

Note that this model has an accidental $U(1) \times U(1)$ symmetry. The $U(1)$ charges of various fields may be assigned as follows. Under the first $U(1)$, (Q_{4L}, Q_{4R}) have charges $(-3, +3)$, $(N_{1R}, N_{2R}, N_{3R}) = (2, 4, -6)$ and $T = +6$ while all other fields have zero charge. Under the second $U(1)$, $(Q_{aL}, Q_{aR}) = (1, -1)$ for $a = 1, 2, 3$, and $S = 2/n$ with other fields being neutral. Thus, $(Q_{4L}, Q_{4R}, N_{(1,2,3)R}, T)$ form one sector of the theory while (Q_{aL}, Q_{aR}, S) form a second decoupled sector. Both of these $U(1)$ s have QCD anomalies, but one combination of the two is the gauged $U(1)_a$, which has no anomalies. An orthogonal combination to $U(1)_a$ is a global symmetry which has a QCD anomaly and serves as the $U(1)_{\text{PQ}}$ symmetry. The gravity-induced couplings, to be discussed in Sec. 3.2, would only respect the gauged $U(1)_a$ symmetry and would violate the global $U(1)_{\text{PQ}}$ symmetry.

3.1 Calculation of $aG\tilde{G}$ coupling in Model I

With negative squared masses for the T and S fields, both will acquire real VEVs, denoted as f_T and f_S , as parametrized in Eq. (2.7). The masses of the vector-like fermions and the singlet fermions are given by

$$\begin{aligned} M_{Q_4} &= \frac{Y_{44}^{(Q)} f_T}{\sqrt{2}}, & M_{Q_a} &= \frac{Y_a^{(Q)} f_S^n}{2^{n/2} n! M_*^{n-1}} \quad (a = 1, 2, 3) \\ M_{N_1} = M_{N_2} &= \frac{Y_{12}^{(N)} f_T}{\sqrt{2}}, & M_{N_3} &= \frac{Y_{33}^{(N)} f_T^2}{4M_*}. \end{aligned} \quad (3.4)$$

Here $|Y_a^{(Q)}|^2$ are the eigenvalues of the 3×3 matrix $Y^{(Q)\dagger} Y^{(Q)}$. With M_* assumed to be not too much larger than the VEVs (f_T, f_S), all vector-like fermions acquire masses of order (f_T, f_S) .

Using the exponential parametrization for (T, S) fields as in Eq. (2.7), we can identify the would-be Goldstone field G eaten up by the $U(1)_a$ gauge boson, and the orthogonal massless field identified as the axion a as:

$$G = \frac{(\frac{2}{n} f_S \eta_S + 6 f_T \eta_T)}{\sqrt{(6 f_T)^2 + (\frac{2}{n} f_S)^2}}, \quad a = \frac{(6 f_T \eta_S - \frac{2}{n} f_S \eta_T)}{\sqrt{(6 f_T)^2 + (\frac{2}{n} f_S)^2}}. \quad (3.5)$$

The Lagrangian involving the quarks and the axion field can now be readily obtained. We find it to be

$$-\mathcal{L}_{\text{Yuk}}(a) = ia \left[\bar{Q}_4 \gamma_5 Q_4 \frac{f_S}{f_T} \frac{M_{Q_4}}{\sqrt{9 f_T^2 n^2 + f_S^2}} + \sum_{a=1}^3 \bar{Q}_a \gamma_5 Q_a \frac{3 n^2 f_T}{f_S} \frac{M_{Q_a}}{\sqrt{9 f_T^2 n^2 + f_S^2}} \right]. \quad (3.6)$$

Summing over the four quarks in computing $aG\tilde{G}$ coefficient, one obtains

$$\frac{1}{f_a} = \frac{f_S}{f_T} \frac{1}{\sqrt{9f_T^2 n^2 + f_S^2}} + (3 \times 3n^2) \frac{f_T}{f_S} \frac{1}{\sqrt{9f_T^2 n^2 + f_S^2}}, \quad (3.7)$$

which simplifies to

$$f_a = \frac{f_T f_S}{\sqrt{9f_T^2 n^2 + f_S^2}}. \quad (3.8)$$

It appears in the axion-gluon interaction Lagrangian defined as

$$\mathcal{L}_{aGG} = \frac{g_s^2}{32\pi^2} \frac{a}{f_a} G_{\mu\nu}^a \tilde{G}^{a,\mu\nu}. \quad (3.9)$$

3.2 Gravity effects and axion quality in Model I

Since gravity effects only respect the gauge symmetry, and not the global $U(1)_{\text{PQ}}$ symmetry, one should ensure that these effects, which are parametrized as higher dimensional operators with appropriate powers of inverse Planck mass, do not destabilize the PQ solution to the strong CP problem. The separation of the fields into two disjoint sectors, $(Q_{4L}, Q_{4R}, N_{(1,2,3)R}, T)$ and (Q_{aL}, Q_{aR}, S) is spoiled by gravity-induced corrections. In this section, we investigate this issue for model I. There are several sources of $U(1)_{\text{PQ}}$ symmetry violation. The first source we analyze is the contribution to the scalar potential of the model, with the leading term given by

$$V_{\text{gravity}} = \frac{\kappa e^{i\delta} S^{3n} T^*}{(3n)! M_{\text{Pl}}^{3n-3}} + h.c. \quad (3.10)$$

The potential involving the axion field resulting from here is

$$V_{\text{gravity}}^a = \frac{\kappa}{(3n)! 2^{(3n-1)/2}} \frac{f_S^{3n} f_T}{M_{\text{Pl}}^{3n-3}} \cos\left(\frac{a}{f_a} + \delta\right) \quad (3.11)$$

Minimizing this potential, along with the QCD-induced axion potential given in Eq. (2.1), will lead to a shifted value of $\bar{\theta}$, which, in the approximation that the shift is small, is given as

$$\bar{\theta} \simeq \frac{\kappa \sin \delta}{(3n)! 2^{(3n-1)/2}} \frac{f_S^{3n} f_T}{M_{\text{Pl}}^{3n-3} m_\pi^2 f_\pi^2} \frac{(m_u + m_d)^2}{m_u m_d}. \quad (3.12)$$

Choosing $f_S = f_T = f_a \sqrt{1 + 9n^2}$, we find, with $\kappa \sin \delta = 1$,

$$|\bar{\theta}| \simeq \begin{cases} 2.7 \times 10^{-25} & (n = 4, f_a = 5 \times 10^{10} \text{ GeV}) \\ 9.6 \times 10^{-29} & (n = 5, f_a = 10^{12} \text{ GeV}) \end{cases}. \quad (3.13)$$

This shows that the axion is of high quality, including the gravity-induced higher dimensional operator of Eq. (3.10). If $n = 3$ is chosen, the axion will not be of high quality, since $|\bar{\theta}| \simeq 0.48$ will result for $f_a = 5 \times 10^{10}$ GeV, a value preferred by axion being the entire DM component of the universe. The choice of $n = 3$ is also disfavored by loop-induced contributions to $\bar{\theta}$, which we now discuss.

Figure 1: A three-loop diagram inducing a purely scalar operator $S^{3n} T^*$ that affects the axion quality. The relevant operators inducing this diagram are given in Eq. (3.14) and Eq. (3.3).

There are four types of higher dimensional operators involving the VLQs that can destabilize the axion quality through loop diagrams.² They are given by

$$\begin{aligned} \mathcal{L}_{\text{gravity}}^{\text{Yuk}} = & \kappa_{ab} \frac{(\overline{Q}_{aL} Q_{bR})^3 T}{M_{\text{Pl}}^6} + \kappa_{44} \frac{\overline{Q}_{4L} Q_{4R} (S^*)^{3n}}{(3n)! M_{\text{Pl}}^{3n-1}} \\ & + \kappa_{a4} \frac{\overline{Q}_{aL} Q_{4R} (S^*)^n}{n! M_{\text{Pl}}^{n-1}} + \kappa_{4a} \frac{\overline{Q}_{4L} Q_{aR} (S^*)^n}{n! M_{\text{Pl}}^{n-1}} + h.c. \end{aligned} \quad (3.14)$$

The first operator in Eq. (3.14), when combined with the second term of Eq. (3.3), would induce a purely scalar operator $S^{3n} T^*$ through a three-loop diagram shown in Fig. 1. The induced Lagrangian can be estimated to be

$$V_{\text{gravity}} \sim \kappa_{ab} \left(\frac{\text{Tr}(Y^{(Q)})}{16\pi^2} \right)^3 \frac{S^{3n} T^*}{(3n)! M_*^{3n-3}} \left(\frac{M_*}{M_{\text{Pl}}} \right)^6 + h.c. \quad (3.15)$$

Each loop has a naive quadratic divergence, which is cut-off by the scale M_* . Comparing Eq. (3.17) with Eq. (3.10) we see that these loop-induced corrections can be more important, with some of the M_{Pl} factors replaced by M_* in the denominator. However, these contributions are safe as can be seen by setting $n = 4$, $M_* = 1 \times 10^{12}$ GeV, $\text{Tr}(Y^{(Q)}) = 0.1$, $\kappa_{ab} = 1$, in which case $\bar{\theta} \sim 1.2 \times 10^{-13}$. For $n = 5$ or larger, these corrections are even smaller. For example, for $n = 5$, we find the induced $\bar{\theta}$ to be $\bar{\theta} \sim 1.2 \times 10^{-16}$ with the other parameters being the same as quoted above.

In Fig. 2 we have shown a one-loop diagram that induces the operator $S^{3n} T^*$ by utilizing the last two terms of Eq. (3.14), along with the first term of Eq. (3.3). The

²We thank Vasja Susic for emphasizing to us the importance of loop diagrams for axion quality.

Figure 2: A one-loop diagram inducing a purely scalar operator that breaks the PQ symmetry. This diagram uses the operators given in Eq. (3.14).

induced potential arising from this diagram can be estimated to be

$$V_{\text{gravity}} \sim \frac{Y_{44}^{(Q)}}{16\pi^2} \left(\kappa_{a4}^* Y_{ab}^{(Q)} \kappa_{4b}^* \right) \frac{S^{3n} T^*}{(3n)! M_{\text{Pl}}^{3n-3}} \left(\frac{M_{\text{Pl}}}{M_*} \right)^{n-1}. \quad (3.16)$$

The associated shift in $\bar{\theta}$ is within acceptable limits for a range of parameters. For example, with $n = 4$, $f_T = f_S$, $f_a = 5 \times 10^{10}$ GeV, $M_* = 4 \times 10^{12}$ GeV, $Y^{(Q)} = Y_{44}^{(Q)} = 0.05$, one would have $\bar{\theta} \sim 10^{-10}$. Other acceptable choices of parameters are also possible. If $n = 5$ is chosen, with the other parameters as quoted above, $\bar{\theta} \sim 10^{-28}$, well below the required value for a high quality axion.³

As for the κ_{44} term in Eq. (3.14), it would induce a sub-dominant shift in $\bar{\theta}$ owing to the higher power of M_{Pl} in the denominator of this term. The effective scalar operator that arises from a one-loop diagram analogous to Fig. 2 is given by

$$V_{\text{gravity}} \sim \frac{Y_{44}^{(Q)}}{16\pi^2} \frac{\kappa_{44} S^{3n} T^*}{(3n)! M_{\text{Pl}}^{3n-3}} \left(\frac{M_*}{M_{\text{Pl}}} \right)^2 + h.c. \quad (3.17)$$

Comparing Eq. (3.17) with Eq. (3.10) one finds that this contribution is suppressed by a loop factor as well as an additional factor $(M_*/M_{\text{Pl}})^2 \ll 1$. Thus, once the condition of Eq. (3.10) is satisfied, so is the condition of Eq. (3.17).

In the gravity-induced operators we have assumed the presence of a $n!$ factor in the denominator for n identical particles, in analogy with quantum field theory calculations. If such factors are not present, while the $n = 4$ case would lose its high-quality axion, any larger value of $n \geq 5$ will still preserve its high quality.

³If only three VLQs with axial charges $\pm(1, 1, -2)$ are used, an effective operator $(\bar{Q}_{aL} Q_{bR})^2 T / M_{\text{Pl}}^3$ would be induced by gravity. In this case, a two-loop diagram analogous to Fig. 1 would induce a $\bar{\theta}$ that exceeds the allowed range. Thus we see that the minimum number of VLQs needed in this setup is 4.

3.3 Axion coupling to fermions and photon in Model I

By construction of the model, model I yields a KSVZ-type axion. As such, the axion does not couple to the SM fermions at tree-level. Axion couplings to the nucleon arise from the $aG\tilde{G}$ interactions which are universal to all models. As for the $a\gamma\gamma$ coupling, due to the non-zero hypercharge y of the VLQs of the model, there is a non-zero contribution. The $a\gamma\gamma$ coupling is usually written as consisting of two parts: one from the triangle graph involving the charged fermions of the theory which have direct couplings to axion, and a second one from the $a - \pi^0$ mixing, which has the same value of -1.92 in all axion models [15]. In model I, we find for the model-dependent ratio of the axion coupling to the photon versus the gluon, parametrized by E/N as $E/N = 8/3$ for $y = 2/3$ and $E/N = 2/3$ if $y = -1/3$ is chosen. If $y = 0$ is chosen, there is a small three-loop contribution to $g_{a\gamma\gamma}$, with the first loop connecting a to gluons via the Q fermions and the gluons in turn connecting to SM quarks which then give rise to two photons. The net $g_{a\rightarrow\gamma\gamma}/g_{ag} \sim -1.92 + E/N$. The value of $E/N = 8/3$ is identical to the value obtained in the DFSZ axion model [15].

The aee coupling which arises from $a\gamma\gamma$ couplings at the loop level is small. As far as the aNN coupling is concerned, the values are: $g_{app} = -0.47$ and $g_{ann} = -0.02$ as in the KSVZ model since there are no tree-level quark couplings to the axion and this comes only from the aGG coupling [15]. These properties of the model, while difficult to disentangle from the KSVZ model, can potentially be used as tests of the model.

In the case that the hypercharges y of the VLQs is chosen so that $y = 2/3$ or $y = -1/3$, operators of the type $\bar{Q}_{aL}u_R S^{n/2}/M_{\text{Pl}}^{n/2-1}$ or $\bar{Q}_{aL}d_R S^{n/2}/M_{\text{Pl}}^{n/2-1}$ (for even n), can arise from gravity that can lead to mixing of the VLQs with the SM quarks (u, d), and thereby their decays. This would evade cosmological constraints for a stable vector-like quark. Such operators do not affect the axion quality, as the SM sector can be grouped together with the scalar sector S .

3.4 Domain wall number in Model I

Let us now comment on the question of domain wall number and potential cosmological problem with them in this model [10]. Since the global PQ symmetry is not uniquely defined in the theory – any linear combination of a PQ symmetry and the gauged $U(1)_a$ symmetry also is a valid PQ symmetry – calculation of the domain wall number N_{DW} requires more care. We follow the procedure developed in Ref. [46] to determine N_{DW} . Once the axion field a is identified as in Eq. (3.5) in terms of the pseudoscalar fields contained in the original fields, one can write in general

$$a = \sum_i c_i \eta_i . \quad (3.18)$$

The coefficients c_i for model I can be read off from Eq. (3.5). We have $c_S = 3f_T n / \sqrt{9f_T^2 n^2 + f_S^2}$, $c_T = -f_S / \sqrt{9f_T^2 n^2 + f_S^2}$, with the decay constant f_a given as in Eq. (3.8).

The domain wall number can be computed from the formula [46]

$$N_{\text{DW}} = \text{minimum integer} \left\{ \frac{1}{f_a} \sum_i n_i c_i f_i , \quad n_i \in \mathcal{Z} \right\} . \quad (3.19)$$

Figure 3: A UV-complete diagram to induce the VLQ masses in Model I. Here we have adopted $n = 5$. The primes quarks have vectorial charges under $U(1)_a$, allowing for their bare masses, which are indicated as dots in the figure.

Using the values of c_S , c_T , and f_a for the model, we obtain

$$N_{\text{DW}} = \text{minimum integer}(3n_1n - n_2) . \quad (3.20)$$

One should choose the integers n_1 and n_2 so as to find the minimum value for N_{DW} . Taking $n_1 = 1$, $n_2 = 3n - 1$, we find $N_{\text{DW}} = 1$. It is interesting that even though the model has 4 VLQs, the domain wall number turns out to be 1. This is a consequence of the interplay between the $U(1)_{\text{PQ}}$ and the gauged $U(1)_a$. Domain wall number of one does not cause any problem with early universe cosmology, since it is unstable and dissipates well above the BBN temperature. It does contribute to the relic density of the axion, which we shall take into account in constraining the axion mass and f_a .

3.5 Axion as dark matter in Model I

In a post-inflationary PQ breaking scenario, which is what we adopt, the axion can be the entire dark matter(DM) component of the universe. The needed value of the axion mass and decay constant has been investigated numerically [47], which finds a range

$$f_a = (4.6 - 7.2) \times 10^{10} \text{ GeV} \quad (3.21)$$

for the net contribution to the axion relic density to be consistent with observations corresponding to the case of $N_{\text{DW}} = 1$. These contributions include three sources of axion production: via vacuum misalignment during the QCD phase transition, axions from global string decays, and axions from the decay of the domain wall. The axion mass corresponding to the range of f_a quoted in Eq. (5.14) is (see Eq. (2.9))

$$m_a = (80 - 130) \mu eV . \quad (3.22)$$

A more recent simulation [48] finds a slightly wider range of the axion mass, $m_a = (40 - 300) \mu eV$. Since the quality of the axion is quite good within the model, both ranges of the axion mass are fully consistent, and the model can easily accommodate the entire DM in the form of axion.

3.6 A UV complete model for the mass scale M_*

The Yukawa couplings of Eq. (3.3) make use of higher dimensional operators suppressed by powers of a scale M_* to induce the masses of the VLQs with $U(1)_a$ charges ± 1 . If M_* is

identified as M_{PL} , with the integer n obeying $n \geq 4$ to realize a high quality axion, these VLQ masses would be well below a TeV which would conflict direct experimental limits. This implies that some form of new physics should lie below M_{Pl} that induces the VLQ masses. Here we show an example, which would provide a UV completion of the model.

One way of UV-completing the model is presented in Fig. 3. This corresponds to the case of $n = 5$, so that the effective operator involving the Q_a fields is $\overline{Q}_{aL} Q_{bR} S^5 / M_*^4$. Here M_* may be identified as the (common) mass of the VLQs labeled Q' which have vectorial $U(1)_a$ charges. These new fermions, with vectorial $U(1)_a$ assignment, will not modify the anomaly cancellation conditions for the $U(1)_a$ sector. Specifically, for $n = 5$ we take the charges of these Q' quarks to be

$$Q'_1 : -\frac{3}{5}, \quad Q'_2 : -\frac{1}{5}, \quad Q'_3 : \frac{1}{5}, \quad Q'_4 : -\frac{3}{5}, \quad \text{and} \quad Q_{aL} : 1, \quad Q_{bR} : -1, \quad S : \frac{2}{5}. \quad (3.23)$$

With these charges, the following renormalizable Yukawa couplings can be written down:

$$\begin{aligned} \mathcal{L}_{\text{Yuk}}^{\text{UV}} = & \overline{Q}_{bL} Q'_{4R} S + \overline{Q}'_{4L} Q'_{3R} S + \overline{Q}'_{3L} Q'_{2R} S + \overline{Q}'_{2L} Q'_{1R} S \\ & + \overline{Q}'_{1L} Q_{aR} S + \sum_{\alpha=1}^4 M_\alpha \overline{Q}'_{\alpha L} Q'_{\alpha R} + h.c. \end{aligned} \quad (3.24)$$

We see that the effective operator $\overline{Q}_{bL} Q_{aR} S^4$ will be induced, once the Q' quarks are integrated out.

Once the UV-completion of the model is achieved, it is important to check if the new fields introduced can have an effect on the axion quality. With the charges of the Q' fields as given in Eq. (3.23), one can consider the fields (Q_{aL}, Q_{aR}, S, Q') to belong to one sector which preserves the global $U(1)_{\text{PQ}}$ symmetry. Operators of the type $\overline{Q}'_{1L} Q_{4R} (S^*)^6 / M_{\text{Pl}}^5$ will be induced by gravity, but such couplings do not upset the axion quality. These couplings have to be combined with other such couplings, which would make the resulting shift in $\overline{\theta}$ well within the allowed range.

As for the N_3 mass term in Eq. (3.3), the corresponding M_* may actually be M_{Pl} , in which case $M_{N_3} \sim f_a^2 / M_{\text{Pl}} \sim \text{TeV}$. Alternatively, this mass term can arise by integrating out a singlet fermion N_0 with zero $U(1)_a$ charge.

4 Model II: A family of models generalizing Model I

There is a simple generalization of Model I to a family of models. Here the number of vector-like quarks is chosen to be $m + 1$ with m of them carrying $U(1)_a$ charge of $+1$ (for left-handed sector) and -1 (for right-handed sector) while the $(m + 1)^{\text{th}}$ quark has charge $\mp m$. This assignment, shown in Table 2, is anomaly-free, including contributions from three singlet fermions $(N_R)_{1,2,3}$ with their charges as indicated. This provides a family of models, which is anomaly-free for arbitrary integer values of m . As in Model I, two SM singlet scalars, T and S are introduced with $U(1)_a$ charges of $2m$ and $2/n$ respectively. Here n is a positive integer with its allowed values for axion quality depending on the integer m . The choice $m = 3$ corresponds to Model I.

New fermion	$SU(3)_c \times SU(2)_L \times U(1)_Y$	$U(1)_a$ charge
$(Q_L)_{1,2,3,\dots,m,m+1}$	$(3, 1, y)$	$(1, 1, 1, \dots, 1, -m)$
$(Q_R)_{1,2,3,\dots,m,m+1}$	$(3, 1, y)$	$-(1, 1, 1, \dots, 1, -m)$
$(N_R)_{1,2,3}$	$(1, 1, 0)$	$(-1 + m, 1 + m, -2m)$
New scalar	$SU(3)_c \times SU(2)_L \times U(1)_Y$	$U(1)_a$ charge
T	$(1, 1, 0)$	$2m$
S	$(1, 1, 0)$	$2/n$

Table 2: New fermions and scalars along with their transformation under the standard model and their respective $U(1)_a$ charges in Model II. Here $m \geq 3$ and n are positive integers. If $m = 3$ is chosen, this model reduces to Model I with charges given in Table 1. The allowed value of n varies, and depends on the value of m chosen.

The explicit calculations for the case of $m + 1$ quark fields follow along the lines shown for Model I ($m = 3$). The Yukawa Lagrangian in this case is given by

$$-\mathcal{L}_{\text{Yuk}} = Y_{m+1} \bar{Q}_{m+1,L} Q_{m+1,R} T^* + \sum_{i=1}^m Y_i \bar{Q}_{iL} Q_{iR} \frac{S^n}{(M^*)^{(n-1)}} + h.c. \quad (4.1)$$

The Goldstone field eaten up by the $U(1)_a$ gauge boson and the orthogonal and axion field are given by

$$G = \frac{(\frac{2}{n} f_S \eta_S + 2m f_T \eta_T)}{\sqrt{(2m f_T)^2 + (\frac{2}{n} f_S)^2}}, \quad a = \frac{(2m f_T \eta_S - \frac{2}{n} f_S \eta_T)}{\sqrt{(2m f_T)^2 + (\frac{2}{n} f_S)^2}}. \quad (4.2)$$

The Yukawa Lagrangian involving the axion and the VLQs is now

$$-\mathcal{L}_{\text{Yuk}}(a) = ia \left[\bar{Q}_{m+1} \gamma_5 Q_{m+1} \frac{f_S}{f_T} \frac{M_{Q_{m+1}}}{\sqrt{f_T^2 m^2 n^2 + f_S^2}} + \sum_{i=1}^m \bar{Q}_i \gamma_5 Q_i \frac{m n^2 f_T}{f_S} \frac{M_{Q_i}}{\sqrt{f_T^2 m^2 n^2 + f_S^2}} \right]. \quad (4.3)$$

Summing over the $(m + 1)$ quarks in computing a $G\tilde{G}$ coefficient, one obtains

$$\frac{1}{f_a} = \frac{f_S}{f_T} \frac{1}{\sqrt{f_T^2 m^2 n^2 + f_S^2}} + (m \times m n^2) \frac{f_T}{f_S} \frac{1}{\sqrt{f_T^2 m^2 n^2 + f_S^2}}. \quad (4.4)$$

This simplifies to

$$f_a = \frac{f_T f_S}{\sqrt{f_T^2 m^2 n^2 + f_S^2}}. \quad (4.5)$$

In this model we have $c_S = m n f_T / \sqrt{f_T^2 m^2 n^2 + f_S^2}$, $c_T = -f_S / \sqrt{f_T^2 m^2 n^2 + f_S^2}$ for the c_i factors defined in Eq. (3.18). Thus, using the value of f_a given in Eq. (4.5) we get

$$N_{\text{DW}} = \text{minimum integer}(m n n_1 - n_2). \quad (4.6)$$

Choosing $n_1 = 1$, $n_2 = m n - 1$ gives the minimum (positive) integer which is $N_{\text{DW}} = 1$. Thus, this family of models are free of cosmological difficulties associated with domain walls.

4.1 Axion quality in Model II

A gravity-induced operator involving the scalar fields T and S

$$V_{\text{gravity}} = \frac{\kappa e^{i\delta}}{(mn)!} \frac{S^{mn} T^*}{M_{\text{Pl}}^{mn-3}} + h.c. \quad (4.7)$$

can lead to a shift in $\bar{\theta}$. This term would lead to an axion potential given by

$$V_{\text{gravity}}^a = \frac{f_S^{mn} f_T \kappa}{2^{(mn-1)/2} (mn)! M_{\text{Pl}}^{mn-3}} \cos\left(\frac{a}{f_a} + \delta\right). \quad (4.8)$$

Minimizing this potential, along with that of Eq. (2.1), will induce a $\bar{\theta}$ given by

$$\bar{\theta} \simeq \frac{\kappa \sin \delta}{2^{(mn-1)/2} (mn)!} \frac{(m_u + m_d)^2}{m_u m_d} \frac{1}{f_\pi^2 m_\pi^2} \frac{f_S^{mn} f_T}{M_{\text{Pl}}^{mn-3}}. \quad (4.9)$$

This equation reduces to Eq. (3.12) for the case of $m = 3$. For $m > 3$, $\bar{\theta}$ is more suppressed than for the case of $m = 3$. For example, for $m = 4$ and with $f_S = f_T = f_a \sqrt{1 + m^2 n^2}$ we find

$$|\bar{\theta}| \simeq \begin{cases} 1.2 \times 10^{-57} & (n = 4, f_a = 5 \times 10^{10} \text{ GeV}) \\ 2.7 \times 10^{-25} & (n = 3, f_a = 5 \times 10^{10} \text{ GeV}) \end{cases}. \quad (4.10)$$

In this case, axion quality allows for a lower value of the integer, $n = 3$, compared to $n = 4$ that was used in Model I.

As for loop-induced corrections to $\bar{\theta}$, there are four set of terms involving VLQs, analogous to Eq. (3.14). They are given by

$$\begin{aligned} \mathcal{L}_{\text{gravity}}^{\text{Yuk}} = & \kappa_{ab} \frac{(\bar{Q}_{aL} Q_{bR})^m T}{M_{\text{Pl}}^6} + \kappa_{m+1, m+1} \frac{\bar{Q}_{m+1, L} Q_{m+1, R} (S^*)^{mn}}{(mn)! M_{\text{Pl}}^{mn-1}} \\ & + \kappa_{a, m+1} \frac{\bar{Q}_{aL} Q_{m+1, R} (S^*)^{\frac{n(m-1)}{2}}}{\left(\frac{n(m-1)}{2}\right)! M_{\text{Pl}}^{\frac{n(m-1)}{2}-1}} + \kappa_{m+1, a} \frac{\bar{Q}_{m+1, L} Q_{aR} (S^*)^{\frac{n(m-1)}{2}}}{\left(\frac{n(m-1)}{2}\right)! M_{\text{Pl}}^{\frac{n(m-1)}{2}-1}} + h.c. \end{aligned} \quad (4.11)$$

Here the last two terms are allowed only when $n(m-1)/2$ is an integer. The case of $m = 3$ reduces to Eq. (3.14). These operators will lead through loops analogous to Fig. 1 and Fig. 2 to purely scalar operators of the form $S^{mn} T^*$. However, these effects are much more suppressed for $m > 3$ compared to the case of $m = 3$. For example, the equivalent of Fig. 1 would have m loops. We conclude that for $m > 3$ the axion quality constraint is easily satisfied.

4.2 A special case of $m + 1 \geq 10$ and $n = 1$ in Model II

The case of $m + 1 \geq 10$ in Model II allows for the choice $n = 1$ (see charges listed in Table 2). With this choice, the Yukawa couplings of all vector-like quarks are allowed at the renormalizable level. They are given as

$$-\mathcal{L}_{\text{Yuk}} = Y_{m+1} \bar{Q}_{m+1, L} Q_{m+1, R} T^* + \sum_{i=1}^m Y_i \bar{Q}_{iL} Q_{iR} S + h.c. \quad (4.12)$$

This subclass of Model II is very interesting since it is already UV complete. The lowest order gravity-induced $U(1)_{\text{PQ}}$ symmetry breaking term among scalars is $S^m T^*/M_{\text{Pl}}^{m-3}$. For $m \geq 9$, these operators have at least six powers of M_{Pl} suppression, which are safe from destabilizing the axion solution.

This special case of models is in some sense analogous to the Barr-Seckel models [20]. Both require at least ten vector-like fermions for axion quality. Both are renormalizable models. These are, however, different models with differing predictions for certain observables. In our subclass of Model II, the domain wall number is always one, while it can be more than one in the Barr-Seckel models. In Appendix A, we have briefly reviewed the Barr-Seckel framework for comparison, where we also discuss the possibility of addressing the cosmological domain wall problem in that setup by relying on the gravity-induced operators.

5 Model III: A high quality $SO(10)$ axion model

The similarity of the seesaw scale for neutrino mass generation and the invisible axion scale has over the years, inspired many works on the non-supersymmetric $SO(10)$ as well as other models for the invisible axion [46, 49–58]. These works, however, do not address the problem of Planck scale effects and hence they leave the axion quality problem untouched. In this section, we present a realistic grand unified model based on the $SO(10)$ gauge group which solves the quality problem in a similar way to Models I and II presented here, by making use of an axial $U(1)_a$ gauge symmetry. A brief account of the results in this section has been presented in Ref. [23]. Here we provide further details and also extend our analysis to include loop-induced effects that may affect the axion quality.

The fermions and scalars of the $SO(10) \times U(1)_a$ gauge model are listed in Table 3 where their representations and $U(1)_a$ charges are shown. The fermion sector of the model includes three copies of the SM fermions grouped under $\mathbf{16}_a$ ($a = 1 - 3$), as well as a $\mathbf{10}$ and four SM singlet fermions (χ, N_a). This choice allows for realizing $U(1)_a$ as a gauge symmetry in a simple way. All gauge anomalies cancel, as can be seen from these conditions:

$$\begin{aligned}
A[SO(10)^2 \times U(1)_g] &= 3 \times 2 \times 1 + 1 \times 1 \times (-6) = 0 \\
A[(\text{gravity})^2 \times U(1)_g] &= 3 \times 16 \times 1 + 1 \times 10 \times (-6) + 1 \times 1 \times 12 + 2 \times 1 \times (-4) \\
&\quad + 1 \times 1 \times 8 = 0 \\
A[(U(1)_a)^3] &= 3 \times 16 \times (1)^3 + 1 \times 10 \times (-6)^3 + 1 \times 1 \times (12)^3 + 2 \times 1 \times (-4)^3 \\
&\quad + 1 \times 1 \times (8)^3 = 0 .
\end{aligned} \tag{5.1}$$

Also listed in Table 3 are the charges of various fields under a global $U(1)$, which is accidental within the model. This global $U(1)$ charges are not uniquely determined, since any linear combination of a global $U(1)$ and the gauged $U(1)_a$ is also an equally good global symmetry.

Fermion	$SO(10)$ irrep	gauge $U(1)_a$ charge	global $U(1)$ charge
ψ_a	$\mathbf{16}_a$	+1	+1
F	$\mathbf{10}$	-6	0
χ	$\mathbf{1}$	+12	0
$N_{1,2,3}$	$\mathbf{1}$	(-4, -4, +8)	(0, 0, +2)
Scalar	$SO(10)$ rep	$U(1)_a$ charge	global $U(1)$
H	$\mathbf{10}$	-2	-2
H'	$\mathbf{10}$	0	0
$\bar{\Delta}$	$\overline{\mathbf{126}}$	-2	-2
T	$\mathbf{1}$	+1	+1
S	$\mathbf{1}$	+12	0
A	$\mathbf{45/210}$	0	0

Table 3: Fermion and scalar multiplets of the $SO(10) \times U(1)_a$ model that solves the axion quality problem. There are three copies of $\mathbf{16}_a$ fermions, corresponding to three generations. All fermion fields are taken to be left-handed. The last column lists an accidental global $U(1)$ symmetry present in the model, with a QCD anomaly which will be identified as $U(1)_{\text{PQ}}$. The multiplet A could either be a $\mathbf{45}$ or a $\mathbf{210}$ of $SO(10)$. The Higgs 10-plet H is complex, while H' is real.

The Yukawa Lagrangian of the model, consistent with the gauge symmetries, is given by

$$\begin{aligned}
\mathcal{L}_{\text{Yuk}} = & \psi^T (Y_{10} H + Y_{126} \bar{\Delta}) \psi + FFS + \chi\chi(S^*)^2/M_{\text{Pl}} \\
& + FN_3H + \chi N_{1,2}(T^4 S^*/M_{\text{Pl}}^4 + T^{*8}/M_{\text{Pl}}^7) \\
& + \sum_{a,b=1,2} N_a N_b (T^{*4} S/M_{\text{Pl}}^4 + T^8/M_{\text{Pl}}^7) + N_{1,2} N_3 T^{*4}/M_{\text{Pl}}^3 + h.c. \quad (5.2)
\end{aligned}$$

In Eq. (5.2) Y_{10} and Y_{126} are symmetric Yukawa coupling matrices that lead to a realistic and predictive fermion spectrum. In particular, the model accommodates large neutrino mixing angles simultaneously with small quark mixing angles. The predictions of the Yukawa sector for neutrino oscillations and charged fermion masses have been analyzed extensively in a variety of papers [59–76].

The FFS term in Eq. (5.2) induces a mass for the 10-plet fermion, which is needed for consistency. Eq. (5.2) also contains certain non-renormalizable operators that are induced by gravity with appropriate powers of M_{Pl} suppression, with the fourth term inducing a TeV-scale mass for the singlet fermion χ . The coupling FN_3H plays an important role in the decay of the color-triplet fermion, $F \rightarrow \bar{N}_3 + \bar{t} + \bar{b}$, through the exchange of the color-triplet scalar in H . The lifetime for this decay can be estimated to be of order 10^{-11} sec., with the masses of the color-triplet fermion and scalar being at the GUT scale, which is compatible with big bang nucleosynthesis (BBN) constraints. The remaining terms in

Eq. (5.2) lead to sub-eV masses for the singlet fermions N_a .

The most general Higgs potential for the model has been studied in Ref. [50] for the $SO(10)$ sector. Here we write down the relevant terms symbolically, focusing on nontrivial invariants (for $A = \mathbf{45}$), including the singlet fields:

$$V \supset HH'T^2 + H\Delta AA + \Delta\Delta HH + \Delta\bar{\Delta}\Delta H \\ + \Delta\bar{\Delta}HH^* + \Delta\bar{\Delta}\Delta\bar{\Delta} + T^{12}S^*/M_{\text{Pl}}^9 + h.c. \quad (5.3)$$

This potential leads to the mixing of Higgs doublets from $\mathbf{10}$ and $\mathbf{126}$, which is needed for realistic fermion mass generation. The first term in Eq. (5.3), $HH'T^2$ is needed to avoid a weak-scale axion. The Higgs potential has an accidental global $U(1)_{\text{PQ}}$ symmetry with the charges listed in the fourth column of Table 3. Note that this global $U(1)$ has a QCD anomaly, with a coefficient of +6. This global symmetry, however, is not respected by quantum gravity, and is broken explicitly by the Planck-suppressed operator in the last term of Eq. (5.3). Owing to its high dimensionality its contribution to the shift in $\bar{\theta}$ is small, which is why the model has no axion quality problem.

5.1 Identifying the axion field

The axion field should be orthogonal to the Goldstone bosons eaten up by the gauge bosons, as well as to physical scalar fields that acquire masses through the Higgs potential. It is convenient to utilize the branching rule for $SO(10) \supset SU(5) \times U(1)_X$, which for the fields of interest are given by

$$10 \rightarrow 5(2) + \bar{5}(-2) \\ \bar{126} \rightarrow 1(10 + 5(2) + \bar{45}(-2) + \dots \\ 45 \rightarrow 1(0) + 24(0) + \dots \quad (5.4)$$

Here we have only kept fields that contain SM singlets or doublets, since only these components have neutral members that can acquire vacuum expectation values and the axion field would be composed of one combination of these fields. We denote the SM doublet fields from the H and $\bar{\Delta}$ and the SM singlets from $\bar{\Delta}$ and A fields as:

$$H \supset H_u^{10}(2, -2) + H_d^{10}(-2, -2) \\ \bar{\Delta} \supset H_u^{126}((2, -2) + H_d^{126}(-2, -2) + 1_{126}(10, -2) \\ H' \supset H^{10'}(2, 0) + H^{*10'}(-2, 0) \\ A \supset 1_{45}(0, 0) + 1'_{45}(0, 0). \quad (5.5)$$

Here the $U(1)_X \times U(1)_a$ charges are indicated for each component. The $H^{10'}(2, 0)$ is defined to have $Y/2 = +1/2$ and $H^{*10'}(-2, 0)$ is its conjugate.

It is straightforward to identify the combination of SM doublet and singlet fields that appear in the potential of Eq. (5.3). In particular, the following terms involving the SM doublet fields arise when Eq. (5.3) is expanded and the SM singlet VEVs are inserted:

$$V \supset a_u (H_u^{126\dagger} H_u^{10}) + a_d (H_d^{126\dagger} H_d^{10}) + a_{ud} (H_u^{126\dagger} H_u^{10})(H_d^{126\dagger} H_d^{10}) \\ + a_{du} (H_u^{126\dagger} H_u^{10})(H_d^{10\dagger} H_d^{126}) + a_{uu} (H_u^{126\dagger} H_u^{10})^2 \\ + a_{dd} (H_d^{126\dagger} H_d^{10})^2 + a'_u (H^{10'\dagger} H_u^{10}) T^2 + a'_d (H_d^{10} H^{10'}) T^2 + h.c. \quad (5.6)$$

Each of the neutral field which acquires a VEV that is in general complex, can be parameterized as

$$\Phi_i = \frac{1}{\sqrt{2}}(\rho_i + v_i e^{i\alpha_i})e^{i\eta_i/v_i} \quad (5.7)$$

where v_i and η_i are real parameters. Freezing the radial components ρ_i , which are irrelevant for axion identification, we parameterize

$$\begin{aligned} H_u^{10} &= \frac{v_u e^{i\alpha_u}}{\sqrt{2}} e^{i\frac{\eta_u}{v_u}}, & H_u^{\overline{126}} &= \frac{v'_u e^{i\alpha'_u}}{\sqrt{2}} e^{i\frac{\eta'_u}{v'_u}}, & H_d^{10} &= \frac{v_d e^{i\alpha_d}}{\sqrt{2}} e^{i\frac{\eta_d}{v_d}}, & H_d^{\overline{126}} &= \frac{v'_d e^{i\alpha'_d}}{\sqrt{2}} e^{i\frac{\eta'_d}{v'_d}}, \\ \tilde{H}^{10} &= \frac{\tilde{v} e^{i\tilde{\alpha}}}{\sqrt{2}} e^{i\frac{\tilde{\eta}}{\tilde{v}}}, & \Delta_R^{\overline{126}} &= \frac{v_R e^{i\alpha_R}}{\sqrt{2}} e^{i\frac{\eta_R}{v_R}}, & S &= \frac{v_S e^{i\alpha_S}}{\sqrt{2}} e^{i\frac{\eta_S}{v_S}}, & T &= \frac{v_T e^{i\alpha_T}}{\sqrt{2}} e^{i\frac{\eta_T}{v_T}}. \end{aligned} \quad (5.8)$$

The two SM singlets from **45** do not contribute to the axion field, and are left out here. By separate gauge and PQ rotations we have made the VEVs (v_S, v_T, v_R) real, while the Higgs doublet VEVs are in general complex.

Inserting Eq. (5.8) into Eq. (5.6), we identify four massive pseudoscalar fields:

$$\begin{aligned} \mathcal{A}_1 &= N_1 \left[\frac{\eta_u}{v_u} - \frac{\eta'_u}{v'_u} \right] \\ \mathcal{A}_2 &= N_2 \left[\frac{\eta_d}{v_d} - \frac{\eta'_d}{v'_d} \right] \\ \mathcal{A}_3 &= N_3 \left[2\frac{\eta_T}{v_T} + \frac{\eta_u}{v_u} - \frac{\tilde{\eta}}{\tilde{v}} \right] \\ \mathcal{A}_4 &= N_4 \left[2\frac{\eta_T}{v_T} + \frac{\eta_d}{v_d} + \frac{\tilde{\eta}}{\tilde{v}} \right]. \end{aligned} \quad (5.9)$$

The three Goldstone fields, which are eaten up by the longitudinal components of (Z, X, V_a) with V_a being the gauge boson associated with $U(1)_a$, are identified as:

$$\begin{aligned} G_Z &= N_Z(v_u \eta_u + v'_u \eta'_u - v_d \eta_d - v'_d \eta'_d + \tilde{v} \tilde{\eta}) \\ G_X &= N_X(10 v_R \eta_R + 2 v_u \eta_u + 2 v'_u \eta'_u - 2 v_d \eta_d - 2 v'_d \eta'_d + 2 \tilde{v} \tilde{\eta}) \\ V_a &= N_a(-2 v_R \eta_R + v_T \eta_T + 12 v_S \eta_S - 2 v_u \eta_u - 2 v'_u \eta'_u - 2 v_d \eta_d - 2 v'_d \eta'_d). \end{aligned} \quad (5.10)$$

The axion field is the combination orthogonal to the seven fields listed in Eq. (5.9) and Eq. (5.10), which can be written down as:

$$a = N(c_S \eta_S + c_T \eta_T + c_u \eta_u + c'_u \eta'_u + c_d \eta_d + c'_d \eta'_d + \tilde{c} \tilde{\eta}). \quad (5.11)$$

It is convenient to make a few definitions in order to write down the coefficients appearing in Eq. (5.11):

$$\begin{aligned} V_u^2 &= v_u^2 + v'^2_u, & V_d^2 &= v_d^2 + v'^2_d, & v^2 &= V_u^2 + V_d^2 + \tilde{v}^2 \\ X &= v_T^2 v^2 + 4 \tilde{v}^2 (V_u^2 + V_d^2) + 16 V_u^2 V_d^2 \\ \tan \beta_u &= \frac{v'_u}{v_u}, & \tan \beta_d &= \frac{v'_d}{v_d} \end{aligned} \quad (5.12)$$

with $v^2 = (174 \text{ GeV})^2$. In terms of these quantities, the coefficients c_α in Eq. (5.11) can be written as:

$$\begin{aligned}
c_S &= X, & c_T &= -12 v_S v_T v^2 \\
c_u &= 24 v_S V_u (2 V_d^2 + \tilde{v}^2) \cos \beta_u \\
c'_u &= 24 v_S V_u (2 V_d^2 + \tilde{v}^2) \sin \beta_u \\
c_d &= 24 v_S V_d (2 V_u^2 + \tilde{v}^2) \cos \beta_d \\
c'_d &= 24 v_S V_d (2 V_u^2 + \tilde{v}^2) \sin \beta_d \\
\tilde{c} &= 24 v_S \tilde{v} (V_d^2 - V_u^2) \\
N &= 1/\sqrt{X(X + 144 v_S^2 v^2)}.
\end{aligned} \tag{5.13}$$

It is interesting to note that the η_R field has disappeared from a . Furthermore, since $v^2 \ll v_S^2, v_T^2$ we have $X \simeq v_T^2 v^2$ and $N \simeq 1/(v_T^2 v^2 \sqrt{1 + 144 v_S^2/v_T^2})$.

It is straightforward to compute the coupling of the axion to the gluon fields. This coupling is induced through the $\eta_{u,d}$ and $\eta_{u',d'}$ content of Eq. (5.11) through their couplings to the quarks in **16**-fermions as well as from the η_S component through its couplings to the quarks in the **10**-fermion. Our calculation shows

$$\mathcal{L}_{aG\tilde{G}} = \frac{\alpha_s}{8\pi f_a} a G_{\mu\nu}^a \tilde{G}^{a,\mu\nu}, \quad f_a = v_S / \sqrt{1 + \frac{144 v_S^2 v^2}{X}}. \tag{5.14}$$

Note that the rotation matrices that are used to diagonalize the quark mass matrices do not appear in the axion coupling to the physical quarks in the model, since the coupling matrices are proportional to the quark mass matrices.

6 Phenomenology of the SO(10) axion

In this section, we present some of the phenomenological implications of the $SO(10) \times U(1)_a$ model, starting with a discussion of the quality constraint on the scales of the model. We shall also see that the model interpolates between the KSVZ- and the DSFZ-axion models.

6.1 Quality constraint

From the gauge quantum numbers of the various fields in the model (Cf: Table 3), we find that the leading gravity-induced PQ symmetry breaking term is

$$V_{\text{gravity}} = \frac{\kappa e^{i\delta} T^{12} S^*}{(12)! M_{\text{Pl}}^9} + h.c. \tag{6.1}$$

This shifts the minimum of the axion potential from $\bar{\theta} = 0$ to a finite value given by

$$\bar{\theta} \simeq \frac{\kappa \sin \delta}{(12)! 2^{11/2}} \frac{f_a v_T^{12}}{M_{\text{Pl}}^9 m_\pi^2 f_\pi^2} \frac{(m_u + m_d)^2}{m_u m_d} \frac{\left(1 + \frac{144 v_S^2}{v_T^2}\right)}{\sqrt{1 + \frac{144 v_S^2 v^2}{X}}}. \tag{6.2}$$

Defining

$$r \equiv \frac{v_S^2}{v_T^2}, \quad (6.3)$$

and using the approximate relation $X \simeq v_T^2 v^2$, this simplifies to

$$\bar{\theta} \simeq \left(\frac{\kappa \sin \delta}{(12)! 2^{11/2}} \right) \left(\frac{f_a^{13}}{f_\pi^2 m_\pi^2 M_{\text{Pl}}^9} \right) \frac{(m_u + m_d)^2}{m_u m_d} \left(\frac{(1 + 144r)^{13/2}}{r^6} \right) \quad (6.4)$$

The third factor which depends on the ratio r in this equation has a minimum at $r = 1/12$, in which case its value is $14412774445056\sqrt{13} = 5.1966 \times 10^{13}$. Using $\kappa \sin \delta = 1$, $M_{\text{Pl}} = 1.22 \times 10^{19}$ GeV, the maximum value for f_a that keeps $\bar{\theta} \leq 10^{-10}$ is found to be $f_a < 4.2 \times 10^{11}$ GeV, where the minimum value of the function in the third bracket is assumed. If the symmetry factor of $1/12!$ is not included in Eq. (6.1), the largest allowed value of f_a would be reduced by about a factor of 4, to $f_a \leq 1 \times 10^{11}$ GeV.

6.2 Loop effects on quality constraint

It has been pointed out to us⁴ that in generic high quality axion models, one could have more dominant (hence less Planck suppressed) operators which by themselves do not affect the quality discussion but they may affect it via loop corrections. The latter may lead to less Planck mass suppressed operators in the scalar potential. These would in general put constraints on the Higgs coupling parameters of the model in order to realize acceptable values for f_a . We have investigated this issue within our model, as we now discuss.

In our model, an operator of the form $H^6 S/M_{\text{Pl}}^3$ is allowed by the gauge symmetry. While it does not affect the axion quality at tree-level, when combined with the renormalizable coupling $(\lambda/2) HH'T^2$ of Eq. (5.3), this coupling would induce an operator $T^{12} S^*$ through a three-loop diagram shown in Fig. 4. This induced operator has only three powers of M_{Pl} suppression, as opposed to six powers seen in Eq. (6.1). Writing the $HH'T^2$ coupling as $\lambda/2(H_u H_d + H_c H_c^*)T^2$, with H_c denoting the color triplet scalar, we find that the three-loop induced correction to the scalar potential that breaks the PQ symmetry, taking advantage of the $d = 7$ Planck-induced operator $\gamma H^6 S/(6! M_{\text{Pl}}^3)$ to be

$$V \supset g_n \gamma \left(\frac{\lambda^2}{16\pi^2} \right)^3 \frac{T^{12} S^*}{12! M_{H'}^6 M_{\text{Pl}}^3} \left\{ \frac{3}{2} + 2 \ln \left(\frac{M_{H_d}^2 - 4M_T^2}{M_{H'}^2} \right) \right\}^3. \quad (6.5)$$

Here the first term in the curly bracket arises from the exchange of color triplets, which are assumed to have GUT scale mass, taken to be the same as the H' mass. The second term arises from the exchange of $SU(2)_L$ doublets H_u and H_d , with H_u mass being near the weak scale and thus ignored. (Note that the light Higgs doublet is almost entirely arising from H_u in this model.) The mass of H_d from 10_H is of the same order as the mass of T , and we have assumed in deriving Eq. (6.5) that $M_{H'} \gg M_{H_d} > 2M_T$. The symmetry factor g_n in Eq. (6.5) is found to be

$$g_n = \frac{1}{3!} \frac{1.3.5}{(2!)^3} 6! = 225. \quad (6.6)$$

⁴Vasja Susi c, private communications.

Figure 4: Three loop diagram that contributes to $U(1)_{\text{PQ}}$ symmetry breaking in the $SO(10)$ model.

Choosing as an example $M_{H'} = 2 \times 10^{16}$ GeV, $M_T = 1 \times 10^{11}$ GeV and $M_{H_d} = 6 \times 10^{11}$ GeV, we find that these loop-induced contributions become comparable to the $d = 12$ gravity-induced contribution of Eq. (6.1) to $\bar{\theta}$ when the quartic coupling $\lambda \geq 0.003$ (for $|\gamma| \simeq |\kappa|$). Thus, these loop corrections, while important, do not upset the axion quality.

There is also a less Planck suppressed Higgs coupling of the form $(\Delta)^6 S^*/M_{\text{Pl}}^3$ term but this term does not lead to anything that would affect the quality constraint like the operator $H^6 S/M_{\text{Pl}}^3$.

6.3 Axion couplings

To study other phenomenological implications of the model, we calculate the two photon coupling of the axion, denoted as E . Using the same techniques used for calculating gluon coupling of axion, we find that

$$g_{a \rightarrow \gamma\gamma} = \frac{\alpha_{em} C_{em}}{2\pi f_a} \quad (6.7)$$

where $C_{em} = \frac{8}{3} - 1.92$. The first term in C_{em} comes from the triangle diagrams with fermion lines in the loop while the second model independent term comes from the non-perturbative QCD effects e.g. $a - \pi^0$ mixing [16, 77–79].

The axion coupling to electron and nucleon have the form given in Eq. (1.2) with the C_{af} -factors given by

$$\begin{aligned} C_{ae} &= \frac{24r}{1 + 144r} K_e \\ C_{ap} &= -0.47 + \frac{r}{1 + 144r} (20.75K_u - 10.49K_e) \\ C_{an} &= -0.02 + \frac{r}{1 + 144r} (19.99K_e - 9.73K_u). \end{aligned} \quad (6.8)$$

Figure 5: $|\bar{\theta}|$ vs f_a . $\bar{\theta}$ includes the three-loop contribution in Fig. 4. The orange and blue points are shown for $\lambda = 0.1$ and 0.01 respectively. The $|\theta| \leq 10^{-10}$ region is indicated by the arrow. The gray shaded band denotes the DM abundance constraint.

Figure 6: In this figure, we have imposed the quality constraint on the parameters of the model and present the allowed values of the f_a as a function of the ratio of the two high scale VEVs v_S and v_T . The gray shaded band denotes the values of f_a for which the DM abundance is satisfied

Here we have defined

$$K_u = \frac{2V_d^2 + \tilde{v}^2}{v^2}, \quad K_e = \frac{2V_u^2 + \tilde{v}^2}{v^2}. \quad (6.9)$$

Figure 7: The plot of the ratio g_{ae}/g_{ag} as a function of f_a for our model (blue points) and the DFSZ model, the range covered by the black points. Here we have used $\alpha_s(2 \text{ GeV}) = 0.32$ and varied $\tan\beta$ in the range $\tan\beta = \{0.25, 170\}$. We also show the region allowed by the DM abundance.

K_e has a range $(1.5 - 2)$ corresponding to $\tilde{v} = v_u$ and $\tilde{v} \ll v_u$. The value of K_u can be much smaller, with an upper limit of 0.5 (corresponding to $\tilde{v} = v_u$). This gives a range $c_e = (.25 - .33)$.

The prediction of $g_{a \rightarrow \gamma\gamma}$ in our model is the same as in the DFSZ model, while that for $g_{a \rightarrow ee}$ is very different. The magnitude of the latter is much smaller, e.g., $g_{a \rightarrow ee}$ has an upper limit of $c_e^{max} = 0.33$. If the electron coupling of the axion is measured to be larger than this value, our model will be ruled out. For comparison, note that in the KSVZ model $g_{ae} \approx 0$ and in the DFSZ-I model it is $(1/3)\sin^2\beta(m_e/f_a)$ while in DFSZ-II, it is $(-1/3)\cos^2\beta(m_e/f_a)$ [15], where $\tan\beta = v_u/v_d$. (The DFSZ-I model is defined as the one in which H_d couples to leptons, whereas the DFSZ-II model has \hat{H}_u coupling to leptons.)

To estimate the nucleon couplings of the axion, we note that there is a universal model-independent contribution from the gluon part and model dependent contributions. Keeping only the dominant u and d quark contributions, we get

$$\begin{aligned} C_{ap} &= -0.47 + 0.88c_u - 0.39c_d + (\text{small } s, c, b, t \text{ contributions}) \\ C_{an} &= -0.02 + 0.88c_d - 0.39c_u (\text{small } s, c, b, t \text{ contributions}) \end{aligned} \quad (6.10)$$

6.4 Predictions of the $SO(10)$ Model

In order to derive the predictions for the $SO(10)$ model, we vary all the VEVs, i.e., $v_S, v_T, v_{u,d}^0$ and \tilde{v} while satisfying $v^2 = v_u^2 + v_d^2 + \tilde{v}^2$ and the angles (β_u, β_d) . In our analysis we

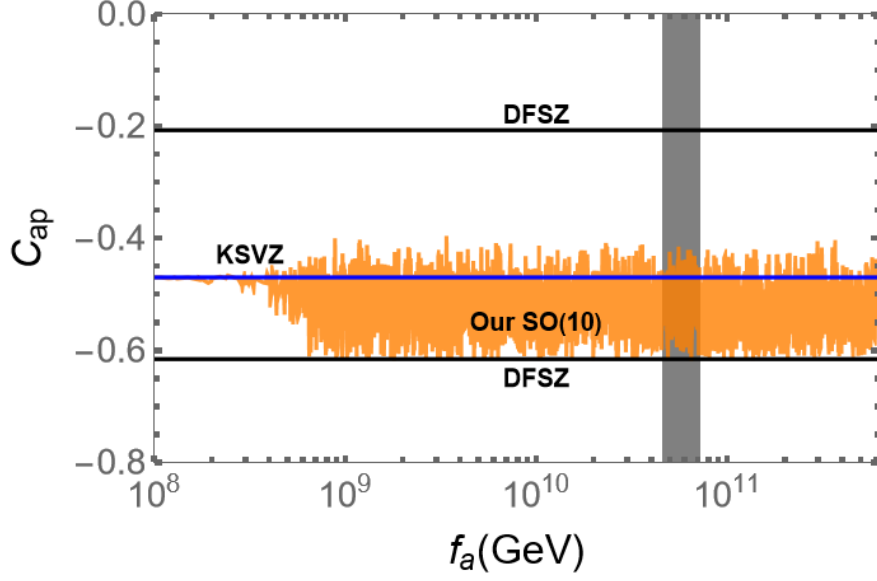

Figure 8: This plot shows the axion proton coupling as a function of the axion decay constant f_a .

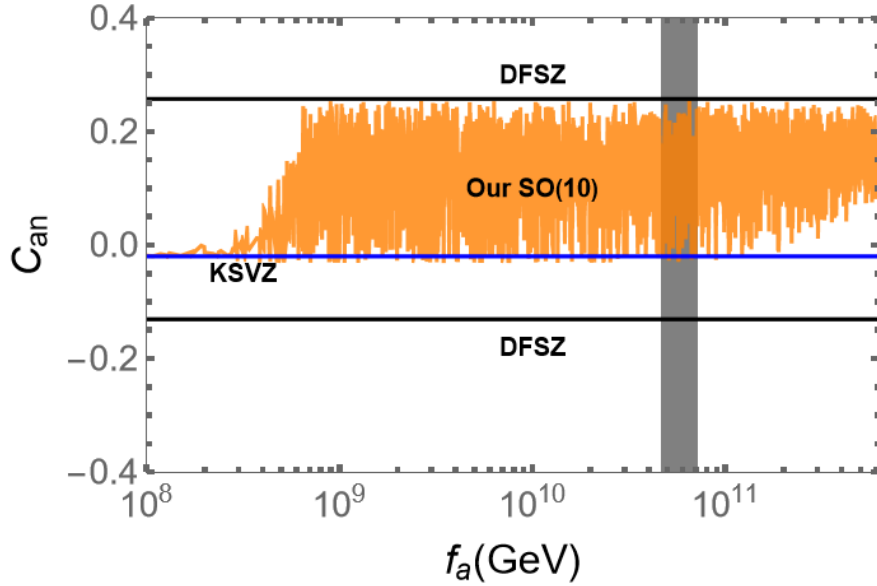

Figure 9: This plot gives the axion neutron coupling as a function of the axion decay constant f_a .

have used the constraints on fermion mass fit which fixes the VEV ratios $|v_u/v_d| \simeq 70.3$ and $v'_u/v'_d \simeq |18.1 + 3.7i|$ [76].

In Fig. 5, we calculate $|\bar{\theta}|$ for the model points as a function of f_a for two different values of $\lambda = 0.1$ and 0.01 after including the loop contributions as given in Eq. (6.5).

Figure 10: Axion proton (top)/neutron (bottom) vs axion-electron couplings for $4.6 \times 10^{10} \leq f_a(\text{GeV}) \leq 7.2 \times 10^{10}$ where axions can be 100% DM.

We also show (gray band) the constraint of the relic abundance for $N_{\text{DW}} = 1$ as obtained in Ref. [47, 80], i.e., $f_a = (4.6 - 7.2) \times 10^{10}$ GeV for $\Omega_a \simeq 0.12h^2$. This range of f_a for axions providing 100% DM is also consistent with the results of Ref. [48]. We find that both values λ are allowed by $|\bar{\theta}| \leq 10^{-10}$ and the relic abundance.

In Fig. 6, we plot the ratio $|v_S/v_T|$ as a function of f_a for the choice of λ to satisfy the quality constraint. The values of $|v_S/v_T|$ lie mostly in the range 0.1 to 10.

We calculate the coupling ratio $\frac{g_{ae}}{g_{ag}}$ (where $g_{ae} = m_e C_{ae}/f_a$ and g_{ag} is the axion-gluon coupling) as a function f_a in Fig. 7 and we find that our model predicts a positive value for this quantity. The predictions of the $SO(10)$ model are not allowed in the DFSZ II-permitted regions. Similarly, for C_{ap} and C_{an} , the axion-nucleon couplings, we show that if the experimental values fall outside the orange shaded region in Figs. 8 and 9, the $SO(10)$

model will be ruled out.

In Fig. 10, we show g_{ae} vs axion-proton(neutron) $g_{ap,n} \equiv m_{p,n}C_{ap,n}/f_a$ for f_a satisfying the DM constraint. The correlated model points for this range of f_a can be distinguished from KSVZ and DFSZ-II but have overlaps with the DFSZ-I model.

6.5 $SO(10)$ model as a Hybrid axion model

In this subsection, we argue that our $SO(10)$ model is a hybrid between the KSVZ and DFSZ models. We note that the ratio $r = \frac{v_S^2}{v_T^2}$ interpolates between the KSVZ and DFSZ models, as can be seen from the axion composition of the model in Eq. (5.11). As $r \rightarrow 0$, axion mostly consists of the field η_S (case (i)) whereas in the other limit when $r \rightarrow \infty$ axion mostly consists of η_T (case(ii)). Looking at the Yukawa couplings in Eq. (5.2) and Higgs potential in Eq. (5.3), we see that in case (i), the singlet S which contains the axion couples mostly to vector-like **10**-plet fermions like in the KSVZ model whereas in case (ii), the axion, being mostly in T , does not couple to SM quarks like in the DFSZ model.

This interpolation is also reflected in Figs. 7-10, and Eq. (6.8). As $r \rightarrow 0$, the couplings to e, p and n reduce to the KSVZ values whereas for $r \rightarrow \infty$ it goes to DFSZ-I values. This shows that r is indeed the interpolating parameter of the model and for arbitrary r , the predictions for the above observables are in the orange region of Figs. 7-10 and represent the hybrid nature of our model interpolating between KSVZ and DFSZ-I cases.

6.6 Domain Wall in the $SO(10)$ model

To get the domain wall number in the $SO(10)$ model, we employ the same prescription as in the case of model I using Eq. (3.19), viz.,

$$N_{\text{DW}} = \text{minimum integer} \left\{ \frac{1}{f_a} \sum_i n_i c_i f_i, \quad n_i \in \mathcal{Z} \right\}. \quad (6.11)$$

In our $SO(10)$ model, there are seven c_i 's which are listed in Eq. (5.13), and therefore there are seven n_i 's in the above equation. It is easy to see that for $n_{2,\dots,7} = 0$ and $n_1 = 1$ we get a solution to Eq. (6.11). The number of domain walls in this model is one. Therefore, the model has no cosmological domain wall problem.

6.7 Other cosmological issues

The fermion fields $N_{1,2,3}$ of the model have masses that lie in the sub-eV range, since they arise from Planck suppressed operators. As a result, these fields can affect BBN. However, the $N_{1,2,3}$ fields interact with the SM particles only by the exchange of the $U(1)_a$ gauge boson. Since this gauge boson mass is of order $v_a \sim 10^{12}$ GeV, the N_i 's go out of equilibrium at $T_* \simeq v_a(v_a/M_{\text{Pl}})^{1/3} \simeq 10^9$ GeV. As a result, their contribution to the energy density at the epoch of BBN is small with $\Delta N_{\text{eff}} \simeq 0.13$. This prediction is in agreement with current CMB observations, but will be tested in the future in the next generation CMB experiments.

The singlet χ in our model, with its mass of order TeV, can potentially overclose the universe. This is because its interactions with the SM particles are very weak at $T \sim M_\chi$.

One resolution to this problem is to give χ a large mass, of order the PQ breaking scale, by introducing an $SO(10)$ singlet fermion N_0 with zero $U(1)_a$ charge. This new field would not affect the anomaly cancellation conditions, or other properties of the model. A new Yukawa coupling of the type $\chi N_0 S^*$ would now be allowed, which would give the $\chi - N_0$ pair a Dirac mass of order 10^{12} GeV. Additionally, a dimension-six four-fermion operator of the form $\chi N_1 N_1 N_1 / M_{\text{Pl}}^2$ is allowed in the Lagrangian. The decay $\chi \rightarrow 3N_1$ can now proceed since N_1 is light. The width for this decay is given by $\Gamma_\chi \sim (m_\chi^5 / M_{\text{Pl}}^4) / 192\pi^3 \sim 10^{-20}$ GeV. This decay occurs well before BBN, and thus leaves the success of BBN unaffected.

We make a few other remarks on the model.

- We briefly comment on the gauge symmetry breaking, which is very similar to $SO(10)$ models discussed in detail in the literature with **10**, **126** Higgs fields (see for instance Ref. [50]). The **45** + **54** Higgs fields breaks the $SO(10)$ down to $SU(3)_c \times SU(2)_L \times SU(2)_R \times U(1)_{B-L}$ symmetry, which is subsequently broken down to the standard model by the **126**-Higgs field. Here the **54** field is optional, which would enable consistent symmetry breaking with the tree-level Higgs potential. In its absence the **45** can break $SO(10)$ down to the left-right symmetric group, but requires loop corrections [81, 82]. Unification of gauge couplings in this setup has been studied in Re. [50, 82, 83]. The $U(1)_a$ gauge symmetry is broken by the singlet fields T, S which also break the accidental PQ symmetry.
- The neutrino masses as well as other SM fermion masses in this model follow from type-I seesaw. Extensive analysis in the non-supersymmetric version of similar $SO(10)$ models has been carried out in the literature [59–76], and they apply to our model. We also expect the standard leptogenesis scenarios to work for our case to generate matter-anti-matter asymmetry of the universe.
- For the choice of parameters in the $SO(10)$ model, where $f_a \sim (4 - 7) \times 10^{10}$ GeV, with $N_{\text{DW}} = 1$, the right amount of axion DM density of the universe is realized.

7 Summary

We have constructed a class of new axion models where the $U(1)_{PQ}$ symmetry arises as an accidental global symmetry, solving the strong CP problem. A major advantage of these models is that they solve the axion quality problem owing to the presence of a gauged axial $U(1)_a$ symmetry, which eliminates the dangerous low-order Planck scale induced $U(1)_{PQ}$ -violating operators. We have presented three examples of such models. The first class (called model I) extends the KSVZ invisible axion model with a gauged $U(1)_a$ symmetry acting on a set of vector-like quarks. Their axial $U(1)$ charges help in realizing a global $U(1)_{PQ}$ symmetry accidentally with a QCD anomaly. Our second class of models (model II), is a generalization of model I to a family of models. The third model is based on $SO(10) \times U(1)_a$, that uses fermions belonging to **16**, **10** as well as singlet representations under $SO(10)$. All the models are phenomenologically viable and have a high quality axion. We show that all the models have domain wall number $N_{\text{DW}} = 1$ and therefore

these models have no cosmological no issues, allowing for a post-inflationary PQ breaking scenario. We also give predictions for the axion coupling to photons and with matter for the $SO(10)$ model in the parameter space where axions can explain the total DM content so that they can be used to distinguish it from the standard KSVZ and DFSZ models. We have compared our model with the Barr-Seckel model of high quality axion, and pointed out that one realization of this framework has a domain wall problem which is shown to be reconciled from the Planck scale present in the model..

A Appendix: Barr-Seckel model

Here we give a brief summary of the Barr-Seckel model of high quality axion [20], which may be useful for a comparison of the models presented here. We also comment on the domain wall number in this framework and a possible way of evading the cosmological problems when N_{DW} turns out to be larger than one.

The model introduces $(p + q)$ quarks which transform as $(3, 1, 0)$ under SM gauge symmetry. p and q are relatively prime integers, with $(p + q) \geq 10$ needed to solve the quality problem. All left-handed quark fields carry zero charge under the gauged $U(1)$ while the right-handed quarks carry charges:

$$\{(p + q) \times Q_L(0) + p \times Q_R(q) + q \times Q_R(-p)\} . \quad (\text{A.1})$$

Here $(p + q)$, p and q are the multiplicities of the quark fields. All mixed anomalies cancel with this setup. One needs to ensure that the cubic $[U(1)]^3$ anomaly vanishes as well, which is achieved by introducing SM singlet fermions.

Two scalar fields, $S(-q)$ and $T(+p)$ are employed, which generate all quark masses via the Yukawa couplings

$$\mathcal{L}_{\text{Yuk}} = \sum_{i=1}^p \bar{Q}_{Li} Q_{Ri} S + \sum_{i=p+1}^{p+q} \bar{Q}_{Li} Q_{Ri} T + h.c. \quad (\text{A.2})$$

Denoting $S = (\rho_S + f_S)/\sqrt{2}e^{i\eta_S/f_S}$ and $T = (\rho_T + f_T)/\sqrt{2}e^{i\eta_T/f_T}$, the Goldstone boson eaten by the $U(1)$ gauge boson and the orthogonal axion field are given by

$$G = \frac{pf_T\eta_T - qf_S\eta_S}{\sqrt{p^2 f_T^2 + q^2 f_S^2}}, \quad a = \frac{pf_T\eta_S - qf_S\eta_T}{\sqrt{p^2 f_T^2 + q^2 f_S^2}} . \quad (\text{A.3})$$

The axion decay constant f_a is readily computed as

$$f_a = \frac{f_T f_S}{\sqrt{p^2 f_T^2 + q^2 f_S^2}} . \quad (\text{A.4})$$

Gravity-induced axion potential arises from

$$V_{\text{gravity}} = \frac{\kappa e^{i\delta} S^p T^q}{p! q! M_{\text{Pl}}^{p+q-4}} + h.c. \quad (\text{A.5})$$

This leads to an axion potential given as

$$V_{\text{gravity}}^{(a)} = \frac{2\kappa f_S^p f_T^q \cos(\frac{a}{f_a} + \delta)}{2^{(p+q)/2} p! q! M_{\text{Pl}}^{p+q-4}}. \quad (\text{A.6})$$

Minimizing this potential, along with the QCD-induced axion potential, yields

$$\bar{\theta} \simeq \frac{2\kappa \sin \delta}{2^{(p+q)/2} p! q!} \frac{f_S^p f_T^q}{f_\pi^2 m_\pi^2} \frac{(m_u + m_d)^2}{m_u m_d} \frac{1}{M_{\text{Pl}}^{p+q-4}}. \quad (\text{A.7})$$

If we choose $f_S = f_p = f_a \sqrt{p^2 + q^2}$, the following values of $\bar{\theta}$ are obtained corresponding to different choices of (p, q) and f_a , all for $\kappa \sin \delta = 1$:

$$|\bar{\theta}| \simeq \begin{cases} 5 \times 10^{-18} & (p = 1, q = 9, f_a = 10^9 \text{ GeV}) \\ 1 \times 10^{-17} & (p = 3, q = 7, f_a = 10^9 \text{ GeV}) \\ 4 \times 10^{-15} & (p = 1, q = 13, f_a = 10^{12} \text{ GeV}) \end{cases}. \quad (\text{A.8})$$

This results in a high quality axion.

Since $p + q = 10$ is the minimal choice of VLQs in the framework, we have investigated ways of UV-completing the model with choice $p = 1$ and $q = 9$, which are co-prime. Three singlet fermions with $U(1)$ charges of $(1, 15, -16)$ will cancel the linear anomaly, as well as the cubic anomaly. In the case, the Higgs fields S and T have charges 1 and 9. The couplings $N(15)N(-16)S$ and $N(1)N(1)S^2/M_{\text{Pl}}$ would generate masses for these singlets.

The domain wall number in this model can be found to be

$$N_{\text{DW}} = \text{minimum integer}(n_1 q + n_2 p). \quad (\text{A.9})$$

For the case of $(q, p) = (1, 9)$ one has $N_{\text{DW}} = 1$, which can be checked by choosing $(n_1, n_2) = (1, 0)$. On the other hand, if $(q, p) = (3, 7)$, which are also co-prime integers, $N_{\text{DW}} = 3$. We briefly outline how cosmological problem with $N_{\text{DW}} = 3$ may be evaded by using higher dimensional operators that break $U(1)_{\text{PQ}}$ explicitly.

A.1 Fate of the Domain Walls where $N_{\text{DW}} = 3$

Since this model has a Planck induced PQ breaking term, the different vacua will not be degenerate leading to decay of the domain walls as the universe evolves. The strength of this breaking term is given by $\Delta V \simeq \frac{f_T f_S^9}{M_{\text{Pl}}^6}$. This leads to a difference in the potential between the degenerate vacua by this amount ΔV . This energy difference leads to decay of the domain walls with a lifetime for the domain walls to be, (following [84]), $t_{\text{decay}} \sim \frac{\sigma_W}{\Delta V}$ (here σ_W is the energy per unit area in the wall and is given by $\sigma_W \sim 9m_a f_a^2$ [85, 86]). We must require that $t_{\text{decay}} \leq t_{\text{BBN}}$ to maintain the success of BBN. Also in this model the

domain walls dominate the energy density of the universe at $t_{DW} \simeq \frac{M_P^2}{8\pi\sigma_{DW}}$ and we must also demand that $t_{decay} \leq t_{DW}$ not to alter the course of big bang evolution.

Let us try to see if in this model, the constraint $t_{decay} \leq t_{BBN}$ and $t_{decay} \leq t_{DW}$ are satisfied. For this, we choose $f_S = f_T$, taking $f_a \simeq 10^{10}$ GeV. We get $t_{decay} \sim 10^{-2}$ seconds. This therefore satisfies the constraint that domain walls do not affect BBN. Similarly, for the same choice of parameters, we get $t_{DW} \simeq 10^3$ sec. satisfying the requirement $t_{decay} \leq t_{DW}$.
