Abstract

Large Language Models (LLMs) have demonstrated remarkable performance across a wide range of tasks by understanding input information and predicting corresponding outputs. However, the internal mechanisms by which LLMs comprehend input and make effective predictions remain poorly understood. In this paper, we explore the working mechanism of LLMs in information processing from the perspective of Information Bottleneck Theory. We propose a non-training construction strategy to define a task space and identify the following key findings: (1) LLMs compress input information into specific task spaces (e.g., sentiment space, topic space) to facilitate task understanding; (2) they then extract and utilize relevant information from the task space at critical moments to generate accurate predictions. Based on these insights, we introduce two novel approaches: an Information Compression-based Context Learning (IC-ICL) and a Task-Space-guided Fine-Tuning (TS-FT). IC-ICL enhances reasoning performance and inference efficiency by compressing retrieved example information into the task space. TS-FT employs a space-guided loss to fine-tune LLMs, encouraging the learning of more effective compression and selection mechanisms. Experiments across multiple datasets validate the effectiveness of task space construction. Additionally, IC-ICL not only improves performance but also accelerates inference speed by over 40%, while TS-FT achieves superior results with a minimal strategy adjustment^{1 2}.

1 Introduction

Large Language Models (LLMs) have achieved remarkable success in natural language processing (NLP), demonstrating exceptional performance

across a wide range of tasks such as text generation, machine translation, and sentiment analysis. By understanding input information and predicting corresponding outputs, LLMs have shown strong capabilities in handling complex tasks. However, despite their impressive real-world performance, the internal mechanisms by which LLMs comprehend input and make accurate predictions remain largely unexplored.

In this paper, we investigate the information processing mechanisms of Large Language Models (LLMs) from the perspective of Information Bottleneck Theory³. We propose a non-gradient-based task space detection strategy, which helps trace the internal information flow within LLMs. Using this strategy, we investigate the information flow across layers of LLMs during comprehension and prediction phase. During the understanding phase, LLMs compress input information into specific task spaces. In the prediction phase, LLMs extract and integrate relevant information from the task spaces, decompressing it at critical moments to generate predictions. That is, LLMs perform task comprehension and prediction by compressing and decompressing information within specific task spaces. Further results show that while LLMs effectively compress high-quality information during the compression phase, they struggle to decompress it during the prediction phase, leading to suboptimal performance.

Based on these insights, we propose two novel methods derived from Information Bottleneck Theory: Information Compression-based Context Learning (IC-ICL) and Task-Space-guided Fine-Tuning (TS-FT). IC-ICL retrieves relevant examples and maps them into the task space, enhancing LLMs' decompression capabilities to improve pre-

²Our code will be released soon.

³Information Bottleneck Theory is a framework that optimizes the trade-off between retaining relevant information for a task and discarding redundant data by compressing the input.

diction accuracy. TS-FT constructs high-quality decompressed representations within the task space and employs a spatially-guided loss function to help LLMs learn better decompression strategies.

We validate our proposed methods through experiments on multiple datasets. The results demonstrate that IC-ICL significantly enhances reasoning accuracy while accelerating inference speed by over 40%. TS-FT enhances model performance through simple fine-tuning without the need for complex adjustments.

Overall, our contributions are as follows:

- We introduce a non-gradient-based task space detection method that aids in detecting information flow changes.
- We show that LLMs process tasks by compressing and decompressing information within task-specific spaces, exhibiting strong compression but weaker decompression abilities.
- We introduce an Information Compression-based Context Learning method that substantially improves performance while accelerating inference speed by 40%.
- We present a Task-Space-guided Fine-Tuning method that enhances LLMs’ information processing capabilities through a simple and effective space-guided loss function.

2 Information Detection for LLMs

In this section, we explore the information detection mechanisms within Large Language Models (LLMs) from the perspective of Information Bottleneck Theory, focusing on how information is processed and optimized during task comprehension and prediction.

2.1 Task-Space-based Information Detection Strategy

We propose a task-space-based strategy for detecting information flow in LLMs, which leverages the concept of compressing input information into task-specific spaces for efficient processing.

The task space is composed of multiple basic vectors, each constructed from the features that best represent the task at hand. For instance, in emotion classification, the most representative feature is the emotion categories. Therefore, we construct the emotional categories involved in the task as basic

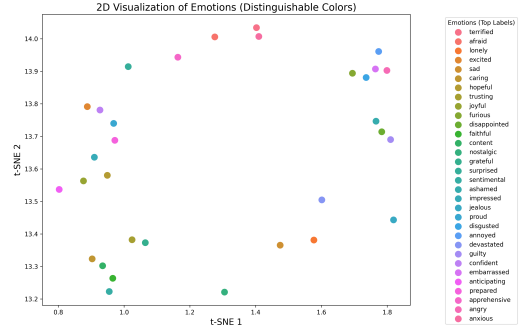

Figure 1: 2D visualization of the emotion space.

dimension vectors. Similarly, for topic classification task, we construct the topic types as the basic vectors.

For simplicity, we use emotion categories as an example to describe the construction process. For an emotion category $e_i \in E$, such as “joyful”, we construct the input pairs shown in Table 1, i.e., positive-related prompt P^+ and negative-related prompt P^- . The negative-related prompt pairs consist of randomly sampled other emotion types, while the dialogue context is drawn from Empathetic Dialogues, containing dialogue statements with the emotion category e_i .

Based on these prompts, the LLM generates tokens y_t^+ and y_t^- at time step t .

$$Y^+ = LLM(y_t^+ | P^+, y_{<t}^+) \quad (1)$$

$$Y^- = LLM(y_t^- | P^-, y_{<t}^-) \quad (2)$$

We then extract the hidden vectors at layer l of the LLM, obtaining the positive-related hidden layer $h_{t,l}^+$ and the negative-related hidden vector representation $h_{t,l}^-$ for tokens y_t^+ and y_t^- at time step t . Following prior methods (Liu et al., 2024), we obtain the directional hidden vector representation H_t^l for time step t at layer l by subtracting the two vectors.

$$h_t^l = h_{t,l}^+ - h_{t,l}^- \quad (3)$$

Using the above method, we collect N_h direction vectors for the emotion type e_i . These vectors contain both the representation of the emotion type e_i and noise. To purify the emotion type representation, Principal Component Analysis (PCA) is applied, resulting in refined direction vectors $H_{e_i}^l$ for e_i . In this paper, we treat these direction vectors as dimensional vectors of the space elements.

$$H_{e_i}^l = PCA(H_{E_i}^l) \quad (4)$$

Table 1: Prompts for the task space of the emotion “joyful”

Prompt Type	Prompt Content
Positive-related Prompt	Infer the dialogue from the perspective of the emotion “ joyful ”. Dialogue Context: [Dialogue Context] Response Format: “Emotion: [Inferred Emotion]”
Negative-related Prompt	Infer the dialogue from the perspective of the emotion “ angry ”. Dialogue Context: [Dialogue Context] Response Format: “Emotion: [Inferred Emotion]”

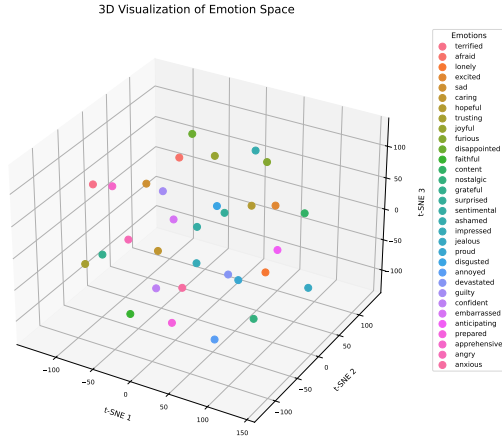

Figure 2: 3D visualization of the emotion space.

Figure 3: Visualization of emotion similarity

2.2 Constructing Task Spaces

The construction of task spaces is central to our approach, as it defines how information is organized and compressed to facilitate task comprehension and prediction. To validate the rationality of the task space, we visualize it for observation and analysis.

Figures 1 and 2 present the 2D and 3D visualizations of the emotion space after dimensionality reduction using t-SNE. The distribution of emotions in the figures shows that the emotions are fairly evenly distributed in the space, with similar emotions clustering closer together. For example, “terrified,” “afraid,” “anxious,” and “angry” are located closer to each other.

To more clearly illustrate the similarity between emotions, we also construct a heatmap of the cosine distances between emotions. The heatmap, shown in Figure 3, calculates the cosine distance between pairs of emotions, where a brighter color indicates a smaller distance (i.e., higher similarity). The results explicitly show that more similar emotions, such as “excited” and “joyful”, have higher similarity scores, while more distinct emotions, such as “annoyed” and “caring”, exhibit lower similarity.

Based on these analyses and observations, the distribution of emotion categories in the space appears to be both uniform and reasonable, supporting the validity of the emotion space.

2.3 Information Compression in Understanding

During the understanding phase, LLMs compress input information into task-specific spaces, retaining only the most relevant details for effective task processing.

2.3.1 Calculation of Mutual Information

Objective: The goal of this experiment is to verify the information state of input samples in the emotion space.

Hypothesis: The representation of the samples compresses toward a specific emotion space.

Steps: (1) **Sample Representation.** We selected n samples S from the Empathetic Dialogue dataset for mutual information statistical experiments. For sample s_i , its hidden layer representation h_s^l at the l -th layer is obtained by inputting it into the LLMs.

$$h_{s_i}^l = [h_0^l, \dots, h_j^l, \dots, h_N^l] \quad (5)$$

$$h_{s_i}^l \in R^{d \times N} \quad (6)$$

(2) **Emotion Space Representation.** For sample s_i , we define its ground-truth emotion label as e_{s_i} . To observe the sample’s state in the emotion space, we define multiple emotion spaces: $e_{s_i}^{top1}$, $e_{s_i}^{top2}$, $e_{s_i}^{top d_k}$, and $e_{s_i}^{top d_e}$.

$$e_{top} = Top_{d_k}^{cosine}(e_{s_i}, e_j) \quad (7)$$

$$e_{d_k} = \frac{1}{d_k} \sum_{top_j=1}^{d_k} e_{top_j} \quad (8)$$

Here, $Top_{d_k}^{cosine}$ is a function that sorts emotions based on cosine similarity and selects the top d_k most similar emotion types. $e_j \in E$ represents the emotions from the set of all emotion types E . When $d_k = 1$, the emotion space at the l -th layer corresponds to the base vector derived from the ground-truth emotion label. When $d_k \neq 1$, the emotion space at the l -th layer is the mean of the d_k nearest neighbors (including the sample’s own label) based on cosine distance.

(3) **Projection to Emotion Space.** For the j -th token’s representation at the l -th layer, h_j^l , we project it onto the corresponding emotion space $e_{d_k}^{l,top}$:

$$h_j^{p,l} = \frac{h_j^l \cdot e_{d_k}^{l,top}}{|e_{d_k}^{l,top} \cdot e_{d_k}^{l,top}|} e_{d_k}^{l,top} \quad (9)$$

For the N tokens in sample s_i during the comprehension process, we sum the projected representations $h_j^{p,l}$ to obtain the overall projection of the sample:

$$h_{s_i}^{p,l} = \sum_{j=1}^N h_j^{p,l} \quad (10)$$

Mutual Information Estimation. Mutual Information (MI) measures the dependency between two random variables X and Y . It quantifies the reduction in uncertainty of one variable given the other. The mutual information is defined as:

$$I(X; Y) = \int \int p(x, y) \log \frac{p(x, y)}{p(x)p(y)} dx dy, \quad (11)$$

where $p(x, y)$ is the joint probability density function of X and Y , and $p(x)$, $p(y)$ are their respective marginal probability densities.

In practice, exact computation of mutual information is infeasible as the true probability distributions are unknown. Therefore, we employ K-Nearest Neighbors (KNN)-based methods to approximate the densities. Using these approximations, the MI can be expressed as:

$$I(X; Y) \approx \frac{1}{N} \sum_{i=1}^N \log \frac{\hat{p}(x_i, y_i)}{\hat{p}(x_i)\hat{p}(y_i)}, \quad (12)$$

where $\hat{p}(x_i, y_i)$, $\hat{p}(x_i)$, and $\hat{p}(y_i)$ are the estimated joint and marginal probabilities for the samples x_i and y_i .

Using the method described above, the mutual information $I(h_{s_i}^{p,l}; e_{d_k}^{l,top})$ between the sample s_i and the emotion space $e_{d_k}^{l,top}$ at the l -th layer can be obtained. At the same time, we also computed the mutual information $I(h_{s_i}^{p,l}; h_{s_i}^{p,0})$ between the l -th layer and the 0-th layer.

2.3.2 Analysis of Results

According to information bottleneck theory, information during the comprehension process should move away from the initial space and towards the target emotion space. That is, the mutual information between the l -th layer’s hidden state and the 0-th layer’s hidden state should gradually decrease, while the mutual information with the target emotion space should gradually increase.

Figure 4 shows the variation in mutual information of the l -th layer’s hidden state in the ground-truth emotion space, i.e., with $d_k = 1$. According to the results, the mutual information in the earlier layers of the LLM fluctuates significantly. This is primarily because the shallow layers of LLMs mainly process basic information such as syntax and grammar. However, after layers 12 to 28, the mutual information between the hidden state z and the input x gradually decreases, while the mutual information with the target emotion space y gradually increases. This suggests that LLMs compress the input content towards a specific emotion space.

Figures 5 and 6 show the variation in mutual information across a broader range of emotion spaces, i.e., with $d_k = 1$. The results also exhibit the same trend.

Specifically, we plotted the mutual information variation for the widest emotion space, with $d_k = 32$, as shown in Figure 7. We observe that

Figure 4: Information variation of LLMs in the ground-truth emotion space.

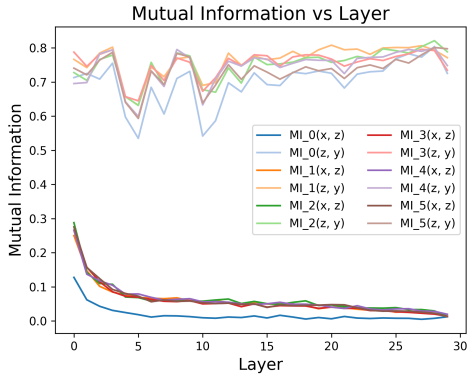

Figure 5: Information Variation of LLMs in the Emotion Space with $d_k = 2$

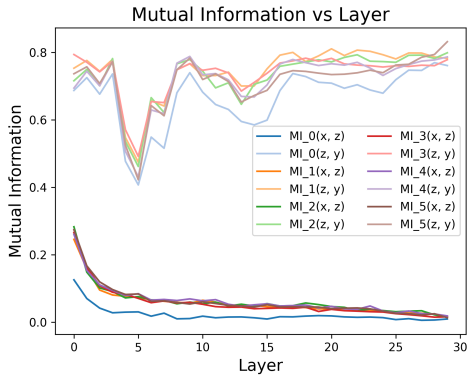

Figure 6: Information Variation of LLMs in the Emotion Space with $d_k = 5$

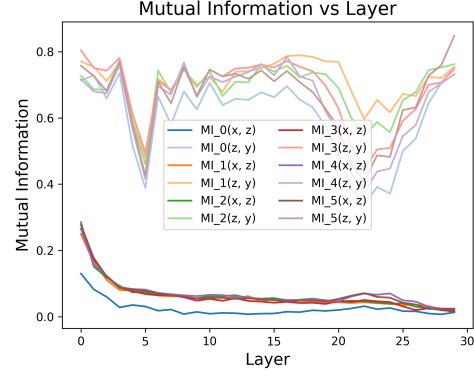

Figure 7: Information Variation of LLMs in the Emotion Space with $d_k = 32$

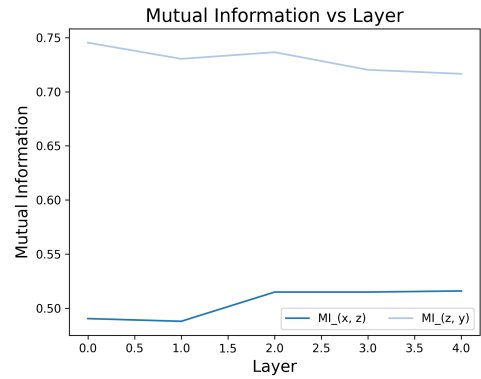

Figure 8: Information Variation of LLMs in the Emotion Space with $d_k = 32$

the mutual information continues to change in this space. Combining data from all emotion spaces, this suggests that LLMs actually compress information towards an emotion space closer to the ground-truth, rather than compressing information across the entire emotion space.

2.4 Information Decompression in Prediction

In the prediction phase, LLMs decompress the relevant information from task spaces to generate accurate predictions, highlighting the challenges and limitations in the decompression process.

2.4.1 Information Measurement During the Prediction

Objective: Explore the decompression mechanism of LLMs. **Hypothesis:** LLMs decompress information from the emotion space at the key time step t to make predictions.

Steps: We tested the mutual information between the LLMs' hidden state at time step t and the hidden state at time step 0, as well as the mutual information with the emotion space ($es_{d_k}^{top}$). Here,

Figure 9: Information Variation of LLMs in the Emotion Space with $d_k = 32$

the hidden state at time step 0 corresponds to the LLM sample s_i 's hidden state representation in the emotion space, while the hidden states at other time steps correspond to the hidden representations during the generation process. The objective of this experiment is to verify the information variation of LLMs at each time step during the generation process.

Figure 8 shows the variation in mutual information between the LLM's hidden state at time step t and the average emotion space of s_i 's comprehension content. Figure 9 shows the variation in mutual information between the LLM's hidden state at time step t and the overall emotion space of s_i 's comprehension content. The results indicate that during the generation process, LLMs continuously decompress information from the emotion space to generate tokens.

2.4.2 Detection of Key Prediction Steps

To further investigate whether LLMs rely on certain key time steps t during prediction, we conducted additional experiments.

Objective: Explore the key time steps during LLMs' prediction process.

Hypothesis: There exist key time steps t that significantly affect the prediction results.

Steps: At each time step t , we directly add or subtract the ground-truth emotion space to the LLM's hidden state to examine the effect of each time step. The 0-th step represents the information representation during the understanding phase, while steps 1-5 represent the information representations during the generation process.

The experimental results are shown in Table 1. The results indicate that the most crucial time steps are the 0-th, 4-th, and 5-th steps. Modifying the

Steps	Add/Sub	Acc	F1
Baseline	-	35.35	26.24
Step 0	Addition		
	Subtract	14.13	11.13
Step 0-3	Addition		
	Subtract	14.13	11.13
Step 4-5	Addition	81.92	69.91
	Subtract	11.41	7.81
Step 0,4-5	Addition		
	Subtract	3.006	2.06

Table 2: Experimental results of modifying hidden states at t Time Steps.

LLM's hidden state at these time steps significantly altered the prediction accuracy. The impact of the 0-th step is mainly due to the fact that LLMs are processing and understanding the input sample s_i at this point. The significant influence of the 4-th and 5-th steps is mainly because LLMs decompress key information at these moments.

In general, when LLMs are understanding the input information at $t=0$, removing the hidden state's representation in the emotion space significantly reduces emotional accuracy. This is mainly because LLMs rely on decompressing the state at the understanding stage to make accurate predictions. Removing the hidden state's representation in the emotion space at this point makes it difficult for the model to decompress effective information. On the other hand, adding the emotion space projection to the hidden state does not have a significant impact on the results, suggesting that LLMs have already effectively compressed information in the emotion space.

At the prediction stage ($t=4,5$), both adding and subtracting the hidden state's representation in the emotion space significantly affect the results. This indicates that there are key moments during the prediction process when LLMs rely on specific emotional representations.

Furthermore, when the hidden state is added to the emotion space, the LLMs' performance greatly improves. This suggests that LLMs struggle to decompress high-quality information on their own, and better decompression requires additional strategies or support to effectively extract the desired information.

3 Method

To further enhance LLMs’ ability to decompress information, we propose two models: Information Compression-based Context Learning and Task-Space-guided Fine-Tuning.

3.1 Information Compression-based Context Learning

We first used a pre-trained model, *RoBERTa_{large}*, to retrieve the top k_s most similar samples.

$$p_{s_i}, v_{s_i} = \text{RoBERTa}_{large}(s_i), \quad (13)$$

$$o_{m_i} = \text{Cosine}(v_{s_i}, v_{m_i}^s), m_i \in n_d, \quad (14)$$

$$s_j = \text{Top}_{k_2}(o_1, o_2, \dots, o_{m_i}), j \in [1, k_2], \quad (15)$$

Next, we extracted the emotion labels of these k_s samples and converted them into emotion vector representations. These vectors were then weighted by w_e and added to the hidden layers of the LLMs.

$$h_e^l = \sum_{n_i=1}^{k_1} w_e * h_{e_{n_i}}^l \quad (16)$$

$$\tilde{h}^l = h^l + h_e^l \quad (17)$$

Intuitively, since the weight w_e is fixed, the introduction of k_2 direction vectors, each added with equal weight, may not accurately provide the model with a high-quality hidden state. Therefore, we further refined the adjustment of these direction vectors.

$$O_{E_i}^l = \tilde{h}^l + h_{E_i}^l \quad (18)$$

$$g_{E_i} = \text{Softmax}(\tilde{h}^l O_{E_i}^l) \quad (19)$$

$$\bar{h}^l = \tilde{h}^l + w_e^a(g_{E_i} h_{E_i}^l) \quad (20)$$

Finally, we prompt the LLM to predict the emotion category of the dialogue context.

$$e_i = \text{LLM}(s_i) \quad (21)$$

$$Y = \text{LLM}(y_t | s_i, e_i) \quad (22)$$

3.2 Task-Space-guided Fine-Tuning

For the sample s_i , this section transforms its corresponding emotion label e^* into the direction vector at the l -th layer. Then, it is added to the hidden layer of the LLMs at the l -th layer to obtain a higher-quality hidden layer.

$$h^{*,l} = h^l + h_{e^*}^l \quad (23)$$

To ensure that the hidden layers converge towards a better-quality direction during training, we design a mean squared error (MSE) loss.

$$\mathcal{L}_{mse}^l = \frac{1}{d} \sum_{i=1}^d (h_i^{*,l} - h^l)^2 \quad (24)$$

$$\mathcal{L}_{mse} = w_{mse} * \sum_{l=1}^L \mathcal{L}_{mse}^l \quad (25)$$

where w_{mse} is a hyperparameter, and n and L are the dimensionality and number of layers of the LLMs, respectively.

For s_i , we also employ cross-entropy as the generation loss to encourage the LLMs to produce outputs in the corresponding response format.

$$\mathcal{L}_{LM} = - \sum_{t=1}^T \log p_{\theta}(x_t | x_{<t}, s_i) \quad (26)$$

where $x_{<t}$ is the previously generated text. Curriculum learning is used for optimization in this case. T represents the training time step.

Overall, we optimize the model based on the two losses:

$$\mathcal{L} = \mathcal{L}_{mse} + \mathcal{L}_{LM} \quad (27)$$

4 Results and Analysis

We validate the proposed method on the Empathetic Dialogues dataset, with the results shown in Table 3. The results indicate that the performance of the proposed IC-ICL method significantly outperforms the baseline. Along with improving inference performance, the inference speed also shows a substantial improvement. At the same time, the proposed TS-FT method also outperforms the baseline. The advantages of both methods show that enhancing the information decompression capability of LLMs further promotes their performance.

5 Related Work

In-Context Learning. Wei et al. (Wei et al., 2022) propose chain-of-thought prompting, which decomposes reasoning into sequential logical steps to enhance LLMs’ structured reasoning. Wang et al. (Wang et al., 2022) introduce self-consistency prompting, generating multiple reasoning paths and selecting the final answer through majority voting. Yao et al. (Yao et al., 2023) develop a tree-based approach that breaks complex problems into hierarchical sub-problems to improve reasoning accuracy.

Type	Models	Acc	F1	T
Prompt	Llama3.1 _{8b}	35.35	26.24	7:12
	ICL	29.55	32.45	14:17
	IC-ICL	43.69	36.35	7:37
Fine-Tuning	Llama3.1 _{8b}	54.48	53.94	-
	TS-FT	55.43	54.96	-

Table 3: Experimental results.

Besta et al. (Besta et al., 2023) propose a graph-based reasoning method that uses feedback loops to iteratively refine reasoning quality.

These methods rely on manually constructed examples, limiting their generalizability to diverse tasks. To address this, retrieval-based approaches select examples based on lexical features (Rubin et al., 2021; Agrawal et al., 2022; Luo et al., 2023), semantic similarity (Liu et al., 2021a), structural patterns (Levy et al., 2022), or other factors (Fu et al., 2022; Gonen et al., 2022; Drozdov et al., 2022). While these approaches show promising performance, they significantly slow down the inference process of LLMs due to the increased input length caused by the additional examples.

Fine-tuning. Fine-tuning is a key approach for adapting large language models (LLMs) to downstream tasks. While full model fine-tuning updates all parameters to achieve task-specific objectives (Devlin et al., 2019; Radford et al., 2019), it is computationally expensive. To improve efficiency, parameter-efficient methods have been proposed. Adapter-tuning adds small task-specific layers while freezing the main model (Houlsby et al., 2019; Pfeiffer et al., 2020). Prefix-tuning optimizes prefix vectors prepended to each layer’s input (Li and Liang, 2021; Lester et al., 2021), and LoRA modifies low-rank matrices within the model (Hu et al., 2021).

Other strategies include prompt-tuning, which fine-tunes continuous prompt embeddings (Liu et al., 2021b), and task-specific loss functions, such as contrastive or reinforcement learning objectives (Gao et al., 2021; Ouyang et al., 2022). These methods improve performance and efficiency, enabling the practical deployment of LLMs.

6 Conclusion

This paper investigates the information processing mechanisms of Large Language Models (LLMs) through the lens of Information Bottleneck Theory. We show that LLMs compress input into task-

specific spaces but struggle with decompression during prediction. Based on these insights, we propose two methods: Information Compression-based Context Learning (IC-ICL) and Task-Space-guided Fine-Tuning (TS-FT).

IC-ICL improves reasoning accuracy and accelerates inference by over 40%, while TS-FT enhances decompression capabilities through a simple loss function. Our experiments validate the effectiveness of these approaches, demonstrating significant performance improvements. These findings offer a deeper understanding of LLMs’ information processing and provide practical solutions for enhancing model performance.

Future work will explore refining these methods and applying them to other NLP tasks, further enhancing the efficiency and accuracy of LLMs.

Ethical Considerations

Regarding the potential ethical impacts of our work: (1) The dataset we use is EMPATHETIC-DIALOGUE, which is open source and does not involve any potential ethical risks. (2) The baseline models we use are also public and do not have potential moral impacts. Moreover, the components employed in our model are open-sourced or innovative and do not involve potential ethical risks.

Acknowledgments

We are grateful to the reviewers for their diligent evaluation and constructive feedback, which helped enhance the quality of this paper. We also appreciate the insightful discussions and comments from the authors, which stimulated valuable thinking and contributed significantly to the development of this research.
