We study the effects of imperfect nesting in a simple 2D tight-binding model on the electronic properties in the density-wave (DW) state. The discussed model reflects the main features of quasi-1D metals where the DW emerges. We show that an imperfect nesting leads to unusual singularities in the quasi-particle density of states, leading to a strong renormalization of the superconducting critical temperature. We also compute the conductivity tensor of the normal state and obtain a satisfactory agreement with the experimental data on rare-earth tritellurides and many other DW materials.

I. INTRODUCTION

The interplay between superconductivity (SC) and charge or spin density wave (DW) attracts a vast research activity. The SC-DW competition and coexistence appears in various strongly-correlated electron systems, including the high-temperature cuprate [1–6] and iron-based [7–10] superconductors, NbSe₂ [11–13] and other rare-earth di- and poly-chalcogenides [14, 15], various organic superconductors [16–24], and many other materials (see, e.g., Refs. [25–27] for reviews).

The DW in metals creates a spatial modulation of the charge or spin density of conducting electrons with the wave vector Q and opens a gap Δ_0 on the Fermi level in the electronic spectrum, which lows the electron energy [28]. Depending on the electron dispersion $\epsilon(\mathbf{k})$ in this metal, two different DW states are possible. The first one, called the perfect nesting of the Fermi surface (FS), happens when $\epsilon(\mathbf{k}) + \epsilon(\mathbf{k} + \mathbf{Q}) < \Delta_0$ for all \mathbf{k} at the FS. Then the DW covers the entire FS and the metal becomes a semiconductor in a DW state. In this case a uniform SC on a DW background is hardly possible, but SC may appear via a spatial segregation with DW, as happens in various materials [22, 24, 29–31]. This SC heterogeneity can be visualized by the scanning tunneling microscopy (STM) and spectroscopy [29, 32–40], by the local diamagnetic probe [41, 42], or detected and analyzed using the resistivity anisotropy measurements [43–48]. The spatial DW-SC phase segregation usually appears on a large length scale, greater than the DW coherence length $\xi_{DW} = \hbar v_F/(\pi \Delta)$, as it happens in organic superconductors [22, 24, 47], or on the microscopic scale, i.e. in the form of DW soliton walls [49–51].

The second scenario of DW-SC coexistence appears in the case of imperfect FS nesting when $\epsilon(\mathbf{k}) + \epsilon(\mathbf{k} + \mathbf{Q}) > \Delta_0$ for some \mathbf{k} at the FS. In this case the metallic conductivity survives in a DW state till $T \to 0$, being anisotropically reduced, e.g., as in various rare-earth three-chalcogenides [52] and many other materials [25–28]. One could expect an exponential decrease of the superconducting transition temperature T_c on the DW

background even in the imperfect-nesting case, because according to the BCS theory in the weak-coupling regime

$$T_c \sim \omega_D \exp(-1/g\nu_F)$$
 (1)

exponentially depends on the electron density of states (DoS) at the Fermi level ν_F multiplied by the coupling constant g, with the Debye frequency ω_D in the preexponential factor. As the DW opens a gap at least on some parts of FS, the DoS ν_F is reduced by the DW, leading to a destructive SC-DW interference [53, 54]. However, usually, one has a more complicated SC-DW interplay: the superconducting transition temperature T_c is the highest at the quantum critical point (QCP) where the density wave (DW) get suppressed by some external parameter, such as doping level [1–6], pressure [7–10, 16– 22], cooling rate [23, 24], disorder [12], etc. The T_c domelike shape near the DW QCP results from the enhancement of electron-electron (e-e) interaction $g \to g_*(\mathbf{Q})$ in the Cooper channel by the critical DW fluctuations, which can be described as the SC vertex renormalization in the language of Feynman diagram technique [55, 56]. Note that this vertex renormalization changes its momentum dependence and may favor the unconventional superconductivity [57–59].

Below we consider only the second scenario of the uniform DW in the case of imperfect nesting. What is stronger, the SC coupling renormalization $g \to g_*(\mathbf{Q})$ or the DoS reduction $\nu_F \to \nu_{F*}$ by the DW? This question is very important for the SC transition temperature in the weak-coupling regime given by Eq. (1). According to the theoretical calculations [55–58] the SC coupling enhancement $g \to g_*(\mathbf{Q})$ is not very strong, especially far from the DW QCP, when the DW order parameter Δ is larger than the SC energy gap. On contrary, the gapped FS area in the DW state is, usually, rather large, as visualized by ARPES measurements in various compounds [60–70]. How the observed increase of T_c on the DW background, implying the increase of the product $q\nu_F$, is then possible?

The insight resolving this apparent inconsistency is proposed in Ref. [71] where the electronic DoS in the

DW state with slightly imperfect nesting is calculated in the mean-field approximation and shown to be unexpectedly large at the Fermi level even if the ungapped FS pockets are very small. This happens because of the strong renormalization of electron spectrum by the DW. Hence, T_c on the DW background, taking into account the coupling-constant renormalization $g \to g_*(\mathbf{Q})$, can be even larger than the SC transition temperature T_{c0} without DW. The calculations in Ref. [71] are limited by the very small ungapped FS pockets and are performed under some approximations about the electron dispersion.

In this paper we generalize these calculations of the DoS on the DW background for the case of arbitrary imperfect nesting, when the size of ungapped FS parts may be large. Although the main goal of our calculations is to estimate the change of SC transition temperature by the DW background, our results are useful also for other electronic properties of DW compounds, even without superconductivity. For example, the DoS enters the electronic part of specific heat and other thermodynamic and transport electron properties, which can be measured.

II. MODEL

The DW state usually appears in strongly anisotropic quasi-1D metals because of their good FS nesting [27, 28, 72. In many other DW compounds there is a hidden quasi-one-dimensionality, although their electronic transport exhibits a 2D isotropy along the conducting layers. An example of such a hidden quasi-1D electron spectrum are the rare-earth tritellurides [52, 73] or tetratellurides [74, 75], where the FS consists of two pairs of perpendicular quasi-1D warped sheets originating from the Te p_x and p_y orbitals, giving almost tetragonal symmetry of electronic properties, broken by the CDW [52]. Of course, there are some DW materials with closed quasi-2D rather than open quasi-1D FS, but even they have some nearly flat FS parts, such as transition metal dichalcogenides [76] or high-Tc cuprates [66, 77]. Below we consider quasi-1D metals as a quite generic system bearing the DW.

In layered quasi-2D metals due to crystal periodicity the electron dispersion is given by the Fourier series

$$\varepsilon(\mathbf{k}) = -2t_x \cos(ak_x) - 2t_y \cos(bk_y)$$

$$-\sum_{i,j\geq 2} 2t_{ij} \cos(ak_x i) \cos(bk_y j),$$
(2)

where a and b are the lattice constants in x and y directions. The tunneling amplitude along the z axis is considerably smaller than that along the conducting layers x,y and is discarded, as it does not play any role in the analysis below. Usually, the last term in Eq. (2) is much smaller than the first two and is also omitted, corresponding to the tight-binding model [78, 79].

In quasi-1D metals, where the x-axis represents an easy-conducting chain direction and $t_x \gg t_y$, it is often

FIG. 1. The electron spectrum $E(k_x, k_y)$ given by Eq. (3) and shown by yellow surface. The FS (two Fermi wavy curves in the $k_x - k_y$ plane) is formed by the intersection of this spectrum with the horizontal plane of fixed electron energy equal to the chemical potential or Fermi energy.

convenient to linearize the k_x electron dispersion near the Fermi level. Then the free-electron dispersion without magnetic field can be written as [27, 71, 80, 81]

$$\varepsilon(\mathbf{k}) = v_{\mathrm{F}}(|k_x| - k_F) - 2t_y \cos(bk_y) - 2t_y' \cos(2bk_y), \tag{3}$$

where b is the lattice constant in y direction and the first term represents the electron dispersion along the x-direction linearized near the Fermi surface. Even if all $t_{ij}=0$ in Eq. (2), $t_y'\sim t_y^2/t_x\neq 0$ and comes from the nonlinearity of electron dispersion along the x-direction. We drop all the other hopping amplitudes in y - direction, as they are small by the parameter $t_y/t_x\ll 1$.

Without the last antinesting t'_y term in Eq. (3) the perfect nesting condition

$$\varepsilon(\mathbf{k}) + \varepsilon(\mathbf{k} + \mathbf{Q}) = 0 \tag{4}$$

is satisfied at wave vector $\mathbf{Q}=(2k_{\mathrm{F}},\pi/b)$ (see Fig. 1). The electron spectra and FS near k_{F} and $-k_{\mathrm{F}}$ are nested with the nesting vector \mathbf{Q} . The outlined quasi-1D system exhibits the charge-density wave (CDW) formation as the result of a nesting-driven Fermi surface instability. This leads to the opening of gap Δ in the quasiparticle spectrum. However, this simple picture undergoes a dramatic change once we take into account the antinesting amplitude t'_{ν} .

Although in quasi-1D metals $t_y' \sim t_y^2/t_x \ll t_y$, the retained term t_y' rather than t_y competes with the energy gap Δ in the resulting ground state equations. The $2t_y'$ term in (3) is called "antinesting" because it violates the nesting condition (4). In what follows, we discard the possible influence of t_y' on the nesting vector \mathbf{Q} and discuss the legitimacy of this approach in section IV.

As seen from Fig. (1), the FS consists of two warped unconnected curves separated by vector Q. This allows to us to split the quasiparticle Fock's space into two disconnected parts corresponding to the neighborhood of each Fermi sheet

$$\psi(\mathbf{r}) = \sum_{\mathbf{k} \in U(\mathbf{k}_F)} a(\mathbf{k}) e^{i\mathbf{k}\mathbf{r}} + \sum_{\mathbf{k} \in U(-\mathbf{k}_F)} a(\mathbf{k}) e^{i\mathbf{k}\mathbf{r}}$$

$$\equiv \sum_{\mathbf{k}} a_1(\mathbf{k}) e^{i\mathbf{k}\mathbf{r}} + \sum_{\mathbf{k}} a_2(\mathbf{k}) e^{-i\mathbf{k}\mathbf{r}}$$
(5)

As usually in Peierls's transition physics, we assume that the deformation of the lattice has a static nature. The lattice deformation potential mixes two different parts (see Eq. (5)) of the Fock's space and adds one more term in the Hamiltonian. Accordingly, the electron Hamiltonian can be written as follows

$$\hat{H} = \hat{H}_0 + \hat{H}_{\text{int}} \tag{6}$$

with the free-electron part in momentum representation being

$$\hat{H}_0 = \sum_{\mathbf{k}} a_1^{\dagger}(\mathbf{k}) a_1(\mathbf{k}) \varepsilon(\mathbf{k}) + \sum_{\mathbf{k}} a_2^{\dagger}(\mathbf{k}) a_2(\mathbf{k}) \varepsilon(\mathbf{Q} + \mathbf{k}).$$
 (7)

and the electron-lattice interaction part given by

$$\hat{H}_{\text{int}} = \Delta \sum_{\mathbf{k}} \left(a_1(\mathbf{k}) a_2^{\dagger}(\mathbf{k}) + a_1^{\dagger}(\mathbf{k}) a_2(\mathbf{k}) \right), \quad (8)$$

where Δ is proportional to the amplitude of lattice deformation. In the physics of the Peierls transition $\Delta \equiv \Delta(T)$ becomes the temperature-dependent gap of the quasiparticle spectrum.

Diagonalization of the Hamiltonian (6) leads to the standard gapped spectrum

$$E(\mathbf{k}) = \frac{\epsilon(\mathbf{k}) + \epsilon(\mathbf{k} + \mathbf{Q})}{2} \pm \sqrt{\frac{(\epsilon(\mathbf{k}) - \epsilon(\mathbf{k} + \mathbf{Q}))^2}{4} + \Delta^2}.$$
(9)

Substituting Eq. (3) to Eq. (9) we obtain the following quasiparticle spectrum in the presence of the CDW

$$E(k_x, k_y) = -2t_y' \cos 2k_y \pm \sqrt{(k_x v_F - t_y \cos k_y)^2 + \Delta^2}.$$
(10)

We illustrate this quasiparticle spectrum in Fig. (2).

III. CALCULATIONS AND RESULTS

A. Quasiparticle DOS

To understand the behavior of the transport properties of the system we need to compute the single particle density of states (DOS)

$$\nu(\varepsilon) = \sum_{\mathbf{k}} \delta(\varepsilon - E(\mathbf{k})) \equiv \int \delta(\varepsilon - E(\mathbf{k})) \, \frac{dk_x dk_y}{(2\pi)^2}, \quad (11)$$

where $\delta(x)$ is the Dirac δ -function. Integration is performed over the Brillouin zone. Due to the symmetry of gapped spectrum (9) the integration region can be reduced to the quarter of the Brillouin zone. After the integration over q_x the expression (11) becomes

$$\nu(\varepsilon) = \frac{1}{\pi^2 v_F} \int_{0}^{\pi/2} \frac{|\varepsilon + \Delta_1 \cos 2q_y b|}{\sqrt{(\varepsilon + \Delta_1 \cos 2q_y b)^2 - \Delta^2}} dq_y \quad (12)$$

with the notation $\Delta_1 \equiv 2t_y'$ introduced for convenience. Although the integral (12) can only be evaluated numerically (see Fig. 3), one can obtain analytical results in some regions where the DOS reveals intriguing (singular) behavior. These cases are discussed in the next subsection.

B. The behavior of DOS near singularities

The DOS is an even function of energy as can be easily checked from expression (12). This function has two singularities. The jump at point $\Delta_1 - \Delta$ and the divergence at point $\Delta_1 + \Delta$ correspond to the appearance and the merger of the closed pockets on the surface of fixed energy (see Fig. 2).

The singularities in the DOS are seen from the structure of the integrand in Eq. (12). Namely, we see that the square root in the denominator of the integrand of (12) has the branch points at energy $\varepsilon = \Delta \pm \Delta_1$ where the pockets of the constant energy surface start to merge, as in Fig. (2) (b). The corresponding analytical expression for the DOS near the threshold energy $\Delta + \Delta_1$ reads:

$$\nu(\Delta + \Delta_1 + \delta \varepsilon) = \frac{1}{\pi^2 v_{\rm F} b} \left[2 \arcsin \sqrt{\frac{\Delta_1}{\Delta + \Delta_1}} + \sqrt{\frac{\Delta}{4\Delta_1}} \left(\ln \frac{32\Delta}{\Delta_1 + \Delta} - \ln \frac{\delta \epsilon}{\Delta_1} \right) \right].$$
(13)

As we see from Eq. (13), the DOS has a logarithmic singularity at the threshold energy $\varepsilon = \Delta + \Delta_1$, where it coincides with the sum of the CDW gap Δ and the antinesting parameter Δ_1 . This corrects and generalizes the qualitative analysis presented in Ref. [71] (Fig. 3), where the log-singularity was predicted at $\varepsilon = \Delta$ instead of $\Delta + \Delta_1$.

There exists another threshold $\varepsilon = \Delta_1 - \Delta$. We need to address two possible situations: $\Delta < \Delta_1$ and $\Delta > \Delta_1$. We have the following results for the DOS (see Appendix

FIG. 2. (a) The quasiparticle spectrum (yellow) in the presence of a CDW with $\Delta_1 = 0.8\Delta$. The green plane corresponds to the constant energy cross section $\varepsilon = \Delta_1 \equiv 2t_y'$. The closed pocketsare clearly seen as green puddles above the yellow surface. (b) The spectrum of the quasiparticles in the presence of the CDW. The green plane corresponds to the position of the constant energy cross section, the antinesting $\Delta_1 = 1.5\Delta$ and the energy level $\varepsilon = \Delta + \Delta_1$, where Δ is the Peierls energy gap. The critical energy at which the DOS manifests log divergence.

FIG. 3. Comparison of the numerical DOS (blue curve) with analytical results (orange curve). The singularities of the function are clearly seen. At point $A = \Delta_1 - \Delta$ DOS function has a jump (Eq. (14a)) and at point $B = \Delta_1 + \Delta$, DOS has a logarithmic divergence (Eq. (13)). We used $\Delta = 1(a.u.)$ is the Peierls energy gap and $\Delta_1 = 1.3(a.u.)$ is the the antinesting term.

A):

$$\nu(\Delta_{1} - \Delta + \delta\varepsilon) = \frac{1}{2\pi v_{F}b} \Big[\Big[1 - f(\delta\varepsilon) \Big] + f(\delta\varepsilon)\theta(-\delta\varepsilon) \Big], \quad \Delta < \Delta_{1} \quad (14a)$$

$$\nu(\Delta - \Delta_{1} + \delta\varepsilon) = \frac{1}{2\pi v_{F}b} f(-\delta\varepsilon)\theta(\delta\varepsilon), \quad \Delta > \Delta_{1} \quad (14b)$$

$$f(\delta\varepsilon) = \frac{1}{2} \sqrt{\frac{\Delta}{\Delta_{1}}} - \frac{\delta\varepsilon}{16} \sqrt{\frac{\Delta}{\Delta_{1}}} \frac{3\Delta_{1} + \Delta}{\Delta_{1}},$$

The resulting graph, juxtaposing the analytical formulas (13)-(14b) in the vicinity of singularities and numerical

computation of (12) are presented in fig. (3).

C. Tc temperature

Now we analyze how the discussed above singular behavior of DOS and the antinesting term affect the superconducting transition temperature T_c on DW background.

The equation for T_c is given by the BCS integral [78]

$$\frac{2}{g} = 2 \int_0^{\omega_D} \frac{d\xi}{\xi} \tanh \frac{\xi}{2T_c} \nu(\xi), \tag{15}$$

where g is the electron-phonon coupling constant in the BCS theory and ω_D is the cutoff at Debye frequency. The Eq. (15) reproduces the corresponding integral derived from the linearized Gor'kov equations for superconductivity on the DW background [71, 82]).

We perform the calculation at Debye frequency $\omega_D < \Delta_1 + \Delta$. i.e. the integration domain doesn't include the log-singularity of the DOS. This can be the case in e.g. rare earth tellurides ($\sim 170~\rm K)[83]$, where $\omega_D \sim 0.015~\rm eV$. The superconductive gap is assumed to vanish, since we position ourselves just above the transition temperature. In this case the integration (15) can be performed analytically with the help of expression (14a). We obtain the following analytical result for T_c :

$$T_c = \left(\frac{\omega_D}{\Delta_1 - \Delta}\right)^{-\frac{\delta\nu}{\nu}} T_0,$$

$$T_0 = \omega_D e^{-\frac{1}{\nu g}}, \ \nu = \frac{1}{\pi v_F b}, \ \delta\nu = \frac{1}{\pi v_F b} \sqrt{\frac{\Delta}{\Delta_1}}$$
 (16)

We expectedly reproduced the nonanalytic exponential ν - dependence of the T_c . However, we also see an interesting change in the pre-exponential part. This is precisely where the antinesting term in the initial Hamiltonian (3) comes on stage. The comparison of the analytical result (16) with numerical calculation of integral (15) is presented in Fig. 4. Formulae (16) and the plot in Fig. 4 are the main physical results of this section.

FIG. 4. Comparison of the numerical T_c (blue curve) with analytical result (16) (orange curve), where Δ_1 is the antinesting term and Δ is the Peierls energy gap. The dashed part of the analytical curve corresponds to the region $\Delta_1 - \Delta \lesssim T_c$ where the analytical relation (16) doesn't work.

IV. CONDUCTIVITY

In this section we present the computation of conductivity given by the integral obtained from the Kubo' formula in the DW state described within the mean-field approximation

$$\sigma_{ij} = -\int \frac{d\varepsilon}{2\pi} \frac{\partial f(\varepsilon)}{\partial \varepsilon} \int \frac{d^2 \mathbf{k}}{(2\pi)^2} v_i(\mathbf{k}) v_j(\mathbf{k}) G^A(\varepsilon, \mathbf{k}) G^R(\varepsilon, \mathbf{k}),$$
(17)

where $f(\varepsilon)$ is the Fermi distribution function and $v_i(\mathbf{k}) \equiv \nabla_{k_i} E(\mathbf{k})$ is *i*th component of the velocity vector operator (see Eq.10).

The impurity-electron scattering rate is given by the imaginary part of the quasiparticle Green's function self-energy:

$$\frac{1}{2\tau} = \pi n_{imp} \int \delta(E(\mathbf{k})) \frac{d^2 \mathbf{k}}{(2\pi)^2} = \pi n_{imp} g^2 \nu(0).$$
 (18)

Integrating (17) over energy ε , yields the following expressions for conductivity tensor:

$$\sigma_{xx}(T) = \frac{\tau}{2T} \int \xi(\mathbf{k}, T) \frac{d\mathbf{k}}{(2\pi)^2}$$

$$\sigma_{yy}(T) = \frac{\tau}{2T} \int [2t_y \sin bp_y]^2 \xi(\mathbf{k}, T) \frac{d\mathbf{k}}{(2\pi)^2},$$
(19)

with

$$\xi(\mathbf{k}, T) = \frac{1}{4 \cosh^2 \frac{E(\mathbf{k}, T)}{2T}} \frac{(v_F k_x - t_y \cos b k_y)^2}{(v_F p_x - t_y \cos b k_y)^2 + \Delta^2(T)}.$$
(20)

The temperature dependence of the Peierls gap Δ is taken in the mean-field approximation and Landau theory of the second-order phase transition as:

$$\Delta(T) = \Delta_0 \sqrt{1 - \frac{T}{T_c}}. (21)$$

Next, we need to keep in mind that apart from impurity scattering there is an additional contribution to the electron scattering rate from electron-phonon interaction, the full scattering rate being the algebraic sum of the impurity and phonon scattering.

As is known, the electron-phonon interaction is described by the Bloch-Gruneisen law [79]

$$\frac{1}{\tau} = A \cdot F\left(\frac{\theta_D}{T}\right),$$

$$F(z) = \int_0^z \frac{z^5 dz}{(e^z - 1)(1 - e^{-z})}.$$
(22)

Here the constant A contains the sound velocity, the ion mass and Debye temperature θ_D .

FIG. 5. Numerical resistivity $1/\sigma_{xx}$ (blue curve) and $1/\sigma_{yy}$ (orange curve) as a functions of temperature. Parameter A entering the scattering rate (22) is taken such that the residual resistance ratio parameter for σ_{xx} is ≈ 70 .

Numerical integration of Eq. (19) and the resultant conductivities are presented in Fig. (5). To perform calculations, we took realistic DW parameters [52] $\Delta_0 = 0.27$ eV, $T_c = 0.03$ eV, $t_y = 0.37$ eV, $t_y' = 0.16$ eV. Our results presented by plots in Fig. 5 demonstrate a qualitative consistency with the experimental data obtained in paper [52] and with numerous other experimental curves [27, 28]. This is the second main result of our paper.

V. DISCUSSION

We studied the influence of the CDW with arbitrarily imperfect nesting on the critical temperature of the superconducting transition for the general model of a realistic quasi-1D metal. We have discovered that the imperfect nesting manifests itself in the strong renormalization of the preexponential factor in the dependence of BCS critical temperature on the electron DOS.

The discussed renormalization comes from the change in the electron dispersion and in the FS geometry due to the antinesting term t'_{y} in the Hamiltonian (3).

Here, the following important remark is in order. In the main body of the paper we completely discarded the influence of the antinesting term t_y' on the nesting vector \mathbf{Q} . Now we need to elaborate on this. Strictly speaking, at finite t_y' the Fermi surface looses the perfect nesting property. Inevitably, the question arises if the ideal nesting vector $Q = (2k_F, \pi/b)$ can be used as a principal vector for the CDW formation. One could even ask if the introduction of such a vector was still meaningful in the absence of the FS nesting. The meaning of \mathbf{Q} in the absence of ideal nesting is indeed different. It should be interpreted as the displacement vector that maximizes the Kubo susceptibility

$$\chi(T, \mathbf{Q}) = -\int \frac{d\mathbf{k}}{(2\pi)^2} \frac{n_{\mathrm{F}}(\mathbf{k} - \mathbf{Q}, T) - n_{\mathrm{F}}(\mathbf{k}, T)}{\epsilon(\mathbf{k} - \mathbf{Q}) - \epsilon(\mathbf{k})}, \quad (23)$$

since the condition of the Peierls transition corresponds to the equation $\chi(\mathbf{Q}) = g^{-1}$, where g is the electron-phonon coupling constant and $n_{\mathrm{F}}(\mathbf{k},T)$ is the Fermi distribution function. Taking a realistic temperature T=100K, we computed the displacement $\delta\mathbf{Q}$ of the CDW wave vector. Our calculation gives $\delta Q_x/Q_x \approx -0.02$ and $\delta Q_y/Q_y \approx -0.2$ in a reasonable agreement with earlier calculations. The corresponding numerical plot of the DoS, where the correct displacement vector \mathbf{Q} is taken into account, is presented in Fig. 6. As we see from Fig. 6, the positions of singularities and the quantitative shape of the curve are not significantly affected by the change of the nesting vector $\delta\mathbf{Q}$. This way one sees that for not too large antinesting term, the contribution to the DOS form the change of Q is negligible.

Finally, the temperature dependence of the conductivity tensor is analyzed in the framework of our model. We show that the nontrivial DOS leads to qualitative agreement of our results and the experimental data in rare-earth tritellurides [52] and in many other DW compounds [27, 28].

Appendix A: DOS with imperfect nesting

From now on we put $v_{\rm F}=1$, b=1 restoring them in the final formulae. In this section we investigate the imperfect nesting case. The dispersion (3) doesn't satisfy the perfect nesting condition $\varepsilon(\mathbf{k}) + \varepsilon(\mathbf{k} + \mathbf{Q}) \sim 0$. Therefore, accordingly (3) the spectrum for quasiparticles (9) has the following view:

$$E(q_y) = \frac{-4t_y' \cos 2q_y}{2} \pm \sqrt{\frac{(2q_x - 2t_y \cos q_y)^2}{4} + \Delta^2},$$
(A1)

with

$$q_x = k_x - k_F, \ q_y = k_y \tag{A2}$$

In all following calculations, the region of integration is the quarter of the Brillouin zone due to the symmetry of the gapped spectrum (A1).

Let us first, assume that the anti nesting term is not small and satisfies the condition:

$$2t_{u}^{'} = \Delta_{1} > \Delta. \tag{A3}$$

The DOS is possible to compute analytically in the vicinity of $\Delta + \Delta_1$: $\epsilon = \Delta + \Delta_1 + \delta \epsilon$, $\delta \epsilon \ll \Delta$. After integrating over q_x integral (11) becomes as follows:

$$2\int_0^{\pi} \frac{\Delta + \delta\epsilon + \Delta_1(1 + \cos 2q_y)}{\sqrt{(\Delta + \delta\epsilon + \Delta_1(1 + \cos 2q_y))^2 - \Delta^2}} \frac{dq_y}{(2\pi)^2}. \quad (A4)$$

Subtracting singular terms, we obtain:

$$2\int_{0}^{\pi} \left[\frac{b + 2\cos^{2}q_{y}}{\sqrt{(b + 2\cos^{2}q_{y})^{2} - b^{2}}} - \sqrt{\frac{b}{4}} \frac{1}{|\cos q_{y}|} \right] \frac{dq_{y}}{(2\pi)^{2}} + 2\sqrt{\frac{b}{2}} \int_{0}^{\pi} \frac{1}{\sqrt{2\cos^{2}q_{y} + a}} \frac{dq_{y}}{(2\pi)^{2}},$$

$$b = \frac{\Delta}{\Delta_{1}}, \ a = \frac{\delta\epsilon}{\Delta_{1}}. \tag{A5}$$

The first part of the integral (A5) can be taken easily with the substitution:

$$t = \cos q_y, \ dq_y = \frac{1}{\sqrt{1 - t^2}}$$
 (A6)

$$2\int_{0}^{\pi} \left[\frac{b + 2\cos^{2}q_{y}}{\sqrt{(b + 2\cos^{2}q_{y})^{2} - b^{2}}} - \sqrt{\frac{b}{4}} \frac{1}{|\cos q_{y}|} \right] \frac{dq_{y}}{(2\pi)^{2}} =$$

$$= \int_{0}^{1} \left[\frac{2t}{\sqrt{1 - t^{2}}\sqrt{b + t^{2}}} + \frac{b - \sqrt{b^{2} + bt^{2}}}{t\sqrt{b + t^{2}}\sqrt{1 - t^{2}}} \right] \frac{dt}{(2\pi)^{2}} =$$

$$\frac{1}{(2\pi)^{2}} \int_{0}^{1} \frac{dt}{t\sqrt{1 - t^{2}}} \left[\frac{b + 2t^{2}}{\sqrt{b + t^{2}}} - \sqrt{b} \right] =$$

$$\frac{1}{2\pi^{2}} \left[\arcsin \frac{1}{\sqrt{1 + b}} - \frac{\sqrt{b}}{2} \ln \left(1 + \frac{1}{b} \right) \right].$$
(A7)

The second part of the integral (A5) is

$$\frac{2}{(2\pi)^2} \sqrt{\frac{b}{2}} \int_0^{\frac{\pi}{2}} \frac{ds}{\sqrt{2\sin^2 s + a}} = \frac{2}{(2\pi)^2} \sqrt{\frac{b}{2}} \left[\int_0^{\frac{\pi}{2}} \left(\frac{ds}{\sqrt{2}\sin s} - \frac{ds}{\sqrt{2}s} \right) + \int_0^{\frac{\pi}{2}} \frac{ds}{\sqrt{2s^2 + a}} \right] = \frac{\sqrt{b}}{(2\pi)^2} \left(\ln 4\sqrt{2} - \ln \sqrt{a} \right)$$

$$s = q_y - \frac{\pi}{2}, \frac{s}{q_y} \ll 1. \tag{A8}$$

Summarizing (A7) and (A8), we have the final form of the DOS in the main body of the paper (13).

Now let's suppose that $\varepsilon = \Delta_1 - \Delta + \delta \varepsilon$, $\delta \varepsilon \ll \Delta$. Two different occasions are here. If $\delta \varepsilon > 0$ or $\delta \varepsilon = 0$ pockets have not yet appeared and the integral (12) is

$$\int_0^{\arccos\sqrt{b+\frac{a}{2}}} \frac{a-b+2\cos^2 q_y}{\sqrt{(a-b+2\cos^2 q_y)^2-b^2}} \frac{dq_y}{(2\pi)^2},$$

$$b = \frac{\Delta}{\Delta_1}, \ a = \frac{\delta\varepsilon}{\Delta_1}. \tag{A9}$$

When $\delta \varepsilon = 0$ it is nice to use the substitution $t = \cos q_y$:

$$\int_{0}^{\arccos\sqrt{b}} \frac{-b + 2\cos^{2}q_{y}}{\sqrt{(-b + 2\cos^{2}q_{y})^{2} - b^{2}}} \frac{dq_{y}}{(2\pi)^{2}} =$$

$$\int_{0}^{\arccos\sqrt{b}} \frac{2\cos^{2}q_{y} - b}{2\sqrt{(\cos^{2}q_{y} - b)(\cos^{2}q_{y})}} \frac{dq_{y}}{(2\pi)^{2}} =$$

$$\int_{\sqrt{b}}^{1} \frac{2t^{2} - b}{2t\sqrt{(t^{2} - b)}\sqrt{1 - t^{2}}} \frac{dt}{(2\pi)^{2}} = \frac{1}{8\pi} \left(1 - \frac{\sqrt{b}}{2}\right). \tag{A10}$$

When $\delta \varepsilon < 0$, two small pockets appear in the area of the point $q_y = \pi/2$. Consequently, pockets make a contribution in the DOS:

$$\int_{\frac{\pi}{2} - \arccos\frac{\sqrt{a}}{2}}^{\frac{\pi}{2}} \frac{a - b + 2\cos^{2}q_{y}}{\sqrt{(a - 2b + 2\cos^{2}q_{y})(a + 2\cos^{2}q_{y})}} \frac{dq_{y}}{(2\pi)^{2}} = \int_{0}^{\arcsin\frac{\sqrt{|a|}}{2}} \frac{-|a| - b + 2\sin^{2}s}{\sqrt{(-|a| - 2b + 2\sin^{2}s)(-|a| + 2\sin^{2}s)}} \frac{ds}{(2\pi)^{2}},$$

$$s = q_{y} - \frac{\pi}{2}, \frac{s}{q_{y}} \ll 1. \tag{A11}$$

Next, we expand $\sin s$ and $\arcsin \frac{\sqrt{|a|}}{2}$ over small parameters:

$$\int_{0}^{\sqrt{\frac{|a|}{2}}} \frac{-|a| - b + 2s^{2}}{\sqrt{(-|a| - 2b + 2s^{2})(-|a| + 2s^{2})}} \frac{ds}{(2\pi)^{2}} = \int_{0}^{\sqrt{\frac{|a|}{2}}} \frac{-b}{\sqrt{2b(|a| - 2s^{2})}} \frac{ds}{(2\pi)^{2}} = -\sqrt{b} \frac{1}{16\pi}.$$
 (A12)

Finally, combining Eq. (A10) and Eq. (A12) we obtain an equation for the density of states (14a) Now let us calculate the DOS with the energy $\varepsilon = \Delta - \Delta_1 + \delta \epsilon$, $\Delta > \Delta_1$. The integral of DOS (12) is

$$\int_{0}^{\pi/2} \frac{a + \frac{b}{2} - \sin q_{y}^{2}}{\sqrt{(a + b - \sin q_{y}^{2})(a - \sin q_{y}^{2})}} \frac{dq_{y}}{(2\pi)^{2}},$$

$$a = \frac{\delta \epsilon}{2\Delta_{1}}, \ b = \frac{\Delta}{\Delta_{1}}, \ \sin q_{y} = a \sin t. \tag{A13}$$

The completely analogous calculations yield Eq. 14b.

Appendix B: SC critical temperature

Using equation for T_c (15):

$$\frac{2}{g} = 2 \int_0^{\omega_D} \frac{d\xi}{\xi} \tanh \frac{\xi}{2T_c} \nu(\xi)$$
 (B1)

The r.h.s. can be represented as the sum of simple integrals, where we use the step-like structure of the density

of states, presented in (14a), (14b).

$$\frac{1}{g} = \nu \int_{T_c}^{\Delta_1 - \Delta} \frac{dx}{x} + (\nu - \delta \nu) \int_{\Delta_1 - \Delta}^{\omega_D} \frac{dx}{x} = \nu \ln \left(\frac{\Delta_1 - \Delta}{T_c}\right) + (\nu - \delta \nu) \ln \left(\frac{\omega_D}{\Delta_1 - \Delta}\right) = \nu \ln \frac{\omega_D}{T_c} - \delta \nu \ln \frac{\omega_D}{\Delta_1 - \Delta}.$$
(B2)

The equation over T_c (B2) is solved and gives

$$T_c = \omega_D \left(\frac{\omega_D}{\Delta_1 - \Delta}\right)^{-\frac{\delta\nu}{\nu}} e^{-\frac{1}{\nu g}},$$

$$\nu = \frac{1}{\pi v_F b}, \ \delta\nu = \frac{1}{\pi v_F b} \sqrt{\frac{\Delta}{\Delta_1}}.$$
(B3)

Appendix C: Conductivity

The integral (17) is computed with complex analysis. Combination of Green functions

$$G^{A}(\varepsilon, \mathbf{k})G^{R}(\varepsilon, \mathbf{k}) = \frac{1}{(\varepsilon - E(\mathbf{k}))^{2} + (\frac{1}{2\tau})^{2}}$$
(C1)

can be substituted with the Dirac δ -function $\delta\left(\varepsilon - E(\mathbf{k})\right)$ in the limit $\frac{1}{\tau} \ll \varepsilon - E(\mathbf{k})$:

$$G^{A}(\varepsilon, \mathbf{k})G^{R}(\varepsilon, \mathbf{k}) \approx \tau \delta \left(\varepsilon - E(\mathbf{k})\right).$$
 (C2)

After integrating over ε , Eq.(17) simplifies to

$$\sigma_{ij}(T) = \frac{\tau}{2T} \int \frac{d\mathbf{k}}{(2\pi)^2} \frac{1}{4\cosh^2 \frac{E(\mathbf{k},T)}{2T}} \frac{\partial E(\mathbf{k})}{\partial r_i} \frac{\partial E(\mathbf{k})}{\partial r_j}.$$
(C3)

From the last equation we obtain the final Eqs. (19) presented in the main body.
