## Abstract

This White Paper documents the discussion and consensus conclusions of the workshop "Software Infrastructure for Advanced Nuclear Physics Computing" (SANPC 24), which was held at Jefferson Lab on June 20–22, 2024. The workshop brought together members of the US Nuclear Physics community with data scientists and funding agency representatives to discuss the challenges and opportunities in advanced computing for Nuclear Physics in the coming decade. Opportunities for sustainable support and growth are identified within the context of existing and currently planned DOE and NSF programs.

<sup>&</sup>lt;sup>a</sup> Corresponding Author: pmjacobs@lbl.gov

## I. NOTE TO THE NUCLEAR PHYSICS COMMUNITY

This is the first public draft of a White Paper summarizing the discussions and conclusions of the Workshop on Software Infrastructure for Advanced Nuclear Physics Computing that was held at Jefferson Lab on June 20–22, 2024 (SANPC24). The workshop brought together members of the US Nuclear Physics community with data scientists and funding agency representatives, to discuss the challenges and opportunities in advanced computing for Nuclear Physics in the coming decade.

The purpose of this White Paper is to present the consensus achieved at the workshop, identifying opportunities for future directions and the strengthening of current efforts. While the workshop attendees represented the breadth of the NP community, not everyone with interest and something to say on these matters could attend and contribute to the content of the current White Paper draft.

We are therefore requesting comment and input from the entire NP community on all aspects of this White Paper draft. We will collect community comments though Friday February 14, 5 pm PST.. After incorporating changes from this input, we will post the final White Paper on the arXiv.

Please send comments to the corresponding author, Peter Jacobs (pmjacobs@lbl.gov). Suggestions for changes to text are welcome, including corrections and additions. Concerning Sect. VI ("Opportunities"), note that this document should not make prescriptive recommendations to the funding agencies - its goal is rather to identify opportunities from the community perspective.

We look forward to your input.

White Paper Writing Committee Jan. 2, 2025

## **II. EXECUTIVE SUMMARY**

Software, computing, and ever-larger datasets have become key drivers of Nuclear Physics (NP) research, due to explosive growth in scientific facilities, algorithms, and exascale capacity. The 2023 Long Range Plan (LRP) for Nuclear Science emphasized the importance of capitalizing on these extraordinary opportunities for scientific discovery, identifying the investment in emerging technologies, advanced computing, and multidisciplinary centers as a high priority for the field of Nuclear Physics.

A range of federal agency programs, including the DOE Scientific Discovery through Advance Computing (SciDAC) program, the NSF Cyberinfrastructure for Sustained Scientific Innovation (CSSI) program, and DOE Exascale Computing Project (ECP), have successfully supported multi-disciplinary collaborations of nuclear scientists, computational scientists, and applied mathematicians to meet this challenge. These collaborations have enabled scientific advances and software innovation. Such alliances continue to be essential for tackling nuclear physics problems at the forefront with innovative approaches, including the adoption of industry developments and best practices.

As the next step in realizing the vision for advanced computing expressed in the LRP, a workshop entitled *Software Infrastructure for Advanced Nuclear Physics Computing* (SANPC 24) was held at Jefferson Lab on June 20-24, 2024. This White Paper presents the discussion and consensus of the workshop participants about critical research directions, challenges, and opportunities for sustainable support and growth, to realize the LRP vision. Workshop attendees represented all sub-areas of the US Nuclear Physics portfolio. The Workshop organization and agenda are found in the Appendix.

The primary observations and opportunities identified at the workshop for support of the software infrastructure needed for groundbreaking advances in Nuclear Physics are as follows:

**Innovation** Sustainable software infrastructure for nuclear physics discovery requires innovation in hardware and algorithmic developments, and the inclusion of approaches and best practices from industry. Such innovations are often implemented in common software ecosystems that have broad application in the NP research portfolio. The importance of these ecosystems will increase as they incorporate further innovations in AI/ML and other rapidly developing technologies. **Cross-cutting initiatives** The NP research enterprise has benefited greatly from multidisciplinary efforts, which drive innovation by incorporating developments in computational science, applied mathematics, statistics, and from emerging industries. Sustainable support mechanisms are needed for such multi-disciplinary collaborations, with flexibility to support projects of widely varying scale.

**Stewardship** It is vital that funding instruments enable continuity and evolution of community software and software infrastructure. Sustained support in these areas leverages current investments and promotes software functionality on new HPC and other novel hardware systems. Effective stewardship should cover the full lifecycle of data and software management.

**Data curation and preservation** To maximize the return on current investments in NP facilities and instruments, forward-looking data analysis and preservation are essential. The development of robust mechanisms for long–term preservation of data and associated metadata, which include research software and workflows, is needed to ensure long-term accessibility and reproducibility of publicly–funded science.

Workforce Forefront NP research frequently depends upon high–performance computing and large–scale data analysis. Retention of an expert workforce in this area requires sustained funding support and viable career paths for scientific software developers working at the intersection of nuclear physics, data science, and computing. Retention mechanisms include mentorship programs, training opportunities, and the recognition of software contributions as integral to scientific research.

#### III. INTRODUCTION

Software and computing have become drivers in Nuclear Physics (NP), due to the explosive growth of scientific data and exascale facilities. Exploitation of these opportunities requires new hardware architectures and new algorithmic approaches at exascale, including those based on Artificial Intelligence and Machine Learning.

New collaborative efforts have emerged to capitalize on these opportunities, bringing NP theorists and experimentalists together with data and computer scientists. A common theme of such collaborative efforts is the development of robust, large-scale software infrastructure frameworks to carry out their complex scientific programs. While these frameworks require long-term support, the establishment of suitable support mechanisms for that purpose is challenging. The curation and long-term preservation of data and associated analysis tools is an important related issue.

The 2023 Long Range Plan of the Nuclear Science Advisory Committee (NSAC LRP) [1] incorporates a vision of the future of advanced computing for NP research. A workshop entitled "Software Infrastructure for Advanced Nuclear Physics Computing" (SANPC) [2] was held at Jefferson Lab on June 20–22, 2024, bringing together NP computing practitioners to discuss the implementation of this vision, with a focus on identifying mechanisms to achieve long-term, sustainable software infrastructure. The workshop program covered a broad range of current software and computing projects in the NP domain. Discussions addressed the role of research vs. infrastructure software, development of common software ecosystems, software sustainability best practices, and workforce development. Existing and currently planned DOE and NSF programs which support advanced NP computing and cyber-infrastructure were reviewed.

This White Paper presents the workshop discussion and consensus about critical research directions, challenges, and opportunities for Advanced Computing in Nuclear Physics. Additional material can be found in the slides of the workshop presentations [3].

## IV. CURRENT LANDSCAPE

This section provides context for the workshop discussion in terms of current funding instruments and coordinating organizations, grant-funded projects, and general considerations for the major NP sub-areas. Additional workshop presentations on selected topics are also described.

#### A. Funding instruments

Sustained funding for the core effort in advanced computing in NP is provided by the Nuclear Physics program in the DOE Office of Science [4] and the Division of Physics in the Mathematical and Physical Sciences directorate of the National Science Foundation [5]. Additional funding by time-limited grants is provided by various agencies, as follows.

## 1. ASCR

The mission of the Advanced Scientific Computing Research program (ASCR) [6] is to develop, deploy, and utilize US high–performance computational and networking capabilities to analyze, model, simulate, and predict complex phenomena. Special emphasis is placed on emerging computing systems and novel computing architectures.

ASCR has recently launched a new partnership with the NNSA and the Linux Foundation under the High Performance Software Foundation (HPSF) [7], which is aligned with the ASCR mission to support High-Performance Computing (HPC) systems. HPSF aims to build, promote, and advance a portable software stack for HPC systems by increasing adoption, lowering barriers to contribution, and supporting development efforts.

Additional seed projects [8] have been constituted to develop a sustainable software ecosystem for Post-Exascale Computing (PEC), organized under the umbrella of the Consortium for the Advancement of Scientific Software [9]: Collaboration for Better Software [10]; Center for Open-Source Research Software Advancement [11]; Partnering for Scientific-Software Ecosystem Opportunities [12]; Stewardship for Programming Systems and Tools [13]; Software Tools Ecosystem Project [14]; and Stewardship and Advancement of Workflows and Application Services [15].

#### 2. SciDAC

The SciDAC program (Scientific Discovery Through Advanced Computing, [16]) supports R&D in supercomputing software and hardware infrastructure for scientific discovery. SciDAC is a partnership of six DOE Office of Science programs: Advanced Scientific Computing Research; Basic Energy Sciences; Biological and Environmental Research; Fusion Energy Sciences; and High-Energy Physics and Nuclear Physics; together with the Office of Nuclear Energy. SciDAC fosters cross-disciplinary collaboration of applied mathematicians, computer scientists, and domain scientists. Support for these parterships is provided by the FASTMath [17] and RAPIDS [18] SciDAC Institutes.

SciDAC is the most significant funding mechanism for NP projects in multi-disciplinary partnerships. SciDAC project support is structured in five-year funding cycles, with the current funding cycle (FY21-25) focused on AI/ML and exascale science.

#### 3. CSSI/NSF

The Cyberinfrastructure for Sustained Scientific Innovation program (CSSI) [19] of the National Science Foundation supports multi-disciplinary (multi-directorate) projects in the development of cyberinfrastructure (CI), emphasizing integrated CI services, quantitative metrics of delivery and usage, and community creation. There are three classes of awards:

- Elements: small-group awards for the creation and deployment of services for a targeted need.
- Framework Implementation: larger, interdisciplinary team awards to develop and apply services supporting a broad research area in the NSF science and engineering portfolio, providing a sustainable software framework to a diverse community.
- Transition to Sustainability: awards for groups to provide sustained support of existing CI that will impact a broad research area in the NSF science and engineering portfolio, using new methodologies.

Support for Elements and Frameworks is of finite duration, up to 10 years. NSF funding is generally only available to university groups.

## 4. DNN/NNSA

The mission of the Office of Defense Nuclear Nonproliferation (DNN) [20], an agency in the DOE National Nuclear Security Administration (NNSA) [21], is the prevention of state and non-state actors from developing nuclear weapons or acquiring weapons-usable nuclear or radiological materials, equipment, technology, and expertise.

Data science is a key element of the DNN research portfolio. DNN supports R&D in data analysis and AI to detect, locate, and characterize foreign nuclear weapon development activities, and to support nuclear security. Current research areas include decision-making under uncertainty and AI/ML-assisted discovery, which require the modeling of complex systems, measurements with sparse and noisy data, and reliable detection of rare events. These challenges drive investment in AI technologies such as foundational models, knowledge graphs, and AI agents, and benchmarking for testing and evaluation.

The DNN mission is defined by national security needs. A handful of dual-use NP projects fall within this scope.

#### 5. Simons Foundation

The Simons Foundation Scientific Software Research Faculty Award [22] supports scientific software-focused research professor positions in existing academic programs. The goal of this award is to stimulate the development and maintenance of core scientific software infrastructure in academic environments by creating a new, long-term, faculty-level career path. The Foundation provides five years of support at 50%.

## B. Survey of term-funded projects

Advanced Computing in modern NP research covers a broad scientific scope. Projects that are formally funded by the instruments outlined in Sect. IV A play a special role in advancing the frontiers of advanced NP computing. The workshop devoted significant plenary time to surveying currently funded projects, with emphasis on their computing scope and future needs.

This section presents brief sketches of the projects discussed at the workshop. While not a complete list of all US-funded NP advanced computing projects, it provides a representative

cross-section. The interested reader should consult the workshop presentation slides [3] and project web pages for further detail.

## 1. BAND

The BAND Collaboration [23, 24] seeks to create a suite of general-purpose software tools that will enable principled Uncertainty Quantification across a wide range of NP problems, including neutrinoless double beta decay; r-process nucleosynthesis and the associated nuclear masses, and reaction and beta-decay rates; heavy-ion Collisions and inference of Quark-Gluon Plasma properties; as well as reaction dynamics and nuclear data evaluation. Significant emphasis is placed on code sustainability, code stewardship, and the reproducibility of results.

BAND is funded by the NSF CSSI program. BAND currently has 32 collaborators at 11 institutions.

## 2. ENAF

The ENAF Collaboration (Exascale Nuclear Physics for FRIB) [25] studies the production of chemical elements in astrophysical events using cutting-edge astrophysics simulations that employ state-of-the-art nuclear physics. This requires the capabilities of the most advanced supercomputers, and benefits strongly from collaboration with applied mathematicians and computer scientists. The primary focus of ENAF is the r-process in neutron star mergers. ENAF also seeks to understand the impact of neutrino flavor oscillations on this nucleosynthesis mechanism, as well as its observability in kilonovae. An essential facet of ENAF is uncertainty quantification for such nucleosynthesis predictions.

Technical challenges include high-performance GPU-based implementations of key computational kernels for thermonuclear kinetics and neutrino radiation transport computations, and ML-based inference engines designed for the interpolation of tabular astrophysics data. The maintenance of high performance on evolving HPC architectures is challenging for such multi-physics codes.

ENAF is supported by DOE/NP and ASCR through the SciDAC program. ENAF currently has 14 collaborators at 6 institutions.

#### 3. iQuS

The InQubator for Quantum Simulation (iQuS) [26] at the University of Washington carries out theoretical studies of strongly-interacting correlated matter and complex quantum systems, using quantum simulations and theoretical approaches that incorporate quantum entanglement and coherence. The iQuS scientific scope includes lattice gauge theories, spin systems, cold atoms, neutrinos, topological phases and dynamics, and hardware development. The institute currently has seven staff and three postdocs, with a workshop and visitor program carried out in conjunction with the Institute for Nuclear Theory at UW.

Error mitigation is based largely on commercial (e.g. IBM–developed) algorithms, whereas error correction has aspects unique to NP (e.g. Gauss's law check in lattice gauge theory). The hardware and software configurations which are currently available for practical use are somewhat patchwork, and improved organization is needed for significant future progress. Continued access by NP academic researchers to all quantum computer architectures is likewise vital for future progress.

#### 4. JAM

The JAM (Jefferson Lab Angular Momentum) Collaboration [27] studies the internal quark and gluon structure of hadrons by reconstructing quantum correlation functions (PDFs, FFs, TMDs, GPDs) from experiment. This inference task, corresponding to the solution of multiple layers of an inverse problem (factorization, evolution, ...), is challenging.

JAM takes a rigorous Bayesian Monte Carlo approach that computing-intensive; JAM calculations have reached the limit of computing resources available from the JLab CST Division. ML-based techniques are being explored to address this limitation, including collaboration with other projects (QGT, JLab LDRD, QuantOm) to optimize GPU hardware usage. Additional synergistic collaboration between NP and ASCR–supported projects is needed to fully meet the promise of the JLab 12 GeV program

Members of the JAM collaboration are funded by DOE and NSF grants. The collaboration is hosted at Jefferson Lab, which coordinates software development of software and provides access to its HPC systems. The collaboration includes theorists, experimentalists, and computer scientists, with 27 collaborators at 13 institutions.

## 5. JETSCAPE

The JETSCAPE Collaboration [28, 29] studies hot and cold QCD matter using a modular framework for simulating the complex dynamical environment of high–energy hadronic and nuclear collisions, and Bayesian inference for rigorous data/model comparisons. JETSCAPE focused initially on hot QCD matter and the Quark-Gluon Plasma, but more recently has expanded its scope to include the study of both QCD phase transitions and the partonic structure of nucleons and nuclei.

The Bayesian inference component of the JETSCAPE scope is computationally expensive, and is limited by the availability of HPC resources. JETSCAPE and related efforts develop and exploit ML-based approaches for emulation and likelihood evaluation, to achieve efficient resource utilization.

JETSCAPE is funded by the NSF/CSSI program. The JETSCAPE Collaboration is an interdisciplinary team of theoretical and experimental physicists, computer scientists, and statisticians, comprising about 60 collaborators from 13 institutions.

#### 6. MUSES

The MUSES Collaboration (Modular Unified Solver of the Equation of State) [30] develops cyber-infrastructure to address interdisciplinary questions in nuclear physics, gravitational wave astrophysics, and heavy-ion physics, with special focus on the QCD phase diagram and neutron stars, using tools provided by lattice and perturbative QCD, chiral effective field theory and models. MUSES creates software communities through short-term grants to academic groups for software development related to their research. Such efforts build upon existing software ecosystems, and the resulting software is free and open-source.

There are three core aspects to the MUSES cyberinfrastructure: independent software modules that calculate equations of state, calculate physical observables, and/or process data; a software framework for integration and interoperability of these modules; and the Calculation Engine, a management system to orchestrate the execution of composable, multimodule workflows. MUSES is funded by the NSF/CSSI program. MUSES is an interdisciplinary team that currently counts 134 collaborators, 25% of whom carry out software development, from about 20 institutions.

#### 7. NUCLEI

The NUCLEI Collaboration (Nuclear Computational Low-Energy Initiative) [31] carries out precise calculations, with quantified uncertainties, of stable nuclei and rare isotopes, the electroweak response of nuclei and nuclear matter, and nuclear fission. The collaboration develops and refines low-energy nuclear interactions and currents, exploiting exascale computing facilities for the modeling of atomic nuclei, their reactions, and nuclear matter. These calculations support experimental programs at FRIB, ATLAS, JLab, DUNE, and future ton-scale neutrino facilities.

NUCLEI is funded by the SciDAC program, with active participants from both RAPIDS and FASTMath. It is an interdisciplinary collaboration of physicists, computer scientists, and applied mathematicians, with 57 members at 13 institutions.

#### 8. QuantOm

The QuantOm Collaboration (QUAntum chromodynamics Nuclear TOMography) [32] develops novel approaches to the femtoscale imaging of protons and nuclei in terms of their three-dimensional quark and gluon structure. Key questions include the momentum and spatial distribution of quarks and gluons, and the dynamical generation of proton mass.

QuantOm focuses on optimizing the comparison of theoretical calculations and experimental electron-scattering measurements. Current NP and HEP published experimental data are reported as binned histograms, resulting in a significant loss of information and analysis flexibility. QuantOm is developing mechanisms for unbinned, event-wise analysis of large datasets from JLab and the future EIC, to overcome these limitations. This approach is computationally intensive, requiring exascale resources and new ML/AI tools for data storage and analysis.

QuantOm is supported by the SciDAC program. QuantOm is an interdisciplinary collaboration of QCD theorists and experimentalists, applied mathematicians, data scientists, and HPC experts. The QuantOm collaboration has 25 members from 6 institutions.

## 9. USQCD

Quantum Chromodynamics (QCD) is by its nature non-linear because the gluon, the QCD force moderator, carries color charge and interacts with other gluons. The non-linear nature of QCD results in rich phenomenology, including the confinement of quarks and gluons in hadrons. However, theoretical calculations of QCD phenomena are complex, requiring specialized approaches. For high-energy interactions, corresponding to small distance scales, the QCD coupling is small and an analytic expansion is applicable (perturbative QCD, or pQCD). However, for low-energy interactions corresponding to long distance scales, good analytic control is not achievable, and first-principles calculations must be carried out numerically on a discrete lattice (Lattice QCD, or LQCD) [33].

Current LQCD calculations cover several NP sub-areas, with strong connections to the NP and HEP experimental programs [34]:

- QCD phase structure and thermodynamics: confinement and chiral symmetry phase transitions; QCD critical point; color superconductivity; neutron star equation of state; transport in the Quark-Gluon Plasma. Synergy with the heavy-ion experimental programs at RHIC and the LHC.
- Hadron spectroscopy: hadron masses; prediction of new heavy or exotic hadrons. Synergy with the JLab and EIC experimental programs.
- Hadron structure: EM and Gravitational Form Factors; partonic structure (PDFs, TMDs, GPDs). Synergy with the JLab and EIC experimental programs.
- Fundamental Symmetries: lepton number violation; properties of the neutrino. Synergy with neutrinoless double beta decay  $(0\nu\beta\beta)$  experimental program.
- Beyond Standard Model (BSM) physics: neutrinos; dark matter; lepton flavor violation. Synergy with DUNE, HyperK, dark-matter searches, μ2e.

LQCD calculations utilize Monte Carlo sampling on a discrete space-time lattice. Calculational precision of better than 1% is required in some cases, necessitating the use of novel sampling methods to approach the continuum limit and detailed accounting of subtle QED and isospin effects. ML-based methods offer an opportunity for developing efficient new algorithms for LQCD. Calculations of atomic nuclei are especially complex since calculational cost grows rapidly with nuclear mass A.

The US LQCD community effort is coordinated by the USQCD Collaboration [35, 36], whose membership of 180 scientists comprises over 90% of all US LQCD researchers in NP and HEP. The USQCD Collaboration fosters software development and student and post-doc training, and coordinates the funding and allocation of mid-scale computing resources located at JLab, BNL, and FNAL. The US LQCD effort has been supported by SciDAC for over two decades, with contributions from NP, HEP, ASCR, and NNSA. Its support during that period totals over \$50M.

The US LQCD community has significant connections to industry, notably GPU library development (QUDA/Nvidia) and code generators for new hardware. The flow of LQCD expertise from academia to industry helps foster these connections.

## C. Advanced computing in NP experiments

While NP experimental projects receive significant funding from the DOE and NSF to support their core activities, they also require support for R&D for advanced computing that is not covered by the core funding. This section sketches the advanced computing landscape in the NP experimental research areas.

## 1. FRIB

The Facility for Rare Isotope Beams (FRIB) [37] at Michigan State University provides high-intensity beams of atomic nuclei across the periodic table over a wide range of energies, for the exploration of nuclear structure, nuclear astrophysics and the r-process, fundamental symmetries, and applied NP. FRIB hosts 1800 users from 53 countries.

The FRIB experimental program is broad, utilizing a mix of large facility-supported instruments and small user-provided equipment. Experiments are typically granted one week of beam time for specified beams and energies, with the size of recorded datasets ranging from a few GB to  $\sim 100$  TB.

Most FRIB experimental collaborations do not have dedicated software developers. The FRIB facility provides support to experimental groups for data-taking and near-online analysis capabilities, primarily by a small Scientific Software Group. This group also carries out R&D for experimental computing, in response to user requirements. The application of ML-based approaches has the potential to speed up FRIB data analysis by orders of magnitude, reducing the time to publication and enhancing the user experience. In addition to the user-facing efforts, efforts are also underway to improve FRIB operations by adopting AI/ML technologies in the accelerator division.

#### 2. JLab

The Continuous Electron Beam Accelerator Facility (CEBAF) at Jefferson Lab (JLab)[38] is a unique facility for detailed exploration of the structure of hadrons and atomic nuclei, and other aspects of QCD and the Standard Model. CEBAF hosts about 1900 users from around the world. JLab also partners with BNL for the management, design and construction of the Electron Ion Collider.

CEBAF delivers a highly polarized electron beam, with currents up to 180  $\mu$ A, to fixed targets in four experimental halls simultaneously. Beam characteristics (intensity, polarization, and energy) are tuned to optimize the physics utilization of each hall independently. Data rates from the experimental halls have risen continuously as a result of new detector and data acquisition (DAQ) capabilities, and are projected to reach 3–4 GB/sec in 2025.

Most of the data produced by JLab are stored and analyzed on-site. Currently, JLab's experimental program generates datasets on the order of 10–20 PB per year. The computing infrastructure for analysis and simulation is primarily housed within the JLab Scientific Computing facility. However, there is significant and increasing use of external resources such as the Open Science Grid (OSG) and the National Energy Research Scientific Computing Center (NERSC). Software support includes a mix of internally supported common infrastructure (DAQ, data storage management, compute workflow management, etc.) and application–specific analysis and simulation toolkits managed by the external collaborations, often with Hall support. This model works well for large collaborations, but presents an ongoing challenge for small collaborations with high personnel turnover rates.

JLab has made a significant investment in developing and delivering AI/ML supported tools, both internally and in cooperation with external collaborations. These ongoing R&D efforts are critical to take full advantage of the vast amount of data that modern detector systems provide, improving operational efficiency and reducing the time to final physics publication.

The High Performance Data Facility (HPDF)[39] launched in late 2023 will be hosted at JLab. Once operational, this unique scientific user facility will provide advanced infrastructure for data-intensive science.

#### 3. Neutrino experiments

The NP neutrino physics portfolio encompasses  $0\nu\beta\beta$  and sterile neutrino searches, and neutrino mass and scattering cross-section measurements. It has significant overlap with the HEP neutrino and dark matter programs, and with other Fundamental Symmetry efforts.

Compared to other NP sub-areas, experimental neutrino physics has a stronger emphasis on hardware and highly-customized detectors, with less emphasis on advanced computing and physics modeling. Experimentally, events are rare and require minimal on-detector data reduction. However, large-scale simulations are vital to understanding systematics and backgrounds. These models are necessarily very complex and highly tuned, leading to computational challenges. Next-generation  $0\nu\beta\beta$  search detectors project data volumes of ~ 100 TB/year (nEXO [40]) or 1 PB/year (LEGEND-1000 [41]).

Ongoing challenges in this sector include ensuring that the data sets are portable and well documented, allowing broader analysis access outside of a custom computing environment. Integration of AI/ML techniques for low-level data processing, exploration of systematics, and accelerated reconstruction shows significant promise.

#### 4. Collider experiments

Collider experiments at RHIC [42] the LHC [43], and in the future at the EIC [44], are based on large multi-purpose detectors which run many months per year, managed by collaborations whose international membership numbers in the hundreds to few thousands. The data pipeline of modern detectors is typically continuous-streaming readout, with multiple levels of on-the-fly data reduction, analysis, and event tagging.

As an example, the ALICE detector at the LHC [45] currently generates 3.4 TB/s from its readout electronics, which is reduced to less than 100 GB/s for transmission to longterm storage, corresponding to an annual recorded data volume of about 60 PB. ALICE reconstruction and analysis software consists of about 2M lines of code, managed by a core computing team of about ten people, with expert contributions from hundreds of collaborating physicists. The time interval from the recording of raw data to its availability for physics analysis is currently about one year, limited by the complexity of the data and by computing capacity in terms of CPU, data management, and storage. Computing capacity for simulations that are essential for data analysis are similarly limiting.

A collider experiment is a decades-long enterprise, requiring sustained support for computing infrastructure. This need persists after the completion of experimental running, for data preservation and re-analysis. Support for this effort is provided primarily by the host laboratory (RHIC, CERN, FNAL, etc.), which is also responsible for the retention of institutional memory and specific expertise via staffing. However, other institutions and funding agencies, beyond those supporting the host laboratory directly, typically also provide significant support for long-term software sustainability and distributed computing.

A common theme for software infrastructure in large international collaborations is the interplay between commercially-provided software solutions, publicly available open source software (e.g. GNU/GPL, CERN), and purpose-built solutions. The relative cost of the various approaches, in terms both of personnel effort and financial support, varies with time. Collaborations continuously evaluate such costs, and invest in software development to ensure long-term software functionality and to renew expertise within the collaborations. Essential software development includes both experiment-specific applications and innovative technologies, notably AI/ML and new computing hardware paradigms.

#### D. Workshop contributed talks

The workshop included an open mic session, with brief contributed talks. This section summarizes key points raised in that session about future directions in advanced computing for NP.

a. Challenges in non-equilibrium many-body dynamics (A. Bulgac) Many physical phenomena in NP involve non-equilibrium long-term dynamics, e.g. nuclear fission, Quark-Gluon Plasma evolution, quantum turbulence, many-body entanglement, fermion-antifermion production in strong fields, neutrino collective oscillations, fermionic superfluid systems, quantum transport, and non-Markovian processes. Theoretical approaches to such processes based on traditional calculational methods, which describe stationary or quasi-stationary processes, are inadequate, necessitating a qualitatively new approach.

Such calculations require HPC capability at the largest scale available, and will do so for the foreseeable future. These are long-term projects, requiring long-term code development and data storage. Funding instruments are needed to support and steward such efforts in a sustained way, including that of small research groups.

b. Machine Learning for NP applications (M. Ploskon) There are applications of ML that have the potential to be transformative in NP research, but that are not of similar importance to industry. Examples include explainable and interpretable ML (e.g. [46]) and novel data analysis architectures using graph Neural Networks.

Interdisciplinary collaboration with computational scientists has proven to be effective in addressing such problems. However, such efforts corresponds more to the application of existing ML approaches to NP problems, and less to the development of novel techniques. Current funding instruments available to NP domain scientists are on the whole not targeted at such ML applications, as opposed to more generic ML developments. However, ML applications are increasingly important to advance NP science, in both experiment and theory. A support stream for ML–related applications to advance NP science would be beneficial.

c. Open data for NP simulations (C. Shen) Bayesian inference analysis of heavy-ion collision data requires large-scale computing resources, generating large volumes of simulated data [47, 48]. Such analyses employ ML-based techniques for efficient utilization of computing capacity, and open access for community usage of expensive simulated data such as these would be highly beneficial to the field.

However, data storage is expensive, and both general access and long-term data storage require robust software solutions. As an example, there are several possible approaches to address this issue for Bayesian inference of heavy-ion data, listed here from simple to comprehensive:

- tagged version of code container and parameter data stored on the Open Science Grid. This is appropriate for model emulation in Bayesian Inference analyses.
- Particle yields and flow vectors as functions of kinematic observables for each simulated event. This is appropriate for general model emulation at the event-by-event level and is an effective way to communicate about new experimental analyses.

• All final-state hadron momentum information for each event, with end-to-end event evolution history. This is appropriate only for the most detailed analyses, and only a small fraction of the data is needed in this format.

A support stream to develop and support open data access, both for heavy–ion physics research and for other sub–fields, would be beneficial.

d. Community Driven Repositories of Knowledge (K. Godbey) The Advanced Scientific Computing and Statistics Network (ASCSN) [49] fosters collaborations and builds connections between developers in computational science, machine learning, statistics, and applied mathematics, and in application domains which benefit from such developments. The ASCSN scope also includes Cloud Computing and Machine Learning.

The ASCSN community-driven forum has been used to support FRIB summer schools [50]. Pedagogical resources of this kind lower the entry barrier for scientists across a wide spectrum of institutions, backgrounds, and career stages. However, there is currently no established funding framework for the sustained support of such efforts. This arises in significant part because their scientific focus is cross-disciplinary, at the boundaries of nuclear physics, computer science, and data science, and therefore not clearly within the purview of any one funding agency. New funding approaches to address such cross-disciplinary pedagogical efforts would be beneficial.

## V. OBSERVATIONS

The NP advanced computing landscape, as sketched in Sect. IV, is wide-ranging, encompassing large teams addressing broadly-defined themes in theory, experiment, and their intersection, and small teams focusing on more limited, targeted questions. NP projects are carried out at leading accelerator facilities, at high-performance computing facilities, and on small, purpose-built computing systems and experimental equipment. The current community needs and requirements for the support and development of advanced computing are consequently highly diverse, with no single set of proposed solutions applicable to the entire community.

In order to address this diversity of applications and requirements, detailed discussion at the workshop was carried out in three parallel Working Groups, focusing on theory, on experiment, and on joint theory/experimental collaborations. Each Working Group reported the results of their deliberations in a follow-up plenary session, and in written documentation. This section summarizes the observations made in those discussions on the issues affecting advanced computing efforts in NP, including research group practices, facility configuration, and funding instruments. Despite the differing scientific scope being addressed by the three Working Groups, many observations and proposed solutions were found to be common among them. This section therefore presents these observations in a unified way.

## A. Computing scope and requirements across NP

Nuclear Physics experiments vary widely in scale, from large collaborations at major facilities to small university-based programs. NP theory efforts likewise vary widely in scale, from large collaborations focusing on lattice QCD, modeling of the Quark-Gluon Plasma, or neutron star dynamics, to few-author calculations. Joint collaborations of theorists, experimentalists, and computing and data scientists are typically on the larger side.

The size and scope of a collaboration are correlated with its capabilities for software development and maintenance. Large labs have access to significant software engineering effort and resources, to build robust software infrastructure. In contrast, smaller collaborations that do not have direct access to Lab resources may not be able to develop and maintain adequate software solutions themselves, due to limited access to expertise and funding. Ensuring such support is crucial to ensure that small experiments can achieve their scientific objectives.

The data generated by various projects also differ in size and complexity, with large projects producing vast amounts of data that require sophisticated data management and analysis pipelines, and therefore a flexible and scalable approach to software development. This is an opportunity for knowledge-sharing and collaboration among experiments, both large and small. The establishment of common practices and frameworks can enhance software development across the board, and foster a culture of collaboration.

Reproducibility and replicability are crucial aspects of the scientific process, ensuring that research findings are reliable and can be independently verified. Nuclear physics research, both experimental and theoretical, often involves complex, multi-step workflows, with many stages of data manipulation and analysis. Such complexity can make it challenging to track the origin and evolution of data and code, obscuring the path taken from raw data to final results. Open-source analysis code and workflows can help in this regard. However, analysis procedures often incorporate undocumented assumptions or rely on internal knowledge - information that is passed down within a research group but not formally recorded - potentially resulting in misinterpretation or difficulty in replicating or reinterpreting the work.

The absence of such expert knowledge, if not explicitly documented, is a significant barrier to transparency and reproducibility. Good practices to address these challenges include version control systems for code, cataloged documentation of analysis procedures, and the development of standardized data formats and analysis pipelines. Containerization technologies such as Docker can also help to encapsulate software dependencies and ensure reproducibility across different computing environments.

## B. Software development

As noted in Sect. IV B, NP research includes many theory, experimental, and joint theory/experimental collaborative efforts, with a broad range in scope and size. Some collaborations are funded specifically to develop software as a service to the community, while others are primarily science–driven, with the software a by–product to some degree. In both cases, the collaborative approach is beneficial, enabling sustained discussion, organized distribution of tasks, and sharing of knowledge. Computing-oriented nuclear physicists and research software engineers are crucial elements of such multi-disciplinary projects, both for developing software infrastructure and for training physics students and postdocs.

Software development and operations in large projects should not be regarded as separate efforts. By fostering collaboration between these teams, experiments can benefit from continuous improvements and immediate feedback, promoting software robustness and functionality.

The application of AI/ML can significantly improve software efficiency, reproducibility, and interpretability. Physics-driven algorithms enhance both data analysis and decisionmaking processes. The integration of innovative tools from outside the traditional community likewise may enhance software capabilities. However, the awareness of deprecated software is necessary to prevent reliance on outdated systems.

## C. Common tools

Multi-disciplinary collaborations can achieve innovative solutions by reusing existing tools and adapting them for nuclear physics applications. Common software tools should be modular and portable, using common standards and with meaningful documentation.

During the workshop, several common techniques were identified among NP projects, including Bayesian inference and other inverse-problem solutions, Machine Learning applications, adaptive grids, and numerical linear algebra. Common issues include uncertainty quantification, data storage and sharing, and software development and stewardship beyond the funding period. Common tools include Kokkos, Docker, and QUDA.

## D. Resource access

Advanced computing projects commonly require long-term HPC resource allocation, using mechanisms such as ERCAP/NERSC, INCITE/ASCR, Jetstream2/Indiana, Access/NSF, and ALCC/ASCR. Optimally, funding for project effort should be accompanied by an HPC allocation, which then does not need to be applied for separately. SciDAC has followed this approach, which has been effective in advancing large-scale projects.

For software to be utilized effectively, it must be easily discoverable. Creating a comprehensive catalog of available software used within the NP community would facilitate access and enhance user engagement.

Strengthening partnerships between academic institutions and larger laboratories can help small experimental programs gain access to vital software engineering talent and resources.

### E. Workforce

Nuclear Physics is increasingly dependent upon high-performance computing and largescale data analysis to address forefront research problems. NP researchers must develop skills and expertise in advanced computing, which creates a workforce that has capabilities in technical areas of computing and data science which have much wider applicability. Professional research software engineers and computational scientists are crucial partners in NP scientific projects requiring advanced computing. Currently, it is challenging for early-career nuclear physicists who wish to pursue an academic position to focus on software development, since hiring metrics for faculty positions are based primarily on publications, citations, and presentations at conferences, while software development is not recognized at the same level. The workshop consensus was to advocate for the support of long-term positions for nuclear physicists, both theorists and experimentalists, with the skills and interest in the development and stewardship of software.

The establishment of robust career paths and support for scientific software developers within NP is crucial for retaining talent within the field. This includes mentorship programs, training opportunities, and recognition of software contributions as integral to scientific research.

The field should explore ways to acknowledge software and computing as essential components of projects and experiments, and to ensure that they receive adequate funding. This could include emphasis in project proposals on analysis methodology and computing resource requirements. Such efforts would provide a clear career path, and establish a stable workforce for long-term software stewardship.

It is similarly important to train the next generation of computing-focused scientists, fostering students who show interest and aptitude in this area. A strong foundation in data science includes expertise in data manipulation, analysis, and visualization techniques, as well as machine learning and uncertainty quantification. Likewise important is the cultivation of cross-disciplinary communication and collaboration skills. These skills are also valued in the broader workforce, enabling successful careers outside of academia.

An organization focused on software development and stewardship in NP could develop and disseminate training modules and video tutorials, and run online training and discussion sessions, and hackathons. The community should leverage currently existing and supported training programs (e.g. DOE-funded undergraduate traineeships) and community resources, and develop new programs as appropriate. Institutional and collaboration mentorship programs also have a valuable role in this area.

The current demographic profile of the NP research community does not reflect that of society as a whole. Outreach to under-represented communities is a vital, ongoing aspect of training of the next generation.

It is also important to recognize that expertise outside Nuclear Physics is valuable to the NP enterprise. This requires avenues to promote multi-disciplinary opportunities, with the possibility of recruiting the needed expertise when it is not within the conventional NP boundaries. Partnerships with industry are also beneficial to the NP research program and to the training of students and postdocs, while opening up future employment opportunities for them.

#### F. Connection to Industry

To maximize the value of Nuclear Physics, partnerships with vendors are crucial. For classical computing, close collaboration with large companies such as Nvidia, Intel, and IBM provides efficient use of state-of-the-art GPU-accelerated machines, among other things. For Quantum Computing, ongoing projects with companies such as IBM, Microsoft, IonQ, and Quera are crucial for the development of NP quantum computing.

The Small Business Innovation Research (SBIR) program provides essential funding for modest-scale R&D, enabling researchers to explore forefront technologies and practices that could benefit multiple laboratories.

## G. Software stewardship

Software stewardship requires significant effort. Funding support would be beneficial for adapting existing HPC codes to run on new platforms and for the integration of new elements into existing software. The effort for data preservation and re-analysis likewise requires support.

Institutional computing centers play an important role in the development and stewardship of common software ecosystems, and should ensure that the barrier to entry is low and that software information and support are readily available.

Many applications of of AI/ML to NP are being developed and will need support for stewardship. In the case of Quantum Information Science, companies have significantly more resources for supporting these efforts than universities and national laboratories. However, such resources are volatile, and US funding agencies have a role in supporting their preservation beyond the lifetime of company investments.

Similarly, sustained support is needed for open-source software, especially frameworks developed by large collaborations, beyond their nominal period of operations.

#### H. Data and analysis preservation

The curation and preservation of data and analysis are essential to ensure the longevity and reproducibility of scientific research. As the complexity of scientific workflows grows, the re-analysis of data and reproducibility of results have become significant challenges. During the active phase of many projects, the focus is primarily on immediate physics results, rather than on long-term archival needs. Following completion of the active project phase, analysis and simulation tools tend to become black boxes, with insufficient documentation and complicated dependencies, making reliable data re-analysis difficult or impossible. To address this challenge it is necessary to preserve both raw data and its associated software, workflows, calibration metadata, and ML models. The infrastructure to support this task must allow both for long-term storage and for future usability of these resources.

There is an additional, less tangible but no less important, element to data preservation, which is the preservation of institutional knowledge. There have been recent efforts to re-analyze archived data from the LEP  $e^+e^-$  collider at CERN [51–53], which terminated operation in 2000, and the HERA e+p Collider at DESY [54–59], which terminated operation in 2008. In addition, the currently-running CMS Collaboration at the LHC has released open data from early LHC runs, which has been analyzed by external groups [60, 61]. The collider detectors involved, and datasets and analysis correction schemes, are too complex to fully document all necessary details in a comprehensible way; practical experience with these re–analyses has revealed that bringing them to publication-level quality required expert knowledge from physicists who participated in the experimental operations and analysis during the active phase of the project. This is an important in-practice lesson for data curation and preservation projects: expert knowledge also needs to be preserved. The absence of well-defined career paths for scientists focused on the development and maintenance of domain-specific software therefore presents a significant challenge for data preservation.

The workshop discussion identified the following specific challenges for data and analysis preservation:

- Infrastructure Needs: Long-term infrastructure is necessary to store data, software, and metadata, ensuring that archived workflows can still be executed in the future.
- **Standardization:** The lack of standardized and well-documented formats for storing data and workflows presents a barrier to reproducibility and collaboration.

- **Discoverability:** Even if data and workflows are preserved, ensuring they are easily discoverable by future researchers needs additional attention.
- **Centralized Support:** Some tasks, such as maintaining archiving infrastructure and creating best-practice policy documents, may require centralized efforts and community-wide coordination.
- Software Lifecycle Planning: Ensuring the sustainability of software through lifecycle management and planning, including provisions for future updates and adaptability to new platforms, is crucial.
- Proprietary Software/Hardware R&D efforts within non-NP organizations and industry play a critical role in cutting–edge endeavors such as AI/ML and Quantum computing. Such external organizations often provide extensive resources to the NP community to support these activities. It is important to ensure that such resources (proprietary tool chains, compilers, libraries, cloud services) do not disappear or are withdrawn, which could render large datasets unrecoverable or uninterpretable.
- Decentralized storage networks: Investment should be considered in decentralized storage networks, leveraging and extending mature technologies such as IPFS [62], to flexibly distribute responsibility and to lower the cost of long-term storage of scientific data products.
- Software Stewardship: Adequate resources for software stewardship are required to ensure that existing software can adapt to new platforms and technological advances, such as AI/ML and quantum computing.

## VI. OPPORTUNITIES

In this section, we summarize the opportunities arising from the Observations presented in Sect V, which can transform NP research through the adoption of new technologies and a targeted and expanded expert workforce.

## A. Community organization

A strong consensus of the workshop participants is the need for a standing committee representing the broad NP community, to coordinate discussion and provide guidance on matters related to advanced NP computing. This committee could also be charged with organizing periodic meetings on advanced NP computing, similar in nature to this workshop. As noted in Sect. IV, the NP computational community comprises a wide range of organized collaborations and smaller, less formal efforts, with diverse needs for support. The scope of discussions at such meetings could include software stewardship, workforce development, cross-project support and coordination, and data curation and preservation.

#### B. Innovation

Sustainable software infrastructure for NP discovery requires innovation in hardware and algorithmic developments, and the inclusion of approaches and best practices from industry. Such innovations are often implemented in common software ecosystems that have broad applications in the NP research portfolio. The importance of these ecosystems is expected to increase as they incorporate further innovations. We echo the recommendations of the 2023 NSAC Long Range Plan to support a multi-institution Quantum Computing Center, and a coordinated effort to incorporate AI/ML techniques into NP.

New technical developments provide additional opportunities for scientific discovery; such developments include advanced nuclear theory algorithms, and applications of AI/ML and Quantum Computing. Accelerated computing at mixed and reduced precision is likewise a promising approach for software solutions in several areas.

#### C. Crosscutting Initiatives

The NP research enterprise has benefited greatly from multi-disciplinary efforts, such as SciDAC-supported projects, which combine innovations in computational science, applied mathematics, statistics, and emerging industries. This multi-disciplinary approach is essential for the NP program to exploit the the rapid and accelerating development of AI/ML technologies. Such multi-disciplinary, technically challenging projects are likewise attractive to experts in scientific and technical domains beyond NP, fostering partnerships between fields and between academia and industry which are beneficial for workforce development.

Large-scale collaborative efforts and smaller, more targeted projects serve complementary roles in the NP software ecosystem and flexibility in support mechanisms is important, to enable projects of widely varying scale and levels of maturity.

#### D. Stewardship

Within the NP community there is a large body of community software and infrastructure, representing a significant investment over many years. Such software and infrastructure developed for scientific research are increasingly viewed as valuable assets which need to be preserved. As an example, following the completion of the Exascale Computing Project, DOE ASCR is providing direct support of software stewardship for codes and libraries that it considers to be essential for its scientific efforts and facilities.

Stewardship provides users with the assurance of continued availability, reducing duplication of effort and code bases, and standardizes software citations as recognition and an incentive for code authors. Stewardship enables the evolution of applications, providing a development path for functionality on new HPC and other systems as they emerge.

Stewardship of existing software therefore complements the development of new capabilities in software and computing. Maintenance of this investment, by active stewardship and management of its life cycle, is an important target of funding support.

## E. Data Curation and Preservation

The development of robust mechanisms for preservation of data and associated metadata, including research software and workflows, will ensure their long-term accessibility and the reproducibility of scientific results, thereby maximizing the return on investment in current and future nuclear physics facilities and instruments.

Mechanisms for the curation and preservation of data were found to be common to experimental and theoretical efforts in NP. As experimental and computational abilities have advanced, the consideration of policies governing data stewardship has become more complex. The stewardship and preservation of AI/ML methods in analysis workflows is especially challenging, given their dependence on training data and model construction.

## F. Workforce development

Nuclear Physics is increasingly dependent on high performance computing and large scale data analysis to address forefront research problems. Data physicists provide specialized skills in data management and curation, algorithm development, and software engineering. This dependency places a premium on career paths for scientific software developers, to drive innovation through the adoption of new technologies such as AI/ML, and to support operations.

The support of viable career paths and incentive structures for scientific software developers at the intersection of nuclear physics, data science, and computing is critical for retaining and developing talent within the field of Nuclear Physics. Retention mechanisms for such staff include mentorship programs, training opportunities, and recognition of software contributions as integral to scientific research.

## Appendix A: Workshop organization and agenda

## 1. Workshop organizing committee

- Amber Boehnlein (JLab), co-chair
- Peter Jacobs (LBNL), co-chair
- Joe Carlson (LANL)
- Ian Cloet (ANL)
- Markus Diefenthaler (JLab)
- Robert Edwards (JLab)
- Raphael Hix (ORNL)
- Thomas Papenbrock (UTK)
- Brad Sawatzky (JLab)
- Torre Wenaus (BNL)

## 2. Workshop agenda

Workshop indico page: [3].

Agenda:

Plenary: Thursday, June 20			
Time	Title		Presenter
09:00	Welcome		SAWATZKY, Brad
09:05	Introduction to SANPC		BOEHNLEIN, Amber
09:20	MUSES		MANNING, T. Andrew
09:40	ENAF		HIX, W Raphael
10:00	NUCLEI		PAPENBROCK, Thomas
10:20		Break	
10:50	BAND		GODBEY, Kyle
11:10	JETSCAPE		MAJUMDER, Abhijit
11:30	QuantOm		CLOET, Ian
11:50	SciDAC FastMath		MUNSON, Todd

12:10	Infrastructure for Nuclear Nonproliferation Data Science	ADAMSON, Paul
	Research	
12:30	Lunch	
13:30	Exp - Collider (RHIC, LHC, EIC)	PLOSKON, Mateusz
13:55	Exp - JLab/FRIB	LIDDICK, Sean
14:20	Computing for Neutrino Physics	BRODSKY, Jason
14:55	Break	
15:25	JLab Angular Momentum (JAM)	MELNITCHOUK, Wally
15:45	LQCD	DETMOLD, William
16:15	iQUS	SAVAGE, Martin
16:35	Community-driven repositories of knowledge	GODBEY, Kyle
16:45	Sharing simulation data with community	SHEN, Chun
16:55	Maintaining and Refactoring Legacy Code	FLORES, Abraham
17:05	Challenges in non-equilibrium many-body dynamics	BULGAC, Aurel
17:15	HPC and Quantum Computing in Nuclear Dynamics	CARLSON, Joseph
17:25	QMC calculations of nuclear responses: beyond Carbon	ANDREOLI, Lorenzo
17:35	ML for [high-energy] Nuclear Physics	PLOSKON, Mateusz
17:45	Neural Network for low-energy nuclear structure	GNECH, Alex
17:55	Optimization with Correlated Errors	SOLTZ, Ron
18:05	TListSpectrum: toolset for spectroscopic analysis	GARLAND, Heather
18:15	Future proofing your research	BROWN, David

<b>Plenary:</b>	Friday,	June	<b>21</b>
-----------------	---------	------	-----------

Time	Title	Presenter
08:30	Software Stewardship at ASCR	DUBEY, Anshu
08:50	Composable Optimization and Control Toolkit for	RAJPUT, Kishansingh
	Scientific Applications	
09:10	Data Science: Unique NP Challenges	NACHMAN, Ben
09:30	Panel Discussion with Agencies	

Time	Title	Organizers
10:50	Session 1: Experiment	DIEFENTHALER, Markus and
		PLOSKON, Mateusz
10:50	Session 2: Theory	RATTI, Claudia and
		ORGINOS, Kostas
13:30	Session 1: Experiment	DIEFENTHALER, Markus and
		PLOSKON, Mateusz
13:30	Session 2: Theory	RATTI, Claudia and
		ORGINOS, Kostas
13:30	Session 3: Joint Theory and Experiment	GODBEY, Kyle and
		SOLTZ, Ron

## Parallel Sessions: Friday, June 21

	Plenary: Saturday, June 22
Time	Title
09:00	White Paper open discussion
