Defense Strategies for Autonomous Multi-agent Systems: Ensuring Safety and Resilience Under Exponentially Unbounded FDI Attacks

Yichao Wang, Mohamadamin Rajabinezhad, Rui Liu, and Shan Zuo

Abstract—False data injection (FDI) attacks pose a significant threat to autonomous multi-agent systems (MASs). While resilient control strategies address FDI attacks, they typically have strict assumptions on the attack signals and overlook safety constraints, such as collision avoidance. In practical applications, leader agents equipped with advanced sensors or weaponry span a safe region to guide heterogeneous follower agents, ensuring coordinated operations while addressing collision avoidance to prevent financial losses and mission failures. This letter addresses these gaps by introducing and studying the safety-aware and attack-resilient (SAAR) control problem under exponentially unbounded FDI (EU-FDI) attacks. Specifically, a novel attackresilient observer layer (OL) is first designed to defend against EU-FDI attacks on the OL. Then, by solving an optimization problem using the quadratic programming (QP), the safety constraints for collision avoidance are further integrated into the SAAR controller design to prevent collisions among followers. An attack-resilient compensational signal is finally designed to mitigate the adverse effects caused by the EU-FDI attack on control input layer (CIL). Rigorous Lyapunov-based stability analysis certifies the SAAR controller's effectiveness in ensuring both safety and resilience. This study also pioneers a threedimensional simulation of the SAAR containment control problem for autonomous MASs, demonstrating its applicability in realistic multi-agent scenarios.

Index Terms—Containment, resilience, unbounded attacks, safety constraints.

I. INTRODUCTION

Containment control in autonomous multi-agent systems (MASs) has become essential in real-world applications, particularly involving unmanned aerial vehicles (UAVs) [1] and unmanned ground vehicles (UGVs) [2]. This control strategy enables leader agents, often equipped with advanced sensors or weaponry, to guide follower agents within a designated safe region, ensuring coordinated movement and operational safety. Such scenarios are common in tasks such as surveillance, reconnaissance, and military operations, where maintaining cohesion and mitigating risks are critical. The heterogeneity of agents, characterized by differing models, structures, or capabilities, adds complexity to the problem, necessitating advanced control algorithms. Moreover, collision avoidance plays a pivotal role in containment control, as collisions can lead to substantial financial losses and mission failures, highlighting the importance of integrating safety measures into control strategies.

In the MAS framework, false data injection (FDI) attacks pose significant threats to autonomous MASs and impact critical infrastructures and mission-essential cyber-physical systems, such as power systems, transportation networks, and combat-zone multi-robot systems [3]. To mitigate the impact of FDI attacks, two primary approaches have been proposed. The first one involves detection and identification of compromised agents, followed by their removal [4], [5]. However, this method relies on additional assumptions, such as limiting the number of compromised agents. These assumptions are often impractical, attackers typically aim to compromise all agents and communication channels whenever feasible. To address these limitations, a second approach has been developed, focusing on the design of attack-resilient control protocols [6]-[10]. Rather than removing compromised agents, this strategy aims to minimize the adverse effects of attacks through resilient control mechanisms. However, the aforementioned research neglects safety constraints, such as collision avoidance, leading to potential collision risks. On the other hand, methods incorporating safety constraints often solve optimization problems for control input but typically lack resilience to FDI attacks [11]-[15]. Additionally, most studies addressing FDI resilience assume the observer laver remains intact and either disregard attacks or handle only bounded attack signals with bounded first-time derivatives, which are impractical assumptions [6], [16]. Adversaries can exploit these limitations using rapidly growing signals, such as exponentially unbounded FDI (EU-FDI) attacks, to compromise the system.

In real-world scenarios, ensuring both safety and resilience to EU-FDI attacks is critical for the reliable operation of safety-critical MASs. Recognizing this need, the safe and attack-resilient (SAAR) control problem is studied in this work. The primary challenge lies in designing a controller that is resilient to EU-FDI attacks while consistently enforcing safety constraints, specifically collision avoidance. The contributions are as follows.

• A novel attack-resilient OL is first designed to defend against EU-FDI attacks on the OL. Then, by solving an optimization problem using the QP, the safety constraints for collision avoidance are further integrated into the SAAR controller design to prevent collisions among followers. An attack-resilient compensational signal is finally designed to mitigate the adverse effects caused by the EU-FDI attack on CIL. To the best of the authors' knowledge, this letter is the first to address EU-FDI attacks on both OL and CIL. Moreover, this letter is the first to investigate both attackresilience and collision avoidance among followers. • Rigorous mathematical proof using Lyapunov-based stability analysis is provided to certify the effectiveness of the proposed SAAR controller in guaranteeing both safety constraints and attack resilience under EU-FDI attacks on both OL and CIL.

• This work is the first to simulate a three-dimensional space to investigate the SAAR control strategies, extending the dimensional scope beyond previous two-dimensional space, which reflects a more realistic application for the containment control problem.

This paper is structured as follows: Section II provides the preliminaries and problem formulation. Section III describes the safe and resilient controller design, including the design of the observer, the control strategies, the safety constraints, the main result and we provide the stability analysis and prove that the proposed control guarantees the containment and safety of the autonomous MAS. Finally, Section IV presents the simulation results, and Section V concludes the paper.

II. PRELIMINARIES AND PROBLEM FORMULATION

||x|| denotes the Euclidean norm of a vector $x \in \mathbb{R}^n$. The symbol ∂S represents the boundary of a closed set S. $L_f V(x) = \frac{\partial V}{\partial x} f(x)$ is the Lie derivative of a function $V: \mathbb{R}^n \to \mathbb{R}$ along a vector field $f: \mathbb{R}^n \to \mathbb{R}^n$. $I_N \in \mathbb{R}^{N \times N}$ is the identity matrix. $\mathbf{1}_N, \mathbf{0}_N \in \mathbb{R}^N$ are the column vectors with all elements of zero and one, respectively. The Kronecker product is represented by \otimes . The operator diag(\cdot) forms a block diagonal matrix from its argument. The notations $\sigma_{\min}(X)$ and $\sigma_{\max}(X)$ represent the minimum singular value and the maximum singular value respectively. \Box denotes corrupted signal. Consider a system of N+M agents in a digraph \mathcal{G} , composed of N followers and M leaders. Let the sets of followers and leaders be denoted by $\mathscr{F} = \{v_1, v_2, \dots, v_N\}$ and $\mathscr{L} = \{v_{N+1}, v_{N+2}, \dots, v_{N+M}\}$, respectively. \mathcal{N}_i represents the set of neighboring followers of follower i within the follower set. The interactions between followers are described by the subgraph $\mathscr{G}_f = (\mathcal{V}, \mathcal{E}, \mathcal{A})$, where \mathcal{V} is the set of nodes, $\mathcal{E} \subset \mathcal{V} \times \mathcal{V}$ is the set of edges, and $\mathcal{A} = [a_{ij}] \in \mathbb{R}^{N imes N}$ is the adjacency matrix. Here, a_{ij} represents the weight of edge (v_j, v_i) , with $a_{ij} \neq 0$ if $(v_j, v_i) \in \mathcal{E}$, and $a_{ij} = 0$ otherwise. There are no repeated edges or self-loops, i.e., $a_{ii} = 0$ for all i. A directed path from node i to node j is defined as a sequence of edges $\{(v_i, v_k), (v_k, v_l), \dots, (v_m, v_j)\}$. The matrix $\mathcal{G}_r = \operatorname{diag}(g_{ir}) \in \mathbb{R}^{N \times N}$, where $i \in \mathscr{F}$ and $r \in \mathscr{L}$, represents the diagonal matrix of pinning gains from the r-th leader to each follower. Specifically, $g_{ir} \neq 0$ if a connection from the *r*-th leader to the *i*-th follower exists; otherwise, $g_{ir} = 0$. The digraph \mathscr{G} is assumed to be time-invariant, meaning that both \mathcal{A} and \mathcal{G}_r are constant. $\mathcal{D} = \operatorname{diag}(d_i) \in$ $\mathbb{R}^{N \times N}$ with $d_i = \sum_{j \in \mathcal{N}_i} a_{ij} > 0$. $\mathcal{L} = \mathcal{D} - \mathcal{A}$. Denote $\Phi_r = \frac{1}{M} \mathcal{L} + \mathcal{G}_r$. The states of the leaders are represented by the set $X_{\mathscr{L}} = \{x_{N+1}, x_{N+2}, \dots, x_{N+M}\}.$

We consider a group of N heterogeneous agents (followers) described by the following linear dynamics:

$$\dot{x}_i(t) = A_i x_i(t) + B_i \bar{u}_i(t), \quad i \in \mathscr{F}, \tag{1}$$

where $x_i(t) \in \mathbb{R}^n$ is the state, $\bar{u}_i(t) \in \mathbb{R}^{m_i}$ is the corrupted control input. The matrices $A_i \in \mathbb{R}^{n \times n}$ and $B_i \in \mathbb{R}^{n \times m_i}$ represent the system dynamics and input matrices, respectively. The corrupted input \bar{u}_i of the i^{th} follower is

$$\bar{u}_i(t) = u_i(t) + \gamma_i^a(t), \qquad (2)$$

where $u_i(t) \in \mathbb{R}^{m_i}$ is the intact control input and $\gamma_i^a(t) \in \mathbb{R}^{m_i}$ is of class C^1 [17] that represents the EU-FDI attack signal injected to the i^{th} follower. The M leaders with the following dynamics can be viewed as command generators that generate the desired trajectories:

$$\dot{x}_r(t) = S x_r(t), \quad r \in \mathscr{L},\tag{3}$$

where $x_r(t) \in \mathbb{R}^n$ is the state of the *r*th leader. The matrices A_i and B_i may vary across different agents, making the system heterogeneous.

Definition 1 ([18]). The convex hull $Co(X_{\mathscr{L}})$ is the minimal convex set containing all points in $X_{\mathscr{L}}$, defined as:

$$Co(X_{\mathscr{L}}) = \left\{ \sum_{r \in \mathscr{L}} a_r x_r \mid a_r \ge 0, \sum_{r \in \mathscr{L}} a_r = 1 \right\},$$

where $\sum_{r \in \mathscr{L}} a_r x_r$ represents certain convex combination of all points in $X_{\mathscr{L}}$.

Definition 2 ([19]). The signal $x(t) \in \mathbb{R}^n$ is said to be UUB with the ultimate bound b, if there exist positive constants b and c, independent of $t_0 \ge 0$, and for every $a \in (0, c)$, $\exists T = T(a, b) \ge 0$, independent of t_0 , such that

$$\|x(t_0)\| \leqslant a \quad \Rightarrow \quad \|x(t)\| \leqslant b, \forall t \ge t_0 + T \tag{4}$$

Assumption 1. *Each follower in the digraph G*, *has a directed path from at least one leader.*

Assumption 2. S has non-repeated eigenvalues on the imaginary axis.

Assumption 3. The pair (A_i, B_i) is controllable for each follower.

Given Assumption 3, the following linear matrix equation has a solution Π_i for each follower:

$$S = A_i + B_i \Pi_i. \tag{5}$$

Assumption 4. The attack signals $\gamma_i^a(t)$ and $\gamma_i^{ol}(t)$ (in (10)) are exponentially unbounded. That is, their norms grow at most exponentially with time. For the purposes of stability analysis, it is reasonable to assume that there exist positive constants κ_i^a and κ_i^{ol} , such that $\|\gamma_i^a(t)\| \leq \exp(\kappa_i^a t)$ and $\|\gamma_i^{ol}(t)\| \leq \exp(\kappa_i^{ol} t)$, where κ^a and κ^{ol} could be unknown.

Remark 1. Assumption 4 covers a broad range of FDI attack signals, including those that grow exponentially over time. Specifically, $\exp(\kappa_i^a t)$ and $\exp(\kappa_i^{ol} t)$ represent the worst-case scenarios the controller can handle. As long as the growth rate of the attack signals remains below these thresholds, the controller can effectively mitigate them. In practice, adversaries can inject any time-varying signal into systems through platforms such as software, CPUs, or DSPs. However, much of the existing research focuses on disturbances, noise, or bounded attack signals, or assumes that the first time derivatives of the attacks are bounded [6]. Let $\bar{x}_r = \mathbf{1}_N \otimes x_r$. Define the global containment error as

$$e_{c} = x - \left(\sum_{\nu \in \mathscr{L}} (\Phi_{\nu} \otimes I_{n})\right)^{\top} \sum_{r \in \mathscr{L}} (\Phi_{r} \otimes I_{n}) \bar{x}_{r}, \quad (6)$$

where $x = [x_{1}^{\top}, ..., x_{N}^{\top}]^{\top}.$

Lemma 1 ([20]). Given Assumption 1, the containment control objective is achieved if $\lim_{t\to\infty} e_c(t) = 0$. That is, each follower converges to the convex hull spanned by the leaders.

We need the following definition to introduce the concept of a *safe set*.

Definition 3. A set $S \subset \mathbb{R}^n$ is forward invariant with respect to a control system if, for all initial conditions $x(0) \in S$, the system's trajectory satisfies $x(t) \in S$ for all $t \ge 0$.

The forward invariance of the safe set is guaranteed using control barrier functions (CBFs). A CBF ensures that the system remains within the safe set by satisfying certain conditions, as described in Definition 4 as follows.

Definition 4 ([21]). Let α be a monotonically increasing, locally Lipschitz class \mathcal{K} function with $\alpha(0) = 0$, given a set $S \subset \mathbb{R}^n$ as defined in Definition 3, a function h(x) is CBF candiate, if the following condition is satisfied:

$$\inf_{u \in \mathcal{U}} \left[L_f h(x) + L_g h(x) u \right] \leqslant -\alpha(h(x)), \tag{7}$$

where \mathcal{U} is the set of admissible control inputs.

In (7), $L_f h(x)$ and $L_g h(x)$ denote the Lie derivatives of the function h(x) along the vector fields f and g, respectively. For a general system of the form:

$$\dot{x} = f(x) + g(x)u,$$

the terms $L_f h(x) = \frac{\partial h}{\partial x} f(x)$ and $L_g h(x) = \frac{\partial h}{\partial x} g(x)$ involve the gradients of h(x) with respect to the state x.

Now, consider our specific case where h(x) applied locally corresponds to $h_{S_{ij}}(x_i, x_j)$. We apply aforementioned general concepts to our specific case, where the safe set for collision avoidance is defined as:

$$S_{S_{ij}} \triangleq \{ x_i \in \mathbb{R}^n \mid h_{S_{ij}}(x_i, x_j) \leqslant 0 \},\$$

with the specific CBF:

$$h_{S_{ij}}(x_i, x_j) \triangleq d_s^2 - ||x_i - x_j||^2$$

where d_s is the minimum allowable safe distance. The system dynamics are given by:

$$\dot{x}_i(t) = A_i x_i(t) + B_i u_i(t), \quad \forall i \in \mathscr{F}.$$

In this case, the vector field f(x), applied to linear time invariant system locally, corresponds to $A_i x_i$, and g(x)ucorresponds to $B_i u_i$. To avoid confusion, we denote the Lie derivatives as $L_f h_{S_{ij}}$ and $L_g h_{S_{ij}}$, where f and g are defined as above.

Lemma 2. Given the set $S_{S_{ij}}$ and the CBF $h_{S_{ij}}(x_i, x_j)$, if the control input u_i satisfies:

$$\inf_{u_i \in \mathcal{U}_i} \left[L_f h_{S_{ij}} + L_g h_{S_{ij}} u_i \right] \leqslant -\alpha (h_{S_{ij}}) - 2(x_i - x_j)^\top \dot{x}_j,$$
(8)

then the system ensures that $||x_i - x_j|| \ge d_s$ for all $t \ge 0$.

Proof: By definition, the specific CBF is given as:

$$a_{S_{ij}}(x_i, x_j) = d_s^2 - ||x_i - x_j||^2.$$

Taking the time derivative of $h_{S_{ij}}(x_i, x_j)$ along the system dynamics, we have:

$$\dot{h}_{S_{ij}}(x_i, x_j) = -\frac{d}{dt} ||x_i - x_j||^2.$$

Expanding $||x_i - x_j||^2 = (x_i - x_j)^\top (x_i - x_j)$, its time derivative is:

$$\frac{d}{dt} \|x_i - x_j\|^2 = 2(x_i - x_j)^\top (\dot{x}_i - \dot{x}_j).$$

Substituting this into $h_{S_{ij}}(x_i, x_j)$, we obtain:

$$n_{S_{ij}}(x_i, x_j) = -2(x_i - x_j)^{\top} (\dot{x}_i - \dot{x}_j)$$

From the system dynamics, we know:

ł

 $\dot{x}_i = A_i x_i + B_i u_i, \quad \dot{x}_j = A_j x_j + B_j u_j.$

Substituting \dot{x}_i and \dot{x}_j into the expression for $\dot{h}_{S_{i_j}}(x_i, x_j)$, we get: $\dot{h}_{S_{i_j}}(x_i, x_j) = -2(x_i - x_j)^\top [(A_i x_i + B_i u_i) - (A_j x_j + B_j u_j)]$.

Rearranging terms, we separate the contributions of x_i , x_j , and u_i :

$$\dot{h}_{S_{ij}}(x_i, x_j) = -2(x_i - x_j)^\top A_i x_i + 2(x_i - x_j)^\top A_j x_j$$

$$-2(x_i - x_j)^\top B_i u_i + 2(x_i - x_j)^\top B_j u_j.$$
(9)

Using the Lie derivative notation, this can be written as:

$$\begin{split} \ddot{h}_{S_{ij}}(x_i, x_j) &= L_f h_{S_{ij}} + L_g h_{S_{ij}} u_i - 2(x_i - x_j)^\top \dot{x}_j, \\ \text{where,} \ L_f h_{S_{ij}} &= -2(x_i - x_j)^\top A_i x_i, L_g h_{S_{ij}} = -2(x_i - x_j)^\top B_i. \end{split}$$

To ensure forward invariance of $S_{S_{ij}}$, we impose the condition:

$$h_{S_{S_{ij}}}(x_i, x_j) \leqslant -\alpha(h_{S_{ij}}).$$

Substituting the expanded form of $h_{S_{ij}}(x_i, x_j)$, we obtain:

$$L_f h_{S_{ij}} + L_g h_{S_{ij}} u_i \leq -\alpha(h_{S_{ij}}) - 2(x_i - x_j)^{\top} \dot{x}_j$$

This inequality ensures that the safe set $S_{S_{ij}}$ is forward invariant. Thus, if the control input u_i satisfies the optimization criterion:

$$\inf_{u_i \in \mathcal{U}_i} \left[L_f h_{S_{ij}} + L_g h_{S_{ij}} u_i \right] \leqslant -\alpha(h_{S_{ij}}) - 2(x_i - x_j)^\top \dot{x}_j,$$

then $\|x_i - x_j\| \ge d_s$ is guaranteed for all $t \ge 0$.

The following definition introduces the SAAR control problem.

Definition 5 (SAAR). For the heterogeneous autonomous MAS described in (1)-(3) under EU-FDI attacks, the SAAR control problem is to design control input $u_i \in U_i$ in (2), such that 1) the UUB containment control objective is achieved, i.e., the state of each follower converges to a small neighborhood around or within the dynamic convex hull spanned by the states of the leaders and 2) the state $x_i(t)$ remains within the safe set $S_{S_{ij}}$ for all $t \ge 0$ in the presence of EU-FDI attacks on both OL and CIL.

Remark 2. The SAAR problem addresses key challenges in practical applications of autonomous MASs. In scenarios such as surveillance, reconnaissance, and military operations, leader agents (e.g., UAVs or UGVs) equipped with advanced sensors or weaponry span a safe region to guide follower agents, ensuring coordinated and secure operations. The heterogeneity of these systems, characterized by diverse agent models and dynamics, necessitates control strategies that accommodate such differences. Moreover, collision avoidance is integral to maintaining operational safety and preventing financial and mission-critical losses. These considerations naturally align with the requirements addressed in the SAAR problem, demonstrating its relevance to real-world MASs.

III. SAFE AND RESILIENT CONTROLLER DESIGN

In this section, we propose a fully distributed, safe, and resilient containment control framework to address the SAAR control problem. First, we introduce a fully distributed, attackresilient OL to estimate the convex combinations of the leaders' states.

$$\dot{\zeta}_i = S\zeta_i + \exp(\vartheta_i)\xi_i + \gamma_i^{ol}, \tag{10}$$

$$\vartheta_i = q_i \xi_i^{\top} \xi_i, \tag{11}$$

where ζ_i is the local state on the OL (the false data injected into the bus, on which the data driving the observer dynamics is transmitted) and γ_i^{ol} represents the attack signal on the OL, ϑ_i is adaptively tuned by (11) with constant $q_i > 0$, and ξ_i represents the gathered neighborhood relative information on the OL given by

$$\xi_i = \sum_{j \in \mathscr{F}} a_{ij}(\zeta_j - \zeta_i) + \sum_{r \in \mathscr{L}} g_{ir}(x_r - \zeta_i), i \in \mathscr{F}$$
(12)

Based on this OL, we then introduce the following conventional control input design [20].

$$u_i^c = K_i x_i + H_i \zeta_i, \tag{13}$$

The matrices
$$K_i$$
 and H_i are obtained as:

$$K_i = U^{-1} B^{\top} B \qquad (14)$$

$$\mathbf{X}_{i} = -\mathbf{U}_{i} \quad \mathbf{D}_{i} \quad \mathbf{I}_{i}, \tag{14}$$

$$H_i = \Pi_i - K_i. \tag{15}$$

The matrix P_i is obtained by solving the following algebraic Riccati equation [6]:

$$A_i^{\top} P_i + P_i A_i + Q_i - P_i B_i U_i^{-1} B_i^{\top} P_i = 0.$$
 (16)

In order to guarantee the safety constraints to avoid collision, we then design the safety-aware control input u_i^s , which is computed by solving the following optimization problem:

$$\min_{u_i^s} \|u_i^s - u_i^c\|^2, \tag{17}$$

subject to the constraints:

$$\inf_{u_i \in \mathcal{U}_i} \left[L_f h_{S_{ij}} + L_g h_{S_{ij}} u_i \right] \leqslant -\delta_{ij} h_{S_{ij}} - 2(x_i - x_j)^\top \dot{x}_j,$$
(18)

where δ_{ij} is the parameters which influences the intensity of the safety constraints. We select $\alpha(h_{S_{ij}}) = \delta_{ij}h_{S_{ij}}$ [22]. Let $\Delta u_i \triangleq u_i^s - u_i^c$.

Remark 3. In [23], the scalar coupling design relies on knowledge of the global graph topology. However, as shown in (11), the adaptive coupling gain ϑ_i is designed without requiring this global topology information. Therefore, the controller is fully distributed.

Remark 4. The optimization problem formulated above ensures that the control input not only respects the safety constraints but also minimizes the deviation from the conventional control input. The solution is obtained by solving the QP problem [24]. The constraints imposed confine the

optimizer's solution u_i^s within a specific region around u_i^c , thereby rendering Δu_i bounded [11].

The SAAR control system is shown in Fig. 1. To address the attacks in (2), we finally design the following control input signal

$$u_i = u_i^s - \hat{\gamma}_i^a, \tag{19}$$

$$\hat{\gamma}_i^a = \frac{B_i^\top P_i \varepsilon_i}{\|\varepsilon_i^\top P_i B_i\| + \exp(-c_i t^2)} \exp(\hat{\rho}_i), \qquad (20)$$

$$\dot{\hat{\rho}}_i = \alpha_i \|\varepsilon_i^\top P_i B_i\|,\tag{21}$$

where the compensational signal $\hat{\gamma}_i^a$ mitigates the adverse effects caused by the attack γ_i^a (the false data injected into the communication channel, on which the data transmitted from the controller to the actuator is carried) and γ_i^{ol} , and $\hat{\rho}_i$ is adaptively tuned by (21) with constant $\alpha_i > 0$.

Fig. 1: Block diagram of the SAAR control system.

To facilitate the stability analysis, we define the followerobserver tracking error vector as

$$\varepsilon \triangleq x - \zeta,$$
 (22)

where $\zeta = [\zeta_1^{\top}, ..., \zeta_N^{\top}]^{\top}$. Define the observer containment error vector as

$$\Delta_o = \zeta - \left(\sum_{\nu \in \mathscr{L}} \left(\Phi_\nu \otimes I_n\right)\right)^{-1} \sum_{r \in \mathscr{L}} \left(\Phi_r \otimes I_n\right) \bar{x}_r, \quad (23)$$

Lemma 3 ([20]). Given Assumption 1, $\sum_{r \in \mathscr{L}} \Phi_r$ is nonsingular and positive-definite.

Theorem 1. Given Assumptions 1- 4, considering the heterogeneous autonomous MAS composed of (1)-(3) in the presence of EU-FDI attacks on both CIL and OL, the SAAR control problem is solved by designing the fully-distributed safe and resilient controller consisting of (10)-(21).

Proof: Note that the global form of (12) is

$$\xi = -\sum_{\nu \in \mathscr{L}} (\Phi_{\nu} \otimes I_N) (\zeta - \bar{x}_r)$$

= $-\sum_{\nu \in \mathscr{L}} (\Phi_{\nu} \otimes I_N) \Delta_o,$ (24)

where $\xi = [\xi_1^{\top}, ..., \xi_N^{\top}]^{\top}$. Based on Lemma 3, since $\sum_{\nu \in \mathscr{L}} (\Phi_{\nu} \otimes I_n)$ is nonsingular, to prove that Δ_o is UUB is equivalent to proving that ξ is UUB. The vector form of $\dot{\zeta}_i$ in (10) is

$$\dot{\zeta} = (I_N \otimes S)\zeta + \operatorname{diag}(\exp(\vartheta_i))\xi + \gamma^{ol}, \qquad (25)$$

where $\gamma^{ol} = [\gamma_1^{ol}^{\top}, ..., \gamma_N^{ol}^{\top}]^{\top}$. The time derivative of ξ in (24) is

$$\dot{\xi} = -\sum_{\nu \in \mathscr{L}} (\Phi_{\nu} \otimes I_{n}) (\dot{\zeta} - \dot{\bar{x}}_{r})$$

$$= -\sum_{\nu \in \mathscr{L}} (\Phi_{\nu} \otimes I_{n}) ((I_{N} \otimes S)\zeta + (\operatorname{diag}(\exp(\vartheta_{i})) \otimes I_{n})\xi)$$

$$+\gamma^{ol} - (I_{N} \otimes S)\bar{x}_{r})$$

$$= (I_{N} \otimes S)\xi - \sum_{r \in \mathscr{L}} (\Phi_{r} \otimes I_{n}) (\operatorname{diag}(\exp(\vartheta_{i})) \otimes I_{n})\xi$$

$$- \sum_{r \in \mathscr{L}} (\Phi_{r} \otimes I_{n})\gamma^{ol}.$$
(26)

We consider the following Lyapunov function candidate

$$V^{'} = \frac{1}{2} \sum_{i=1}^{N} \xi_{i}^{\top} \xi_{i} \exp(\vartheta_{i}).$$
 (27)

The time derivative of $\boldsymbol{V}^{'}$ along the trajectory of (26) is given by

$$\begin{split} \dot{V}' &= \sum_{i=1}^{N} \left(\xi_i^\top \dot{\xi}_i \exp(\vartheta_i) + \frac{1}{2} \xi_i^T \xi_i \exp(\vartheta_i) \dot{\vartheta}_i \right) \\ &= \xi^\top \operatorname{diag} \left(\exp(\vartheta_i) \otimes I_N \right) \dot{\xi} + \frac{1}{2} \xi_i^T \left(\operatorname{diag}(\exp(\vartheta_i) \dot{\vartheta}_i) \otimes I_N \right) \\ &\times \xi \end{split}$$

$$= \xi^{\top} \operatorname{diag} \left(\exp(\vartheta_{i}) \otimes I_{N} \right) \left((I_{N} \otimes S)\xi - \sum_{r \in \mathscr{L}} (\Phi_{r} \otimes I_{N}) \\ \times \left(\operatorname{diag}(\exp(\vartheta_{i})) \otimes I_{N} \right) \xi - \sum_{r \in \mathscr{L}} (\Phi_{r} \otimes I_{N}) \gamma^{ol} \right) + \frac{1}{2} \xi^{\top} \\ \times \left(\operatorname{diag}(\dot{\vartheta}_{i}) \otimes I_{N} \right) \left(\operatorname{diag}(\exp(\vartheta_{i})) \otimes I_{N} \right) \xi \\ \leqslant \sigma_{\max}(S) \| \left(\operatorname{diag}(\exp(\vartheta_{i})) \otimes I_{N} \right) \xi \| \| \xi \| - \sigma_{\min} \left(\sum_{r \in \mathscr{L}} \Phi_{r} \right) \\ \times \| \left(\operatorname{diag}(\exp(\vartheta_{i})) \otimes I_{N} \right) \xi \|^{2} + \sigma_{\max} \left(\sum_{r \in \mathscr{L}} \Phi_{r} \right) \\ \times \| \left(\operatorname{diag}(\exp(\vartheta_{i})) \otimes I_{N} \right) \xi \| \| \gamma^{ol} \| + \frac{1}{2} \max_{i} (\dot{\vartheta}_{i}) \\ \times \| \left(\operatorname{diag}(\exp(\vartheta_{i})) \otimes I_{N} \right) \xi \| \| \xi \| \\ = -\sigma_{\min} \left(\sum_{r \in \mathscr{L}} \Phi_{r} \right) \| \left(\operatorname{diag}(\exp(\vartheta_{i})) \otimes I_{N} \right) \xi \| \\ \times \left(\| \left(\operatorname{diag}(\exp(\vartheta_{i})) \otimes I_{N} \right) \xi \| - \sigma_{\max}(S) \right) \\ /\sigma_{\min} \left(\sum_{r \in \mathscr{L}} \Phi_{r} \right) \| \xi \| - \sigma_{\max} \left(\sum_{r \in \mathscr{L}} \Phi_{r} \right) \| \xi \| \\ \times \| \gamma^{ol} \| - \frac{1}{2} \max_{i} (\dot{\vartheta}_{i}) / \sigma_{\min} \left(\sum_{r \in \mathscr{L}} \Phi_{r} \right) \| \xi \| \right).$$
(28)

For convenience, denote $\phi_a = \sigma_{\max}(S)/\sigma_{\min}(\sum_{r \in \mathscr{L}} \Phi_r)$ and $\phi_b = \sigma_{\max}(\sum_{r \in \mathscr{L}} \Phi_r)/\sigma_{\min}(\sum_{r \in \mathscr{L}} \Phi_r)$, which are both positive constants. To let $\dot{V}' \leq 0$, we need

$$\| \left(\operatorname{diag}(\exp(\vartheta_i)) \otimes I_N \right) \xi \| - \phi_a \| \xi \| - \phi_b \| \gamma^{ol} \| \\ - \frac{1}{2} \max_i (\dot{\vartheta}_i) / \sigma_{\min} \left(\sum_{r \in \mathscr{L}} \Phi_r \right) \| \xi \| \ge 0.$$
⁽²⁹⁾

A sufficient condition to guarantee (29) is

$$\left(\exp(\vartheta_i) - \phi_a - \frac{1}{2} \max_i (\dot{\vartheta}_i) / \sigma_{\min} \left(\sum_{r \in \mathscr{L}} \Phi_r\right) \right) \|\xi_i\|$$

$$(30)$$

 $\geqslant \phi_b \|\gamma_i^{ol}\|.$

A sufficient condition to guarantee (30) is $\|\xi_i\| \ge \phi_b$ and $\exp(\vartheta_i) - \phi_a - 1/2 \max_i(\dot{\vartheta}_i) / \sigma_{\min}(\sum_{r \in \mathscr{L}} \Phi_r) \ge \|\gamma_i^{ol}\|$. From Assumption 4, $\|\gamma_i^{ol}(t)\| \le \exp(\kappa_i^{ol}t)$, to prove that $\exp(\vartheta_i) - \phi_a - 1/2 \max_i(\dot{\vartheta}_i) / \sigma_{\min}(\sum_{r \in \mathscr{L}} \Phi_r) \ge \|\gamma_i^{ol}\|$, we need to prove that $\exp(\vartheta_i) - \phi_a - 1/2 \max_i(\dot{\vartheta}_i) / \sigma_{\min}(\sum_{r \in \mathscr{L}} \Phi_r) \ge \exp(\kappa_i^{ol}t)$. Based on (11), when $\|\xi_i\| > \max\{\sqrt{\kappa_i^{ol}/q_i}, \phi_b\}$, which guarantees the exponential growth of $\exp(\vartheta_i)$ dominates all other terms, $\exists t_1$, such that $\forall t > t_1$, $\exp(\vartheta_i) - \phi_a - 1/2 \max_i(\dot{\vartheta}_i) / \sigma_{\min}(\sum_{r \in \mathscr{L}} \Phi_r) \ge \exp(\kappa_i^{ol}t)$. Hence, we obtain $\forall t > t_1$,

$$\dot{V}' \leqslant 0, \,\forall \|\xi_i\| > \max\{\sqrt{\kappa_i^{ol}/q_i}, \phi_b\}.$$
(31)

By LaSalle's invariance principle [25], ξ_i is UUB. Therefore, Δ_o is UUB.

Next, we prove that follower-observer tracking error ε_i is UUB. From (1), (5), (10), (19) and (15), we obtain the time derivative of the elements in (22) as $\dot{\varepsilon} = \dot{\sigma}_i$.

$$\begin{aligned} \varepsilon_i &= x_i - \zeta_i \\ &= A_i x_i + B_i K_i x_i + B_i H_i \zeta_i - B_i \hat{\gamma}_i^a \\ &+ B_i \gamma_i^a - (A_i + B_i \Pi_i) \zeta_i - \exp(\vartheta_i) \zeta_i + \Delta u_i - \gamma_i^{ol} \\ &= (A_i + B_i K_i) \varepsilon_i - B_i \hat{\gamma}_i^a - B_i \gamma_i^a - \exp(\vartheta_i) \xi_i - \gamma_i^{ol} + \Delta u_i. \end{aligned}$$
(32)

From the above proof, we confirmed ξ_i is UUB. Considering Assumption 2, (24) and (25), we obtain that $\beta_i = \exp(\vartheta_i)\xi_i - \gamma_i^{ol}$ is bounded. Let $\bar{A}_i = A_i + B_i K_i$ and $\bar{Q}_i = Q_i + K_i^{\top} U_i K_i$. Note that \bar{Q}_i is positive-definite. From (16), P_i is symmetric positive-definite. Consider the following Lyapunov function candidate

$$V_i = \varepsilon_i^T P_i \varepsilon_i, \tag{33}$$

and its time derivative is given by

$$V_{i} = 2\varepsilon_{i}^{T}P_{i}\dot{\varepsilon}_{i}$$

$$= 2\varepsilon_{i}^{T}P_{i}\left(\bar{A}_{i}\varepsilon_{i} + B_{i}\gamma_{i}^{a} - B_{i}\hat{\gamma}_{i}^{a} - \beta_{i} + \Delta u_{i}\right)$$

$$\leqslant -\sigma_{\min}\left(\bar{Q}_{i}\right)\left\|\varepsilon_{i}\right\|^{2} + 2\left(\varepsilon_{i}^{T}P_{i}B_{i}\gamma_{i}^{a} - \varepsilon_{i}^{T}P_{i}B_{i}\hat{\gamma}_{i}^{a}\right)$$

$$-2\varepsilon_{i}^{T}P_{i}\beta_{i} + 2\varepsilon_{i}^{T}P_{i}\Delta u_{i}$$

$$\leqslant -\sigma_{\min}\left(\bar{Q}_{i}\right)\left\|\varepsilon_{i}\right\|^{2} + 2\left(\varepsilon_{i}^{T}P_{i}B_{i}\gamma_{i}^{a} - \varepsilon_{i}^{T}P_{i}B_{i}\hat{\gamma}_{i}^{a}\right)$$

$$+2\sigma_{\max}\left(P_{i}\right)\left\|\varepsilon_{i}\right\|\left\|\beta_{i}\right\| + 2\sigma_{\max}\left(P_{i}\right)\left\|\varepsilon_{i}\right\|\left\|\Delta u_{i}\right\|.$$
Using (20) to obtain
$$\varepsilon_{i}^{T}P_{i}B_{i}\gamma_{i}^{a} - \varepsilon_{i}^{T}P_{i}B_{i}\hat{\gamma}_{i}^{a}$$

$$= \varepsilon_{i}^{T}P_{i}B_{i}\gamma_{i}^{a} - \frac{\left\|\varepsilon_{i}^{T}P_{i}B_{i}\right\|^{2}}{\left\|\varepsilon_{i}^{T}P_{i}B_{i}\right\|^{2}} \exp\left(\hat{\rho}_{i}\right)$$

$$\leqslant \left\|\varepsilon_{i}^{T}P_{i}B_{i}\right\|\left\|\gamma_{i}^{a}\right\| - \frac{\left\|\varepsilon_{i}^{T}P_{i}B_{i}\right\|^{2}}{\left\|\varepsilon_{i}^{T}P_{i}B_{i}\right\|^{2}} \exp\left(\hat{\rho}_{i}\right)$$

$$= \left\|\varepsilon_{i}^{T}P_{i}B_{i}\right\|\left(\left\|\varepsilon_{i}^{T}P_{i}B_{i}\right\|\left\|\gamma_{i}^{a}\right\| + \exp\left(-c_{i}t^{2}\right)\left\|\gamma_{i}^{a}\right\| - \left\|\varepsilon_{i}^{T}P_{i}B_{i}\right\| + \exp\left(-c_{i}t^{2}\right)\right).$$
(35)

To prove that $\varepsilon_i^{\top} P_i B_i \gamma_i^a - \varepsilon_i^{\top} P_i B_i \hat{\gamma}_i^a \leq 0$, we need to prove that $\|\varepsilon_i^{\top} P_i B_i\| \|\gamma_i^a\| + \exp(-c_i t^2) \|\gamma_i^a\| -$

 $\begin{aligned} \left\|\varepsilon_{i}^{\top}P_{i}B_{i}\right\| &\exp\left(\hat{\rho}_{i}\right) \leqslant 0. \text{ Define } \upsilon_{i} = \kappa_{i}^{a}/\sigma_{\min}(P_{i}B_{i}),\\ \omega_{i} = 2\sigma_{\max}\left(P_{i}\right)\left(\left\|\beta_{i}\right\| + \left\|\Delta u_{i}\right\|\right)/\sigma_{\min}\left(\bar{Q}_{i}\right). \text{ Then,}\\ \text{define the compact sets } \Upsilon_{i} &\triangleq \left\{\left\|\varepsilon_{i}\right\| \leqslant \upsilon_{i}\right\} \text{ and}\\ \Omega_{i} &\triangleq \left\{\left\|\varepsilon_{i}\right\| \leqslant \omega_{i}\right\}. \text{ Considering Assumption 4, we}\\ \text{obtain that } \exp\left(-c_{i}t^{2}\right)\left\|\gamma_{i}^{a}\right\| \to 0. \text{ Hence, outside}\\ \text{the compact set } \Upsilon_{i} = \left\{\left\|\varepsilon_{i}\right\| \leqslant \upsilon_{i}\right\}, \exists t_{1}, \text{ such that}\\ \varepsilon_{i}^{\top}P_{i}B_{i}\gamma_{i}^{a} - \varepsilon_{i}^{\top}P_{i}B_{i}\hat{\gamma}_{i}^{a} \leqslant 0, \forall t \geq t_{1}; \text{ outside the compact set}\\ \Omega_{i}, -\sigma_{\min}\left(\bar{Q}_{i}\right)\left\|\varepsilon_{i}\right\|^{2} + 2\sigma_{\max}\left(P_{i}\right)\left\|\varepsilon_{i}\right\|\left\|\beta_{i}\right\| \leqslant 0. \text{ Therefore,}\\ \text{ combining (34), (35) and (32), we obtain, outside the compact set}\\ \text{ set } \Upsilon_{i} \cup \Omega_{i}, \forall t \geq t_{1}, \end{aligned}$

$$\dot{V}_i \leqslant 0. \tag{36}$$

Hence, by the LaSalle's invariance principle, ε_i is UUB. We conclude that Δ_o and ε_i are UUB, consequently, e_c is UUB. Furthermore, based on Lemma 2, under the satisfaction of safety constraints (18), we obtain that $h_{S_{ij}} \leq 0$. That is $||x_i - x_j|| \ge d_s$. This completes the proof.

IV. NUMERICAL SIMULATIONS

In this section, we validate the proposed SAAR control strategies through numerical simulations of a heterogeneous autonomous MAS under EU-FDI attacks on both CIL and OL. Fig. 2 illustrates the communication topology among the agents. As seen, the autonomous MAS consists of four followers (agent 1 to 4) and four leaders (agent 5 to 8), with the dynamics of the followers and the leaders modeled by the following equations:

$$\dot{x}_{1} = \begin{bmatrix} -2 & 1 & 0 \\ 0 & -3 & 1 \\ 0.5 & 0 & -1 \end{bmatrix} x_{1} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} u_{1},$$

$$\dot{x}_{2} = \begin{bmatrix} -1 & 0 & 0.5 \\ 0 & -2 & 1 \\ 0.5 & 0 & -0.5 \end{bmatrix} x_{2} + \begin{bmatrix} 0.5 & 1 & 0 \\ 1 & 0.5 & 0 \\ 0 & 0 & 1 \end{bmatrix} u_{2},$$

$$\dot{x}_{3} = \begin{bmatrix} -1 & 1 & 0 \\ 0 & -3 & 1 \\ 0 & 0.5 & -1 \end{bmatrix} x_{3} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} u_{3},$$

$$\dot{x}_{4} = \begin{bmatrix} -1 & 0.5 & 0 \\ 0.5 & -1.5 & 0.5 \\ -0.5 & 0 & -2 \end{bmatrix} x_{4} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} u_{4},$$

$$\dot{x}_{5,6,7,8} = \begin{bmatrix} 0 & -2 & 1 \\ 2 & 0 & 1 \\ -1 & -1 & 0 \end{bmatrix} x_{5,6,7,8}.$$

Fig. 2: Communication topology.

We inject the following EU-FDI attack signals on the CIL and OL:

$$\begin{split} \gamma_1^a &= \begin{bmatrix} 5.5e^{0.11t} \\ 1.5e^{0.23t} \\ -6.6e^{0.08t} \end{bmatrix}, \quad \gamma_1^{ol} = \begin{bmatrix} -1.2e^{0.40t} \\ 1.5e^{0.61t} \\ 2.7e^{0.15t} \end{bmatrix}, \\ \gamma_2^a &= \begin{bmatrix} 2.3e^{0.15t} \\ -8.7e^{0.42t} \\ 14.5e^{0.14t} \end{bmatrix}, \quad \gamma_2^{ol} = \begin{bmatrix} 3.3e^{0.06t} \\ -2.2e^{0.27t} \\ -1.7e^{0.21t} \end{bmatrix}, \\ \gamma_3^a &= \begin{bmatrix} 7.6e^{0.35t} \\ -9.7e^{0.20t} \\ -17.2e^{0.06t} \end{bmatrix}, \quad \gamma_3^{ol} = \begin{bmatrix} 2.8e^{0.24t} \\ -5.0e^{0.04t} \\ -1.8e^{0.08t} \end{bmatrix}, \\ \gamma_4^a &= \begin{bmatrix} -2.9e^{0.16t} \\ 5.2e^{0.15t} \\ -7.7e^{0.10t} \end{bmatrix}, \quad \gamma_4^{ol} = \begin{bmatrix} -5.2e^{0.04t} \\ 2.4e^{0.13t} \\ -2.1e^{0.18t} \end{bmatrix}. \end{split}$$

These attack signals, which grow exponentially over time, are crafted to evaluate the system's ability to adapt and maintain resilience in the face of evolving adversarial conditions. Select $U_{1,2,3,4} = I_2$, and $Q_{1,2,3,4} = 3I_2$. The controller gain matrices K_i and H_i are found by solving (14)-(16).

We choose $d_s = 0.2$ for collision avoidance. The performance of the proposed SAAR control strategies, considering these safety constraints, is demonstrated through a set of comparative simulation results contrasted with non-SAAR standard control protocols [20]. The three sub-figures in Fig. 3 illustrate the initial three-dimensional (3D) positions of the agents and compare the system responses under standard control and SAAR control following the attacks. Both EU-FDI attacks on the OL and CIL are initiated at t = 3 s. Fig. 3(a) depicts the initial positions of the agents, while Fig. 3(b) presents the agents' 3D positions at t = 4.50 s under the standard control approach, where the containment objective is not achieved post-attack. In contrast, Fig. 3(c) displays the agents' 3D positions at t = 4.46 s under the SAAR control approach, demonstrating that the UUB containment objective is preserved despite the attacks.

Fig. 4(a) illustrates the evolution of the containment error e_c under conventional control. The dimensional components of e_c diverge, indicating a failure in achieving containment. In contrast, Fig. 4(b) depicts the system response under SAAR control following the injection of the attacks. While brief spikes in the error reflect the system's transient response to the attacks, the SAAR controller quickly compensates, causing the errors to stabilize and enter a steady state. This behavior demonstrates the resilience of the SAAR controller in maintaining UUB containment performance by effectively mitigating the impact of EU-FDI attacks on both CIL and OL.

Fig. 5 depicts the evolution of the distances between followers, denoted as d_{12} , d_{13} , d_{14} , d_{23} , d_{24} , and d_{34} , over time. Following the attacks, a brief spike in the distances is observed as the system experiences a transient response. However, the SAAR controller quickly compensates, and the distances stabilize shortly after, ensuring collision avoidance among followers. Fig. 4(b) and Fig. 5 show that the system successfully maintains safety and achieves the UUB containment under EU-FDI attacks on both OL and CIL, validating the effectiveness

Fig. 3: Leader-follower 3D motion evolution: (a) 0 s snapshot. (b) Snapshot after the attacks using the standard control. (c) Snapshot after the attacks using the SAAR control.

Fig. 4: Containment errors: (a) using conventional control (b) using SAAR control.

of the proposed SAAR defense strategies.

V. CONCLUSION

In this study, we have developed a SAAR control framework to address the challenges posed by EU-FDI attacks on autonomous MASs. We have introduced an attack-resilient OL and integrated safety constraints through QP to achieve collision avoidance, ensuring system safety even under attack. Additionally, a compensational signal has been designed to counteract the impact of EU-FDI attacks on the CIL. Rigorous Lyapunov stability analysis and 3D simulations have demonstrated the SAAR controller's effectiveness in maintaining both safety and resilience in practical autonomous MAS environments, where leader agents span safe regions to guide heterogeneous follower agents while addressing collision avoidance.
