# <span id="page-0-1"></span>AdvAnchor: Enhancing Diffusion Model Unlearning with Adversarial Anchors

Mengnan Zhao, Lihe Zhang, Xingyi Yang, Tianhang Zheng, Baocai Yin

# Abstract

*Security concerns surrounding text-to-image diffusion models have driven researchers to unlearn inappropriate concepts through fine-tuning. Recent fine-tuning methods typically align the prediction distributions of unsafe prompts with those of predefined text anchors. However, these techniques exhibit a considerable performance trade-off between eliminating undesirable concepts and preserving other concepts. In this paper, we systematically analyze the impact of diverse text anchors on unlearning performance. Guided by this analysis, we propose AdvAnchor, a novel approach that generates adversarial anchors to alleviate the trade-off issue. These adversarial anchors are crafted to closely resemble the embeddings of undesirable concepts to maintain overall model performance, while selectively excluding defining attributes of these concepts for effective erasure. Extensive experiments demonstrate that AdvAnchor outperforms state-of-the-art methods. Our code is publicly available at* [https://anonymous.4open.](https://anonymous.4open.science/r/AdvAnchor) [science/r/AdvAnchor](https://anonymous.4open.science/r/AdvAnchor)*.*

# 1. Introduction

Text-guided diffusion models (DMs) have garnered significant interest in the research community for their ability to generate high-fidelity images [\[14,](#page-8-0) [39\]](#page-9-0) and their widespread applications like medical image reconstruction [\[20,](#page-8-1) [42\]](#page-9-1), creative arts [\[24\]](#page-8-2), and material generation [\[2,](#page-8-3) [22,](#page-8-4) [43\]](#page-9-2). However, these models also encounter critical security concerns, such as harmful content generation [\[30\]](#page-9-3) and potential copyright infringement [\[34\]](#page-9-4). Furthermore, retraining safe DMs is challenging due to the extensive data cleaning, the high training resource consumption, and the unpredictable effects of training data on model predictions.

To remove unsafe behaviors from DMs without retraining, researchers are increasingly exploring Machine Unlearning (MU) techniques. A prominent MU approach directly fine-tunes the weights of pre-trained DMs [\[8\]](#page-8-5), often by minimizing the prediction differences between text anchors (pre-defined target prompts) and prompts containing unsafe concepts [\[9,](#page-8-6) [44\]](#page-9-5). For instance, to erase the '*Van Gogh*' style, Abconcept [\[23\]](#page-8-7) adjusts the cross-attention

<span id="page-0-0"></span>

Figure 1. Overview of the proposed AdvAnchor. To construct adversarial anchors, tiny adversarial perturbations that greatly affect the generation performance of DMs on '*Van Gogh*' are added to the embeddings of '*Van Gogh*'.  $\theta_{op}$  is fine-tuned by aligning the prediction distributions of  $e_{\text{ori}}$  with those of  $e_{\text{anchor}}$ .

module weights in DMs to enhance prediction consistency between predefined prompt pairs, such as "A picture of a painting" and "A picture of a *Van Gogh's* painting".

While recent MU methods effectively erase undesirable concepts from pre-trained DMs, they often significantly compromise the overall generation quality of models. For instance, after erasing the '*Cezanne*' style with Abconcept, the model struggles to yield images in the styles of '*Van Gogh*' or '*Picasso*'. Inspired by prior works [\[8,](#page-8-5) [21\]](#page-8-8) that utilize different anchors to fine-tune model weights, we naturally raise a key question: *How does anchor selection influence DM unlearning, and could performance be enhanced through improved anchor crafting?*

To answer this question, we conduct a systematic experimental analysis on the impact of anchors in DM unlearning. Our findings have twofold: 1) Anchors that closely resemble the undesirable concept are more effective in preserving overall model performance; 2) Effective erasure occurs when anchors omit the defining attributes of the undesirable concept. Namely, for effective erasure with minimal impact on model performance, ideal anchors should approximate the undesirable concept yet exclude its defining attributes.

Based on our analyses and prior studies (tiny adversar-

<span id="page-1-2"></span>ial perturbations can substantially affect model predictions [\[10,](#page-8-9) [48\]](#page-9-6)), we introduce AdvAnchor, a simple yet effective adversarial anchoring method for DMs. AdvAnchor creates adversarial anchors by adding crafted universal perturbations to the embeddings of undesirable concepts. These perturbations, guided by the proposed similarity losses and optimization strategies, aim to degrade the generation quality of undesirable concepts across any visual input, thereby removing defining attributes of these concepts. Notably, the adversarial anchors are versatile and can be integrated into various MU techniques, such as the alignment mechanism in Abconcept. The AdvAnchor pipeline is shown in Fig. [1.](#page-0-0)

Our contributions are three-fold: (1) We conduct a systematic analysis of anchor impact on DM unlearning, revealing that for effective concept erasure with minimal impact on model performance, ideal anchors should maintain semantic similarity to the undesirable concept while excluding its defining attributes. (2) Based on this insight, we propose AdvAnchor, a simple yet effective method that generates adversarial anchors using designed loss constraints and optimization strategies. (3) Extensive experiments demonstrate that AdvAnchor significantly enhances both erasure and preservation performance in DM unlearning.

## 2. Related work

Recent advancements in text-to-image generation [\[31,](#page-9-7) [50\]](#page-9-8), especially with the emergence of DMs [\[32,](#page-9-9) [33\]](#page-9-10), have drastically improved the quality of high-resolution image generation [\[19,](#page-8-10) [37\]](#page-9-11). However, these developments also raise security issues [\[38\]](#page-9-12), such as the dissemination of NSFW materials [\[25,](#page-8-11) [40\]](#page-9-13) and copyright infringement [\[36\]](#page-9-14). To mitigate these risks, the MU fine-tuning technique [\[4,](#page-8-12) [7,](#page-8-13) [11\]](#page-8-14) has been proposed to eliminate specific concepts from pretrained models. In this work, we focus on the DM unlearning task. Figure [2](#page-1-0) illustrates the denoising process in textguided DMs, which consists of two-steps: introducing noise to convert the data distribution into a Gaussian distribution, followed by denoising to restore the original distribution.

Several advanced MU techniques have been developed for DMs. For instance, Forget-Me-Not [\[44\]](#page-9-5) eliminates undesirable concepts by decreasing the attention map values associated with these concepts. GEOM [\[25\]](#page-8-11) introduces implicit concept erasure, focusing on removing concepts that cannot be controlled through pre-defined text prompts. P4D [\[6\]](#page-8-15) and UnlearnDiff [\[46\]](#page-9-15) evaluate the robustness of unlearning approaches by generating adversarial text prompts [\[47\]](#page-9-16). Receler [\[18\]](#page-8-16) improves the erasing robustness by introducing an adversarial learning strategy, *i.e.*, expanding the training data with adversarial soft prompts.

Particularly, depending on whether the network structure is modified, DM unlearning techniques can be categorized into adaptor-based and adaptor-free approaches. The former modifies the DM structure by introducing adaptor lay-

<span id="page-1-0"></span>

Figure 2. The denoising process of text-guided DMs. a) the encoder converts the input noise into latent representations  $x_T$ ; b) the denoiser iteratively removes the predicted noise  $\epsilon_{t\in[1,N]}$  from latent representations  $x_t^c$ ; c) the decoder reconstructs the image from the denoised representations  $x_0^c$ .

ers, learning only their weights. For instance, SPM [\[27\]](#page-8-17) constructs lightweight one-dimensional adapters [\[6,](#page-8-15) [29\]](#page-8-18) and MACE [\[26\]](#page-8-19) integrates multiple non-interfering LoRA modules [\[17\]](#page-8-20). In contrast, the latter directly updates the module weights in original DMs. For example, ESD [\[8\]](#page-8-5) and Abconcept [\[23\]](#page-8-7) fine-tune cross-attention modules, while SepME [\[49\]](#page-9-17) restricts weight modifications to image-independent layers. Our approach follows the adaptor-free paradigm, *i.e.*, fine-tuning the cross-attention modules of DMs.

In this paradigm, researchers generally align the prediction distributions for undesirable concepts with those for predefined anchors. For instance, SDD [\[21\]](#page-8-8) employs an empty prompt as the anchor for all undesirable concepts. Abconcept utilizes broader concepts compared to undesirable concepts as anchors. ESD uses both the undesirable concept and the empty prompt to create anchors. UCE [\[9\]](#page-8-6) generates anchors based on a weighted combination of various text prompts, aiming to address generation bias. Allbut-one [\[15\]](#page-8-21) presents a Prompt-to-Prompt erasing technique that employs the highest and lowest embedding values of target prompts [\[5\]](#page-8-22) to construct anchors. Unlike these methods that combine predefined text prompts to build anchors, this paper systematically explores the anchor impact on unlearning performance and introduces adversarial anchors.

## 3. Proposed method

In this section, we first explore the impact of anchors on DM unlearning. Then, we introduce the proposed AdvAnchor.

### 3.1. Impact of various anchors on DM unlearning

We follow previous unlearning approaches  $[8, 21]$  $[8, 21]$  $[8, 21]$  to conduct this research, *i.e.*, the undesirable concept  $c<sub>u</sub>$  is erased from DMs by minimizing the prediction difference between  $p_u$  and  $p_{\text{anchor}}$ . Here,  $p_u$  is a prompt containing  $c_u$  and  $p_{\text{anchor}}$ denotes a target prompt.

<span id="page-1-1"></span>
$$
\min_{\boldsymbol{\theta}_{op}} \mathcal{L}_{op} = ||f_{de}(\boldsymbol{x}_t, \boldsymbol{e}_{pu}; \boldsymbol{\theta}_{op}) - f_{de}(\boldsymbol{x}_t, \boldsymbol{e}_{anchor}; \boldsymbol{\theta}_{ori})||_2, (1)
$$

where  $\theta_{op}$  denotes the optimizable model weights for unlearning.  $f_{\text{de}}(\cdot)$  means the denoiser in Fig. [2.](#page-1-0)  $x_t$  represents

<span id="page-2-3"></span><span id="page-2-1"></span>

Figure 3. Impact of using various types of words as anchors  $(p_{\text{anchor}}^{\text{word}})$  on DM unlearning.

the latent representations of inputs at the timestamp  $t$ , which can be obtained through either the diffusion process [\[8\]](#page-8-5) or the sampling process [\[23\]](#page-8-7).  $e_{\text{pu}}$  and  $e_{\text{anchor}}$  are text embeddings of prompts  $p_u$  and  $p_{\text{anchor}}$ , respectively.  $\theta_{\text{ori}}$  refers to the fixed weights of original models.  $\|\cdot\|_2$  is the  $\ell_2$  norm.

## 3.1.1. Anchors

We use various types of  $p_u$  and  $p_{\text{anchor}}$ , detailed as follows:

1) Each anchor is designated as a word, denoted  $p_{\text{anchor}}^{\text{word}}$ , with  $p_u = c_u$ . ChatGPT [\[1\]](#page-7-0) is used to determine the anchor for  $c<sub>u</sub>$ , with potential input prompts structured as follows:

- *The closest type to* c*u*;
- *The type imitated by* c*u*;
- *The parent class of* c*u*;
- *The type least similar to* c*u*.

2) We embed  $p_{\text{anchor}}^{\text{word}}$  and  $c_{\text{u}}$  into a masked sentence to construct  $p_{\text{anchor}}^{\text{mask}}$  and  $p_{\text{u}}$ , respectively. For instance, when removing an artist style from DMs,  $p_{\text{anchor}}^{\text{mask}}$  and  $p_{\text{u}}$  can be denoted as "*A picture of a* {p *word anchor*}*'s painting*" and "*A picture of a* {c*u*}*'s painting*", respectively.

3) We prepend a same long sentence to  $p_{\text{anchor}}^{\text{word}}$  and  $c_{\text{u}}$ , to construct  $p_{\text{anchor}}^{\text{long}}$  and  $p_{\text{u}}$ , respectively. For example, when erasing the '*Van Gogh*' style, the prompt for ChatGPT to generate this long sentence might be:

- *Provide a long sentence that describes an artistic style except for 'Van Gogh'*.

4) We utilize a descriptive sentence as an anchor, called as  $p_{\text{anchor}}^{\text{desc}}$ , and  $p_{\text{u}} = c_{\text{u}}$ . For instance, when erasing an object

category, the prompt for ChatGPT may be

p<sup>desc\_1</sup>: Provide a sentence that describes the morpho*logical features of* p *word anchor. This sentence should include the common attributes between* p *word anchor and* c*u*.

p desc 2 anchor: {p desc 1 anchor}, *while excluding defining features of* c*u*.

### <span id="page-2-2"></span>3.1.2. Settings

*Evaluation metrics.* 1) We use Fréchet Inception Distance (FID) [\[13\]](#page-8-23) to measure the distance between images generated with the undesirable concept and the corresponding anchor; 2) Accuracy (ACC): For object classification, we use a pre-trained ResNet50 [\[12\]](#page-8-24). For style classification, we finetune the fully connected layer of a pre-trained ResNet18 [\[12\]](#page-8-24) on a dataset generated by original DMs. This dataset includes a blank prompt and nine artist styles: *Cezanne, Van Gogh, Picasso, Jackson Pollock, Caravaggio, Keith Haring, Kelly McKernan, Tyler Edlin*, and *Kilian Eng*.

*Evaluation data.* 1) Erasure: Generate 1,000 images per undesirable concept, with 200 seeds per concept and 5 images per seed. 2) Object preservation: Generate 1,859 images with prompts from 1,000 categories in the ImageNet dataset<sup>[1](#page-2-0)</sup>. 3) Style preservation: Generate 2,000 images with the retained styles as prompts (excluding the erased one), with 50 seeds per style and 5 images per seed.

*Others.* Under identical settings, models from multiple fine-tuning processes exhibit notable performance variation.

<span id="page-2-0"></span><sup>1</sup><https://github.com/rohitgandikota/erasing>

<span id="page-3-3"></span><span id="page-3-0"></span>

Figure 4. Ablation studies on the length of the shared sentence between  $p_{\text{anchor}}$  and  $p_u$  in DM unlearning.

Hence, we report the average evaluation results over three independent fine-tuning runs for each undesirable concept.

#### 3.1.3. Observations

The observations are as follows:

- -o1 A higher similarity between  $p_{\text{anchor}}^{\text{word}}$  and  $c_{\text{u}}$  often results in better preservation performance, as shown in Fig. [3.](#page-2-1)
- -o2 A longer shared sentence between  $p_{\text{anchor}}$  and  $p_{\text{u}}$  generally leads to better preservation performance, as demonstrated in Fig. [4,](#page-3-0) which compares the results for  $p_{\text{anchor}}$  set to  $p_{\text{anchor}}^{\text{word}}, p_{\text{anchor}}^{\text{mask}}, \text{ and } p_{\text{anchor}}^{\text{long}}.$
- -o3 Unlearning with  $p_{\text{anchor}}^{\text{desc-2}}$  usually achieves superior erasure and preservation performance than other variants, as illustrated in Fig. [5.](#page-4-0)

Additional experiments supporting these observations are provided in the Appendix. We can conclude that:

- *To preserve overall model performance,* e*anchor and* e*pu should retain high similarity (Observations o1 and o2)*.
- *Undesirable concepts can be erased by excluding their defining attributes from anchors (Observation o3).*

## 3.2. Proposed AdvAnchor

Inspired by prior studies that tiny adversarial perturbations can significantly affect model predictions [\[28,](#page-8-25) [41\]](#page-9-18), and by our conclusions, we propose AdvAnchor to generate adversarial anchors for DM unlearning.

Specifically, as the text space is discrete, AdvAnchor fine-tunes the undesirable concept  $c<sub>u</sub>$  in the embedding space to generate adversarial anchors  $e_{\text{anchor}}^{\text{adv}}$ . The *i*-th feature element of  $e_{\text{anchor}}^{\text{adv}}$  is expressed as

$$
e_{\text{anchor},i}^{\text{adv}} = \left\{ \begin{array}{rcl} e_{\text{pu},i} + e_{\text{adv}} & \text{if } e_{\text{pu},i} = e_{\text{u}} \\ e_{\text{pu},i} & \text{otherwise,} \end{array} \right.
$$

where  $e_{\text{pu}}$  and  $e_{\text{u}}$  denote the text embeddings of  $p_{\text{u}}$  and  $c_{\text{u}}$ , respectively. Since  $e_u$  remains fixed during erasure, we designate  $e_{\text{adv}}$  as a universal perturbation.

To exclude defining attributes of undesirable concepts from  $e_{\text{anchor}}^{\text{adv}}$ , given the ground truth images  $x_{gt}$  of undesirable concepts and the random noise  $z$ , we produce  $e_{\text{adv}}$  by

<span id="page-3-1"></span>
$$
\max_{\boldsymbol{e}_{\text{adv}}} \| f_{\text{DM}}(\boldsymbol{z}, \boldsymbol{e}_{\text{anchor}}^{\text{adv}}; \boldsymbol{\theta}_{\text{ori}}) - \boldsymbol{x}_{\text{gt}} \|_{2}, \tag{2}
$$

where  $f_{DM}$  denotes a pre-trained DM with fixed weights  $\theta_{\text{ori}}$ . Eq. [\(2\)](#page-3-1) aims to degrade the generation quality of undesirable concepts across any visual input. To influence the full denoising process with  $e_{adv}$ , we reformulate Eq. [\(2\)](#page-3-1) as:

<span id="page-3-2"></span>
$$
\max_{\mathbf{e}_{adv}}[\mathcal{L}_{adv}(f_{de}(\boldsymbol{x}_t, \boldsymbol{e}_{anchor}^{adv}; \boldsymbol{\theta}_{ori}), f_{de}(\boldsymbol{x}_t, \boldsymbol{e}_{pu}; \boldsymbol{\theta}_{ori}))],
$$
 (3)

where  $f_{\text{de}}(x_t, e_{\text{pu}}; \theta_{\text{ori}})$  acts as the pseudo target. We design two functions for  $\mathcal{L}_{\text{adv}}$ :  $\mathcal{L}_{\text{adv1}}$ , which measures the cosine similarity between model predictions for  $e_{\text{anchor}}^{\text{adv}}$  and  $e_{\text{pu}}$ ,

$$
\max_{\boldsymbol{e}_{\text{adv}}}[-\cos(f_{\text{de}}(\boldsymbol{x}_{t},\boldsymbol{e}_{\text{anchor}}^{\text{adv}},\boldsymbol{\theta}_{\text{ori}}),f_{\text{de}}(\boldsymbol{x}_{t},\boldsymbol{e}_{\text{pu}},\boldsymbol{\theta}_{\text{ori}}))],
$$

<span id="page-4-1"></span><span id="page-4-0"></span>

Figure 5. Comparative experiments using  $p_{\text{anchor}}^{\text{word}}$  and  $p_{\text{anchor}}^{\text{desc}}$ .

and  $\mathcal{L}_{\text{adv2}}$ , which measures the similarity between generation changes  $g_c(\cdot)$  caused by  $e_{\text{anchor}}^{\text{adv}}$  and  $e_{\text{pu}}$ :

$$
\max_{\mathbf{e}_{\text{adv}}}[-\cos(g_c(\mathbf{e}_{\text{anchor}}^{\text{adv}}), g_c(\mathbf{e}_{\text{pu}}))],
$$
  

$$
g_c(\mathbf{e}) = f_{\text{de}}(\mathbf{x}_t, \mathbf{e}, \mathbf{\theta}_{\text{ori}}) - f_{\text{de}}(\mathbf{x}_t, \mathbf{e}_{\emptyset}, \mathbf{\theta}_{\text{ori}}).
$$

Inspired by vector orthogonality, we set  $\mathcal{L}_{adv}(\cdot) = 0$  as the stopping criterion for optimizing  $e_{\text{adv}}$ . The generated  $e_{\text{anchor}}^{\text{adv}}$  can be easily integrated into various unlearning techniques by replacing predefined anchors, such as  $e<sub>anchor</sub>$  in Eq. [\(1\)](#page-1-1). Furthermore, we design alternating, sequential, and cyclical optimization strategies to update  $\theta_{op}$  and  $e_{adv}$ :

- *Alternating optimization:* We *alternately* update  $e_{adv}$  and  $\theta_{\rm op}$  with various inputs. For each input  $x_t$ , we stop optimizing  $e_{\text{adv}}$  in Eq. [\(3\)](#page-3-2) when  $\mathcal{L}_{\text{adv}}(\cdot) = 0$ , and then finetune  $\theta_{op}$  using the current  $e_{adv}$  and  $x_t$ .
- *Sequential optimization:* We first construct the final  $e_{\text{adv}}$ using various inputs, and then fine-tune  $\theta_{op}$  with the final eadv across these inputs. Each input is *repeatedly* used to update  $e_{\text{adv}}$  until the stopping criterion is met.
- *Cyclical optimization:* In contrast to sequential optimization, each input is revisited in *cycles* to update  $e_{adv}$  until the stopping criterion is met.

Algorithm [1](#page-5-0) presents the details of AdvAnchor using the alternating optimization strategy.

## 4. Experiments

## 4.1. Experimental Details

Following existing works  $[8, 21]$  $[8, 21]$  $[8, 21]$ , we conduct experiments using Stable Diffusion [\[33\]](#page-9-10). By default, we utilize the stable-diffusion-v-1-4 version. The Adam optimizer is used with a learning rate of 1e-5 for optimizing  $\theta_{op}$ , and 1e-4 for adjusting  $e_{\text{adv}}$ . For constructing adversarial anchors, we apply the alternating optimization strategy with a maximum of 30 iterations ( $S = 30$ ). For DM unlearning, only the cross-attention module weights are fine-tuned, with the unlearning step set to 50, requiring two RTX 3090 GPUs.  $\lambda$ is set to 10. The evaluation metrics include FID, ACC, and Learned Perceptual Image Patch Similarity (LPIPS) [\[45\]](#page-9-19).

## 4.2. Unlearning Evaluation

For style and object unlearning, we produce 250 images per evaluation concept, utilizing 50 seeds per concept and generating 5 images per seed.

Style unlearning. We evaluate various unlearning methods on nine artist styles described in Section [3.1.2,](#page-2-2) erasing each style individually and assessing preservation performance across the remaining styles.

The comparative results are shown in Tab. [1,](#page-5-1) with the following key observations: 1) AdvAnchor effectively eliminates undesirable styles. For instance, with  $\mathcal{L}_{adv1}$ , AdvAn-

<span id="page-5-2"></span><span id="page-5-1"></span>Table 1. Comparative results on style unlearning.  $c_{0\sim 8}$  represent nine artist styles in Section [3.1.2.](#page-2-2) We evaluate both erasure (FID†/ACC↓/LPIPS†) and preservation (FID↓/ACC†/LPIPS↓) performance. The red digits — digit<sub>1</sub>, digit<sub>2</sub>, and digit<sub>3</sub> — indicate the best, second-best, and third-best erasure results, respectively. Similarly, the blue digits highlight best results for preservation performance.

Algorithm 1: AdvAnchor.

<span id="page-5-0"></span>**Input:** The training dataset  $\mathcal{D}$ ; noise schedule  $\bar{\alpha_t}$ ; denoiser  $f_{\text{de}}(\cdot; \cdot)$ ; original DM weights  $\theta_{\text{ori}}$ ; optimizable weights for unlearning  $\theta_{op}$ ; maximum iteration S; and prompt  $p_u$  with undesirable concept  $c_{u}$ .  $e_{pu}$ ,  $e_{u}$ , and  $e_{\emptyset}$  are embeddings of  $p_u$ ,  $c_u$ , and  $c_{\emptyset}$ , respectively.

**Output:** The fine-tuned model weights  $\theta_{op}$ .

1 Randomly initialize a universal variable  $e_{adv}$ ;

2 for  $x_0 \in \mathcal{D}$  do

3 Randomly select a sampling step t;

 $\bm{x}_t = \sqrt{\bar{\alpha}_t} \bm{x}_0 + \sqrt{1-\bar{\alpha}_t} \bm{\epsilon}, \, \bm{\epsilon} \in \mathcal{N}(0, \mathbf{I});$ 

5  $\epsilon_{\text{pu}} = f_{\text{de}}(\boldsymbol{x}_t, \boldsymbol{e}_{\text{pu}}; \boldsymbol{\theta}_{\text{ori}}); \ \epsilon_{\emptyset} = f_{\text{de}}(\boldsymbol{x}_t, \boldsymbol{e}_{\emptyset}; \boldsymbol{\theta}_{\text{ori}});$ 

```
6 /*Generating adversarial anchors.*/
```

chor increases the average FID/LPIPS values for undesirable styles from 0/0 to 417.4/0.408, while decreasing their average ACC from 99.2 to 4.22. 2) AdvAnchor with  $\mathcal{L}_{\text{adv1}}$ shows superior erasure performance and comparable preservation performance compared to existing approaches. 3) AdvAnchor with  $\mathcal{L}_{\text{adv2}}$  exhibits optimal model preservation performance while maintaining comparable erasure effectiveness to previous techniques. 4) Erasing different styles

affects the generation quality of retained styles to varying extents. For instance, erasing the '*Cezanne*' style greatly influences the generation performance for '*Van Gogh*', '*Jackson Pollock*', and '*Caravaggio*', whereas erasing the '*Keith Haring*' style has minimal effect on retained styles. 5) The difficulty of erasing different styles also varies. For example, AdvAnchor with  $\mathcal{L}_{adv1}$  can reduce the classification accuracy of most undesirable styles to 0%. However, erasing the '*Van Gogh*' style remains challenging.

Object unlearning. We use category names from Imagenette [\[16\]](#page-8-26) as prompts to evaluate object unlearning [\[8,](#page-8-5) [21\]](#page-8-8). The '*Cassette Player*' category is excluded due to the low accuracy of the classification network on images of this category. It can be observed from Tab. [2](#page-6-0) that AdvAnchor shows excellent erasure and preservation abilities in object unlearning. Notably, in terms of preservation performance, DM unlearning affects styles more significantly than objects. For instance, using AdvAnchor with  $\mathcal{L}_{\text{adv2}}$ , the average FID for retained styles is 75.5 (see Tab. [1\)](#page-5-1), while for retained objects it is 23.8 (see Tab. [2\)](#page-6-0). Fig. [6](#page-6-1) provides visual examples illustrating the effectiveness of AdvAnchor in both object and style unlearning.

Explicit content removal. We then show the efficacy of AdvAnchor in erasing exposed content by removing the word 'nudity'. For erasure evaluation, we generate 4,073 images using unlearned DMs with I2P prompts [\[35\]](#page-9-20) and count the number of images exposing body parts. The original DM yields 815 sensitive images across 8 classes, classified by Nudenet [\[3\]](#page-8-27). To asses preservation performance, 1,859 images are produced with prompts from ImageNet.

The results are presented in Fig. [8,](#page-7-1) with the following key observations: 1) AdvAnchor with  $\mathcal{L}_{\text{adv1}}$  outperforms  $\mathcal{L}_{\text{adv2}}$  in erasing exposed content, likely due to the higher initial value of  $\mathcal{L}_{\text{adv1}}$ , which strengthens the adversarial anchors. 2) Compared to other methods, AdvAnchor with  $\mathcal{L}_{\text{adv1}}$  achieves the optimal erasure capability and the superior preservation performance in terms of ACC, while maintaining competitive FID and LPIPS scores. Visual examples of AdvAnchor on 'nudity' unlearning are shown in Fig. [7.](#page-6-2)

Unlearning other I2P categories. Using I2P categories

<span id="page-6-3"></span><span id="page-6-0"></span>Table 2. Comparative results on object unlearning. c0∼<sup>9</sup> represent the object categories '*Chain Saw', 'Church', 'Gas Pump', 'Tench', 'Garbage Truck', 'English Springer', 'Golf Ball', 'Parachute', 'French Horn'*, respectively. We evaluate both erasure (FID†/ACC↓/LPIPS†) and preservation (FID↓/ACC†/LPIPS↓) performance. The red digits — digit<sub>1</sub>, digit<sub>2</sub>, and digit<sub>3</sub> — indicate the best, second-best, and third-best erasure results, respectively. Similarly, the blue digits highlight best results for preservation performance.

Figure 6. Visual examples of AdvAnchor in style (top two rows) and object (bottom two rows) unlearning.

as prompts, we train an 8-class classifier with a pre-trained ResNet18: seven unsafe classes from I2P (1,000 samples for each class) and one safe class (7,000 ImageNet samples), achieving 92.8% classification accuracy. Preservation performance is evaluated using ImageNet prompts. The results presented in Tab. [3](#page-7-2) show that AdvAnchor achieves optimal performance in both erasure and preservation.

Others. For explicit content removal, the Appendix presents ablation studies that incorporate various unsafe categories from NudeNet, rather than relying solely on the term 'nudity.' Moreover, the Appendix includes experiments conducted on other versions of Stable Diffusion, and across various tasks such as facial identity unlearning.

## 4.3. Ablation Studies

Impact of optimization strategy on AdvAnchor: We compare different optimization strategies for nudity un-

<span id="page-7-3"></span>Table 4. Ablation study on optimization strategies in AdvAnchor. We report average metric values over three runs. 'Erasure' indicates the count of images exposing body parts, while 'Preservation' includes  $FID\downarrow$ /ACC $\uparrow$ /LPIPS $\downarrow$  as evaluation metrics.  $S = 40$ .

sults are presented in Tab. [5.](#page-7-4) For AdvAnchor with  $\mathcal{L}_{\text{adv1}}$ , increasing S notably improves erasure performance but reduces preservation performance. In contrast, modifying S has minimal effect on AdvAnchor with  $\mathcal{L}_{\text{adv2}}$ , as  $\mathcal{L}_{\text{adv2}}$ quickly meets the stopping criterion, making further adjustments to S largely ineffective.

# 5. Conclusions

In this paper, we address the performance trade-off issue in DM unlearning by exploring the influence of anchor selection. Our analysis reveals that ideal anchors should exclude defining attributes specific to undesirable concepts while re<span id="page-7-4"></span>Table 5. Ablation study on hyperparameter S. We report average metric values over three runs. 'Erasure' indicates the count of images exposing body parts, while 'Preservation' includes FID↓/ACC↑/LPIPS↓ as evaluation metrics.

maining close to these concepts. To this end, we propose AdvAnchor, which yields adversarial anchors using specifically designed loss constraints and optimization strategies. Experimental results demonstrate that AdvAnchor effectively removes undesirable concepts while preserving the generative quality of DMs for retained concepts.
