# Distributed Framework Construction for Affine Formation Control

Huiming Li<sup>1</sup>, Hao Chen<sup>1,2</sup>, Xiangke Wang<sup>1</sup> Senior Member, IEEE, Zhongkui Li<sup>3</sup>, Senior Member, IEEE, Lincheng  $Shen<sup>1</sup>$ 

*Abstract***— In affine formation control problems, the construction of the framework with universal rigidity and affine localizability is a critical prerequisite, but it has not yet been well addressed, especially when additional agents join the formation or link/agent failures emerge. Motivated by this observation, we investigate the problem of constructing affine formation frameworks in three scenarios, including vertex addition, edge deletion and vertex deletion. Our approach starts from the original affine formation and uses geometric methods to locally adjust the structure of the weighted graph to describe the topology, so that the modified framework maintains the universal rigidity and affine localizability. Notably, the developed strategies only utilize local measurements and exhibit distributed characteristics, laying the foundation for applications in multi-agent systems. To demonstrate the compatibility with affine formation control proposals, we present a case study on affine formation tracking in a multi-UAV formation, demonstrating the effectiveness of our algorithms in constructing eligible frameworks in aforementioned scenarios. Moreover, a comparative simulations is also conducted to highlight the low time complexity of our distributed algorithm relative to the centralized optimization-based method.**

*Index Terms***— Affine formations, framework construction, rigidity maintenance, robot swarm**

#### I. INTRODUCTION

**A** FFINE formation control problem has recently attracted an increasing attention of scholars, which allows configuration transformations including translation, rotation, scaling, FFINE formation control problem has recently attracted an increasing attention of scholars, which allows configshearing and their combinations [1]–[3]. Various studies have been conducted to investigate the collaborative control scheme for affine formations, such as considering different system dynamics, e.g., linear dynamics [2], [4], unicycle models [5] and Euler-Lagrange models [6], or considering different operating modes, e.g., switching topologies [7], event-triggered

conditions [8], etc. Undoubtedly, the implementation of the above distributed cooperative control schemes heavily relies on the *framework* of affine formations, which is described by assigning coordinates in Euclidean space to the topology represented by a weighted graph [1]. A determined framework fixes the direction of information flow within a multiagent system, which directly influences the convergence of distributed collaborative control schemes. Moreover, in affine formations, the weighted graph used to describe the topology quantifies the strength of interaction among agents, which also affects the convergence speed of the control proposals. Most related studies used pre-designed frameworks, which generally suffers from inevitable changes during the mission execution process [9]. To address the potential various scenarios, the construction of affine formation frameworks is of great value and practical significance.

From a mathematical perspective, the problem of designing frameworks for multi-agent systems is usually transformed into the problem of constructing appropriate graph-related matrices (e.g., the bearing-based Laplacian matrix [10] and the stress matrix [11]), which not only reflect the underlying communication among agents but also affect the control gain of the close-loop system. Based on the theoretical analysis in [1], [2], there are two critical properties, *universal rigidity* and *affine localizability*, that need to be carefully considered to construct affine formation frameworks due to their direct impact on stabilizability. Up to now, some efforts have been put in to construct affine formation frameworks.

Starting with the rigidity required by an affine formation framework, a classic method, the Henneberg Construction (HC), is widely applied in many papers. HC was proposed in [12] to grow the minimally rigid graphs based on the graph structures and the properties of related matrices. Subsequently, lots of studies followed this idea to analyze how the graph rigidity changes after HCs, and how to obtain graphs with the desired characteristics through HCs. Connelly proved the universal rigidity is maintained after HCs [13], and a series of algorithms are proposed for building and reconstructing rigid graphs, not only the classical distance rigidity [14], but also the bearing rigidity  $[10]$ ,  $[15]$ ,  $[16]$ . In  $[17]$  and  $[18]$ , the issue of growing rigid tensegrity frameworks were addressed with the aid of HCs. Nevertheless, the affine localizability is rarely considered simultaneously in the related work, which requires the proposed framework construction algorithms to consider more constraints.

To meet specific constraints and address the framework

<span id="page-1-2"></span>construction issue, a normal idea is to establish an optimization problem to obtain a legal topology in which the minimum energy is spent among all the possible networks. In some existing works, the authors studied framework construction problem by using optimization methods to improve resilience [19], [20] and achieve stable coordination [21], [22]. In [11], Xiao et al. formulated the affine formation framework construction problem into a centralized mixed integer semidefinite programming (MISDP) problem to obtain the proper stress matrix for affine formation maneuvers while maximizing the convergence speed and minimizing the communication cost. The ready-to-use solver was applied to construct suitable frameworks, which had a significant impact on the computational time of the NP-hard mixed integer programming problem. However, all the researches mentioned above rely on global information (such as global positions required by [11]) of multi-agent systems and solve the optimization problem in a centralized way. On the one hand, limited by practical situations, global measurements and central agents are not guaranteed in some real robot systems, for example, only bearing measurements are available in [23] and the distributed architecture is necessary for large-scale swarms in [24]. On the other hand, the centralized optimization algorithm requires powerful computing resources, which adds difficulty to the update of the framework in real-time conditions. In [11], the computational cost of growing affine formation frameworks increased rapidly with the increase of swarm size. Accordingly, beyond existing research, it is a meaningful and challenging issue to construct affine formation frameworks using local measurements in a distributed way.

Motivated by these observations, we investigate the distributed strategies to construct affine formation frameworks to provide fundamental support for formation control strategies. Different from centralized approaches, we design the framework construction strategies based on HCs by using local measurements in three specific scenarios. Theoretical analysis and simulations are provided to demonstrate that our algorithms preserve not only universal rigidity but also affine localizability to stabilize affine formations. The main contributions of this paper can be summarized as follows.

- (1) We propose distributed strategies to construct affine formation frameworks to address various application scenarios, including vertex addition, edge deletion and vertex deletion. Our approaches do not rely on global measurements, making it well-suited for extensive application in multi-agent systems due to their distributed nature.
- (2) We provide comprehensive theoretical analysis on the mathematical conditions of our proposed framework construction strategies to guarantee the characteristics of affine formations, namely universal rigidity and affine localizability. The presented simulations demonstrate the low time complexity and the widespread practicality in multi-agent systems.

The remainder of this paper is organized as follows. We provide foundational definitions and lemmas in Section [II.](#page-1-0) In Section [III,](#page-3-0) we address the key problem and propose distributed algorithms on affine formation constructions. Then, we provide some discussions about our strategies in Section [IV.](#page-8-0) The effectiveness is validated by simulations in Section [V.](#page-8-1) The conclusions are summarized in Section [VI.](#page-10-0)

**Notation :** Throughout the paper, the partial order  $A \succ 0$  $(A \succeq 0)$  means that the matrix A is positive definite (positive semi-definite).

#### II. PROBLEM FORMULATION

<span id="page-1-0"></span>In this section, we introduce some basic definitions and supportive lemmas, and then establish the framework construction problems to be studied.

#### *A. Affine Formation*

We model the interaction topology of a  $n$ -agent system as a simple undirected graph  $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ , where  $\mathcal{V} = \{v_1 \cdots v_n\}$ is the set of vertices,  $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$  is the set of edges, and  $|\mathcal{E}| = m$ . An edge  $e_{ij}$  exists if and only if there is a bidirectional interaction between vertex  $v_i$  and  $v_j$ . Hence, the communication neighbor set of vertex  $v_i$  is denoted by  $\mathcal{N}_i := \{v_j \in \mathcal{V} \mid e_{ij} \in \mathcal{E}\}\.$  Let  $p_i \in \mathbb{R}^d$  be the position of vertex  $v_i$ , and  $\boldsymbol{p} := \left[\boldsymbol{p}_i^T \cdots \boldsymbol{p}_n^T\right]^T$  describes the *configuration* of the multi-agent system. We define a *framework* as a graph associated with p, i.e.,  $(\mathcal{G}, p)$ . The set of points  ${p_i}_{i=1}^n$  are called *affinely dependent* if there exist scalars  $\{a_i\}_{i=1}^{n-1}$  that are not all zero such that  $\sum_{i=1}^{n} a_i \mathbf{p}_i = 0$  and  $\sum_{i=1}^{n} a_i = 0$ , and *affinely independent* otherwise. A configuration  $p$  (or a framework  $(G, p)$ ) in  $\mathbb{R}^d$  is said to be in *general position* if no subset of the points  ${p_i}_{i=1}^n$  of cardinality  $d+1$  is affinely dependent. For example, a set of points in the plane are in general position if no three of them lie on a straight line. Considering the limited perception distance of agents, we define the perceived neighbors of agent i as  $\mathcal{N}_i^p := \{v_j \in$  $\mathcal{V} \mid \|\mathbf{p}_i - \mathbf{p}_j\| \le d_{per}$ , where  $d_{per}$  is the perception distance. We assume that all perceptible agents can communicate, i.e.,  $\mathcal{N}_i \subseteq \mathcal{N}_i^p$ .

We assign a *stress*, i.e., a set of scalars  $\{\varpi_{ij}\}_{(i,j)\in\mathcal{E}}$ , for all edges in the undirected graph. That is, a weight  $\varpi_{ij}$  is assigned for the edge  $e_{ij}$ , and  $\overline{\omega_{ij}} = \overline{\omega_{ji}}$ . An *equilibrium stress* is established if and only if  $\sum_{v_j \in \mathcal{N}_i} \varpi_{ij} (p_j - p_i) = 0$ holds for any vertex  $v_i$  in the framework  $(\mathcal{G}, p)$ . Its matrix form can be written as  $(\Omega \otimes I_d) p = 0$ , where the sign  $\otimes$ represents the Kronecker product and  $\Omega \in \mathbb{R}^{n \times n}$  is termed the *stress matrix*, defined as

$$
[\mathbf{\Omega}]_{ij} = \begin{cases} -\varpi_{ij} & \text{if } i \neq j \text{ and } v_j \in \mathcal{N}_i \\ 0 & \text{if } i \neq j \text{ and } v_j \notin \mathcal{N}_i \\ \sum_{k \in \mathcal{N}_i} \varpi_{ik} & \text{if } i = j \end{cases}
$$

The matrix  $I_d$  denotes the identity matrix in  $\mathbb{R}^d$ . The following lemma reveals the connection between the stress matrix and the rigidity.

<span id="page-1-1"></span>*Lemma 1 ( [25]):* Let  $(G, p)$  be an d-dimensional framework on *n* vertices in  $\mathbb{R}^d$ , for some  $d \leq n-2$ . Then  $(\mathcal{G}, \mathbf{p})$ is universally rigid if the following two conditions hold.

- (1)  $(\mathcal{G}, p)$  has a positive semi-definite (PSD) stress matrix  $\Omega$ with rank  $n - d - 1$ .
- (2) For each vertex  $v_i$ , the set  $\{p_i\} \cup \{p_j : v_j \in \mathcal{N}_j\}$  is in general position in  $\mathbb{R}^d$ .

Recently, the stress matrix has been widely applied to stabilize *affine formations* of multiple vehicles [1]–[3], [5]–[8], [26], [27]. Different from rigid formations, affine formations allow the rotation, translation, scaling, shearing and combinations of them, which have a great advantage in enhancing formation maneuverability. In the affine formation control scheme, the leader-follower structure is adopted naturally. Let  $n_l$  vertices  $V_l = \{v_1, \dots, v_{n_l}\}\$  be the leaders, and the remaining  $n_f = n - n_l$  vertices in the framework be the followers, denoted by  $V_f = V \backslash V_l$ . Define a constant configuration in general position as *nominal configuration*  $\boldsymbol{r} = \left[ \boldsymbol{r}_l^T, \boldsymbol{r}_f^T \right]^T$ , where  $\boldsymbol{r}_l$  represents the configuration of  $n_l$ leaders and  $\vec{r}_f$  describes the configuration of the followers. Accordingly, the *nominal framework* is denoted by  $(\mathcal{G}, \mathbf{r})$ , and the time-varying target configuration is expressed as  $\mathbf{p}^*(t) = [\mathbf{I}_n \otimes \mathbf{A}(t)] \mathbf{r} + \mathbf{1}_n \otimes \mathbf{b}(t)$ , where the invertible matrix  $A(t) \in \mathbb{R}^{d \times d}$  and translation vector  $b(t) \in \mathbb{R}^d$  are continuous on  $t$ . In this paper, we assume that the nominal framework  $(\mathcal{G}, r)$  satisfy  $n \geq d + 2$ , where  $n_l$  agents that affinely span (refer to [2]  $) \mathbb{R}^{d}$  are selected as leaders. Since the affine span of  $\mathbb{R}^d$  requires at least  $d+1$  points,  $n_l = d+1$  is assumed to be held, following the analysis in [2], [5].

*Lemma 2 ( [2]):* Assume that the nominal formation  $(\mathcal{G}, \mathbf{r})$ has a PSD stress matrix satisfying rank  $(\Omega) = n - d - 1$ . The following conditions are equivalent to each other

(i)  ${r_i}_{i=1}^n$  affinely span  $\mathbb{R}^d$ ;

(ii)  $\text{null}(\Omega) = \text{col}\left(\begin{bmatrix} r_1 & \cdots & r_n \ 1 & \cdots & 1 \end{bmatrix}\right)$  $1 \cdots 1$  $\left| \begin{array}{c} T \end{array} \right|$ 

 $\lceil$ Let the stress matrix  $\Omega$  associated with  $(\mathcal{G}, r)$  be  $\Omega =$  $\begin{bmatrix} \mathbf{\Omega}_{ll} & \mathbf{\Omega}_{lf} \\ \mathbf{\Omega}_{fl} & \mathbf{\Omega}_{ff} \end{bmatrix}$ , where  $\mathbf{\Omega}_{ll} \in \mathbb{R}^{n_l \times n_l}$ ,  $\mathbf{\Omega}_{lf} \in \mathbb{R}^{n_l \times n_f}$ ,  $\mathbf{\Omega}_{fl} \in \mathbb{R}^{n_l \times n_f}$  $\mathbb{R}^{n_f \times n_l}$ , and  $\overrightarrow{\Omega}_{ff} \in \mathbb{R}^{n_f \times n_f}$ . The definition of affine localizability is proposed in [2].

.

*Definition 1 (Affine localizability [2] ):* The nominal formation  $(\mathcal{G}, r)$  is affinely localizable by the leaders if for any  $p =$  $\left[\boldsymbol{p}_l^T, \boldsymbol{p}_f^T\right]$  $\in$   $\mathcal{A}(r)$ ,  $p_f$ can be uniquely determined by  $p_l$ , where  $\mathcal{A}(r)$  =  $\big\{\boldsymbol p: \boldsymbol p=(\boldsymbol I_n\stackrel{\circ}{\otimes}\boldsymbol A)\boldsymbol r+ \boldsymbol 1_n\otimes \boldsymbol b, \boldsymbol A\in\mathbb{R}^{d\times d}, \boldsymbol b\in\mathbb{R}^d\big\}.$ 

<span id="page-2-0"></span>*Lemma 3 ( [2]):* If the nominal formation  $(G, r)$  is universally rigid and  $\{r_i\}_{i=1}^n$  affinely span  $\mathbb{R}^d$ ,  $(\mathcal{G}, \bm{r})$  is affinely localizable if and only if  $\Omega_{ff}$  is nonsingular.

In the affine formation control scheme, a general dynamic of the closed-loop system is described by  $\delta_f = -\Omega_{ff} \delta_f$ , where  $\delta_f$  represents the followers' formation tracking error. Obviously, the properties of  $\Omega_{ff}$  greatly affect the convergence and stability of the system. Combined with Lemma [1](#page-1-1) and [3,](#page-2-0) it is easily deduced that  $\Omega_{ff}$  is positive definite, if  $(\mathcal{G}, r)$ is universally rigid and affinely localizable. Accordingly, to achieve desired affine formations, the following conditions are necessary for the nominal formation  $(\mathcal{G}, \mathbf{r})$ .

- (i) [*Universal Rigidity*] The stress matrix  $\Omega$  of  $(G, r)$  is PSD and rank $(\mathbf{\Omega}) = n - d - 1$ ;
- (ii) [*Affine Localizability*] The nominal formation  $(G, r)$  is affinely localized by the selected leaders.

Specifically, the first condition indicates that the framework  $(\mathcal{G}, r)$  is universally rigid [1], [13]. Combined with Lemma [2,](#page-1-2)

<span id="page-2-1"></span>Fig. 1. An unmanned aerial vehicle formation maneuvers through complicated environments. Three scenarios are presented, including vertex addition, edge deletion and vertex deletion.

the null space of  $\Omega$  is obtained. The second condition implies  $\Omega_{ff}$  is positive definite to stabilize the formation tracking error. Accordingly, the universal rigidity and affine localizability are two key properties to ensure the feasibility of the framework under various affine formation control schemes, which are also the focus of our subsequent theoretical analysis.

### *B. Problem Statement*

In a robot swarm, due to the time-varying target tasks and complex environments, the configuration and topology are usually not constant. It is crucial to flexibly generate and reconstruct framework according to different situations. Take the scenario in Fig. [1](#page-2-1) as an example, when a group of unmanned aerial vehicles (UAVs) pass through dense buildings or woods, situations including UAV joining, crashing, and communication disruptions may occur. From the perspective of graph theory, these situations can be described by the vertex addition, edge deletion and vertex deletion (corresponding to the UAV joining, communication disruption and crashing), respectively. The original topology of the swarm is changed, and even the inherent properties (such as connectivity, rigidity, etc.) are disrupted. Considering the supportive role of topology in cooperative control schemes, it is particularly crucial to timely construct the topology in various situations, which gives rise to the demand for framework construction strategies. Furthermore, considering the lack of understanding of the global states and measurements for perception-limited robots, the study of distributed algorithms is motivated in this paper.

In this paper, we investigate how to construct an affine formation framework to quickly adapt to different operating conditions. From the perspective of graph theory, the connections between vertices and the weights of edges are reshaped to guarantee the universal rigidity and affine localizability. Given an original affine formation framework  $(\mathcal{G}, p)$  with a stress matrix  $\Omega$ , design distributed algorithms to guarantee the universal rigidity and affine localizability of the obtained framework after adding vertices to  $(\mathcal{G}, p)$ , or removing vertices and edges from  $(\mathcal{G}, \mathbf{p})$ .

<span id="page-2-2"></span>*Assumption 1:* Suppose that the original framework  $(G, p)$ in general position is affinely localizable and universally rigid, where G contains a  $(d + 1)$ -lateration graph as a spanning subgraph.

A graph of *n* vertices is called a  $(d + 1)$ *-lateration* graph if there is a permutation  $\pi$  of the vertices,  $\pi(1), \pi(2), \cdots, \pi(n)$ ,

such that (i) the first  $(d+1)$  vertices,  $\pi(1), \cdots, \pi(d+1)$ , form a clique, and (ii) each remaining vertex  $\pi(j)$ , for  $j = (d+2), \cdots, n$ , is adjacent to  $(d+1)$  vertices in the set  $\{\pi(1), \pi(2) \cdots \pi(j-1)\}\$ . Based on Assumption [1,](#page-2-2) it is deduced that  $(G, p)$  admits a positive PSD stress matrix with rank  $(n - d - 1)$  [28]. The problems studied in this paper are established as follows.

*Problem 1 (Vertex Addition):* Given an affine formation framework  $(\mathcal{G}, p)$  and a new vertex  $v_u$ , design a strategy to link  $v_u$  with  $(\mathcal{G}, p)$  and then rearrange the stress so that the obtained framework  $(\mathcal{G}^+, p^+)$  is universally rigid and affinely localizable, where  $\mathcal{G}^+ = (\mathcal{V} \cup \{v_u\}, \mathcal{E}^+)$  and  $p^+ =$  $\left[\boldsymbol{p}^T, \ \boldsymbol{p}_u^T\right]^T$ .

*Problem 2 (Edge Deletion):* Given an affine formation framework  $(\mathcal{G}, p)$  with an edge  $e_{jk}$  (i.e.,  $j, k \in \mathcal{V}$ ,  $e_{jk} \in \mathcal{E}$ ), design a strategy to delete  $e_{ik}$  from  $\mathcal E$  while maintaining the universal rigidity and affine localizability of the obtained framework  $(\mathcal{G}_{ed}, \mathbf{p}_{ed})$ , where  $e_{jk} \notin \mathcal{E}_{ed}$ .

*Problem 3 (Vertex Deletion):* Given an affine formation framework  $(\mathcal{G}, p)$  with a specific vertex  $v_u$ , design a strategy to delete  $v_u$  from the vertex set V while maintaining the universal rigidity and affine localizability of the obtained framework  $(\mathcal{G}_{vd}, \mathbf{p}_{vd})$ , where  $v_u \notin \mathcal{V}_{vd}$ .

## <span id="page-3-0"></span>III. CONSTRUCTION OF AFFINE FORMATION FRAMEWORKS IN 2D

In this section, we aim to develop affine formation framework construction strategies to solve the problems proposed in Section [II.](#page-1-0) We consider  $d = 2$  in this section, and the methods are further extended to three-dimensional spaces in Section [IV.](#page-8-0)

#### <span id="page-3-7"></span>*A. Vertex Addition*

Given an affine formation  $(\mathcal{G}, p)$  and a new vertex  $v_u$ , our objective here is to merge  $v_u$  to the original framework  $(\mathcal{G}, p)$  with appropriate edges and weights, resulting in an new framework  $(\mathcal{G}^+, p^+)$  with universal rigidity and affine localizability. Naturally, the leaders in  $(\mathcal{G}, p)$  can be inherited by  $(\mathcal{G}^+, \mathbf{p}^+)$ , i.e,  $\mathcal{V}_l^+ = \mathcal{V}_l$ .

<span id="page-3-1"></span>*Assumption 2:* Given an affine formation  $(G, p)$  in general position, suppose that the perception distance of the new vertex  $v_u$  is large enough to ensure  $| \mathcal{N}_u^p | \geq 3$ , and the set  $\{p_u\} \cup$  $\{p_j : j \in \mathcal{N}_u^p\}$  is in general position.

We can choose three vertices in  $\mathcal{N}_u^p$ , denoted by  $v_i$ ,  $v_j$  and  $v_k$ . According to Assumption [2,](#page-3-1) we have that no three of  $v_i$ ,  $v_j$ ,  $v_k$  and  $v_u$  are collinear in  $\mathbb{R}^2$ . To generate an eligible affine formation framework, we add edges between  $v_u$  and all of  $v_i$ ,  $v_j$  and  $v_k$ , the resulting framework  $(\mathcal{G}^+, \mathbf{p}^+)$  is shown as in Fig. [2,](#page-3-2) where  $\mathcal{G}^+ = (\mathcal{V} \cup \{v_u\}, \mathcal{E} \cup \{e_{iu}, e_{ju}, e_{ku}\})$ and  $p^+ = \left[p^T, p_u^T\right]^T$ . To maintain the universal rigidity and affine localibility of  $(\mathcal{G}^+, p^+)$ , the stress in  $\mathcal{G}^+$  need to be rearranged, as discussed below.

Reorder the elements in  $V$  to place the selected three vertices  $v_i$ ,  $v_j$ ,  $v_k$  at the end, i.e.,  $\mathcal{V} \triangleq$  $\{\cdots, v_{i-1}, v_{i+1}, \cdots, v_{j-1}, v_{j+1}, \cdots, v_{k-1}, v_{k+1}, \cdots, v_i, v_j, v_k\}$ if  $i < j < k$ . The configuration p is also reordered based

<span id="page-3-2"></span>Fig. 2. An example of vertex addition. (a) The original framework  $(\mathcal{G}, p)$ in general position. (b) The obtained graph  $G^+$ , where the vertex  $v_u$ (labeled by a orange circle) and three edges are added.

on the index of  $V$ . Thus, for the graph  $G$ , the corresponding stress matrix  $\Omega$  can be described as below.

$$
\mathbf{\Omega} = \begin{bmatrix} -\frac{\mathbf{\Omega}^{P1}}{2} - \frac{1}{2} \frac{1}{\Omega_{ii}} - \frac{\mathbf{\Omega}^{P2}}{\Omega_{ij}} - \frac{1}{\Omega_{ik}} \\ (\mathbf{\Omega}^{P2})^T + \Omega_{ij} & \Omega_{jj} & \Omega_{jk} \\ \frac{1}{2} \Omega_{ik} & \Omega_{kj} & \Omega_{kk} \end{bmatrix},
$$
(1)

where  $\Omega$  is indexed based on the elements in  $\mathcal V$ . Inherited from Lemma [2,](#page-1-2) we have

<span id="page-3-4"></span>
$$
\left[\begin{array}{cccc}\boldsymbol{p}_1 & \cdots & \boldsymbol{p}_i & \boldsymbol{p}_j & \boldsymbol{p}_k\\1 & \cdots & 1 & 1 & 1\end{array}\right]\boldsymbol{\Omega}=\boldsymbol{0}.\tag{2}
$$

After adding a new vertex  $v_u$  and three edges,  $e_{iu}$ ,  $e_{iu}$ ,  $e_{ku}$ (as shown in Fig. [2\)](#page-3-2), the following equation [\(3\)](#page-3-3) is established based on the definition of a equilibrium stress.

<span id="page-3-3"></span>
$$
\varpi_{iu} (p_i - p_u) + \varpi_{ju} (p_j - p_u) + \varpi_{ku} (p_k - p_u) = 0, \tag{3}
$$

where  $\varpi_{iu}$ ,  $\varpi_{ju}$  and  $\varpi_{ku}$  are the weights of edges  $e_{iu}$ ,  $e_{ju}$ ,  $e_{ku}$ . The resulting stress matrix  $\Omega^+$  is expressed as follows.

$$
\mathbf{\Omega}^{+} = \begin{bmatrix} -\frac{\mathbf{\Omega}^{P1}}{1 - \mathbf{\Omega}_{ii}^{+}} - \frac{\mathbf{\Omega}^{P2}}{\mathbf{\Omega}_{ii}^{+}} - \frac{\mathbf{\Omega}^{P2}}{\mathbf{\Omega}_{ik}^{+}} - \frac{\mathbf{0}}{\mathbf{\Omega}_{ik}^{+}} - \frac{\mathbf{0}}{\mathbf{\Omega}_{uu}} \\ (\mathbf{\Omega}^{P2})^{T} \mid \mathbf{\Omega}_{ji}^{+} & \mathbf{\Omega}_{jj}^{+} & \mathbf{\Omega}_{jk}^{+} & -\omega_{ju} \\ \mathbf{0} & \mathbf{\Omega}_{ki}^{+} & \mathbf{\Omega}_{kj}^{+} & \mathbf{\Omega}_{kk}^{+} & -\omega_{ku} \\ \mathbf{0} & -\omega_{iu} & -\omega_{ju} & -\omega_{ku} & \omega_{uu} \end{bmatrix}, \quad (4)
$$

where  $\varpi_{uu} = \varpi_{iu} + \varpi_{ju} + \varpi_{ku}$ . Similarly, we have

<span id="page-3-5"></span>
$$
\left[\begin{array}{cccc}p_1 & \cdots & p_i & p_j & p_k & p_u\\1 & \cdots & 1 & 1 & 1 & 1\end{array}\right]\Omega^+=0.
$$
 (5)

Combining eqs. [\(2\)](#page-3-4)-[\(5\)](#page-3-5), we get

<span id="page-3-6"></span>
$$
\begin{bmatrix}\np_i & p_j & p_k & p_u \\
1 & 1 & 1 & 1\n\end{bmatrix}\n\begin{bmatrix}\n\Omega_{ii}^+ - \Omega_{ii} & \Omega_{ij}^+ - \Omega_{ij} & \Omega_{ik}^+ - \Omega_{ik} & -\varpi_{iu} \\
\Omega_{ij}^+ - \Omega_{ij} & \Omega_{jj}^+ - \Omega_{jj} & \Omega_{jk}^+ - \Omega_{jk} & -\varpi_{ju} \\
\Omega_{ik}^+ - \Omega_{ik} & \Omega_{jk}^+ - \Omega_{jk} & \Omega_{kk}^+ - \Omega_{kk} & -\varpi_{ku} \\
-\varpi_{iu} & -\varpi_{ju} & -\varpi_{ku} & \varpi_{uu}\n\end{bmatrix} = 0.
$$
\n(6)

Since  $v_u$  is not collinear with any two of  $v_i$ ,  $v_j$ ,  $v_k$ , the vectors  $(\mathbf{p}_i - \mathbf{p}_u)$ ,  $(\mathbf{p}_j - \mathbf{p}_u)$  and  $(\mathbf{p}_k - \mathbf{p}_u)$  are linearly independent, which implies that rank $(P_u) = 3$ . Accordingly, there exists a nonzero vector  $\phi = [\phi_1, \phi_2, \phi_3, \phi_4]^T$  satisfying  $P_u\phi = 0$ , which means

<span id="page-3-8"></span>
$$
\phi_1 + \phi_2 + \phi_3 + \phi_4 = 0, \ \phi_1 \mathbf{p}_i + \phi_2 \mathbf{p}_j + \phi_3 \mathbf{p}_k + \phi_4 \mathbf{p}_u = \mathbf{0}.
$$
 (7)

Accordingly, the matrix  $\Omega_u$  can be designed as below.

<span id="page-4-0"></span>
$$
\Omega_u = s\phi\phi^T = s \begin{bmatrix} \phi_1^2 & \phi_1\phi_2 & \phi_1\phi_3 & \phi_1\phi_4 \\ \phi_1\phi_2 & \phi_2^2 & \phi_2\phi_3 & \phi_2\phi_4 \\ \phi_1\phi_3 & \phi_2\phi_3 & \phi_3^2 & \phi_3\phi_4 \\ \phi_1\phi_4 & \phi_2\phi_4 & \phi_3\phi_4 & \phi_4^2 \end{bmatrix}, \quad (8)
$$

where s is a scaling parameter. Thus, we have  $\varpi_{iu}$  =  $-s\phi_1\phi_4$ ,  $\varpi_{ju} = -s\phi_2\phi_4$ ,  $\varpi_{ku} = -s\phi_3\phi_4$  and  $\varpi_{uu} = s\phi_4^2$ . Then, the corresponding stress matrix of the newly obtained framework  $(\mathcal{G}^+, p^+)$  is established as follows.

<span id="page-4-1"></span>
$$
\Omega^{+} = \underbrace{\left[\begin{array}{c} \mathbf{\Omega} & \mathbf{0}_{n \times 1} \\ \hline \mathbf{0}_{1 \times n} & 0 \end{array}\right]}_{\triangleq \mathbf{\Omega}_{a}} + \underbrace{\left[\begin{array}{c} \mathbf{0}_{-1} & \mathbf{0}_{-1} \\ \hline \mathbf{0}_{4 \times (n-3)} & 0 \end{array}\right]}_{\triangleq \mathbf{\Omega}_{b}}, \quad (9)
$$

where  $\Omega_u$  is described as eq. [\(8\)](#page-4-0) with  $s > 0$  and  $\Omega$  is the original stress matrix related to  $(\mathcal{G}, \mathbf{p})$ .

Next, a comprehensive theoretical analysis is provided to demonstrate the effectiveness of our strategy in constructing affine frameworks.

<span id="page-4-2"></span>*Theorem 1:* Under Assumption [1](#page-2-2)[-2,](#page-3-1) consider a new vertex  $v_u$  and an affine formation framework  $(\mathcal{G}, p)$  in  $\mathbb{R}^2$ . With a positive scaling parameter s, after adding three edges connecting the vertex  $v_u$  and the existing vertices  $v_i$ ,  $v_j$  and  $v_k$  to  $(\mathcal{G}, p)$ , the obtained framework  $(\mathcal{G}^+, p^+)$  is universally rigid and affinely localizable, with the corresponding stress matrix determined by [\(8\)](#page-4-0) and [\(9\)](#page-4-1).

*Proof:* Please refer to Appendix [I](#page-10-1) for details.

According to Theorem [1,](#page-4-2) the distributed nature of our proposed strategy is fully presented. Specifically, the global positions are not necessary based on the definition of a equilibrium stress [\(3\)](#page-3-3). The weight of an edge is determined by the relative position of the corresponding two endpoints when new edges are added to the framework, e.g.,  $\Omega_u$  in [\(8\)](#page-4-0). Accordingly, the local measurements are enough to update the stress matrix. Moreover, only several vertices are involved in the generation and reconstruction of affine formation frameworks, which supports the distributed execution of our methods. The construction of affine formation framework is solved by local measurements and communication, leading to the great application prospects in multi-robot systems. In fact, our algorithms can be integrated with most, if not all, distributed affine formation control schemes. A simulation is carried out in Section [V-B](#page-9-0) to verify the compatibility, where an example of formation tracking control law [5] is applied.

Furthermore, we present an algorithm for adding  $m$  vertices to  $(\mathcal{G}, p)$ , as shown in Algorithm [1.](#page-4-3) With Algorithm [1,](#page-4-3) we can easily grow the original affine formation framework to a larger scale, with a hierarchical structure. Intuitively, based on Theorem [1,](#page-4-2) we only use the local position measurements of a limited number of vertices, and incremental operations are executed to update the stress matrix. Different from [11], global position measurements and centralized optimization are not necessary in our proposed approach.

### <span id="page-4-3"></span>*B. Edge Deletion*

Note that removing an edge from the original framework  $(\mathcal{G}, p)$  is equivalent to adjusting the related weight to zero, Algorithm 1: Vertex Addition Algorithm in R 2

9 Return 
$$
(\mathcal{G}_{add}, \mathbf{p}_{add})
$$
 and  $\mathbf{\Omega}_{add}$ .

Fig. 3. Possible regions for placing four vertices in general position.

<span id="page-4-4"></span>without damaging the universal rigidity and affine localizability. Using the parameter s in eq. [\(8\)](#page-4-0), a natural idea is generated to eliminate a certain edge, as detailed below.

Take the removal of edge  $e_{jk}$  between vertex  $v_j$  and  $v_k$ in  $(\mathcal{G}, p)$  as an example. If we select two suitable vertices  $v_i$ and  $v_q$  in  $\mathcal{N}_j^p \cap \mathcal{N}_k^p$ , the vertices  $v_i$ ,  $v_j$  and  $v_k$  can form a triangle, and the regions of the fourth vertex  $v_q$  lies in can be labeled by  $a, \dots, g$ , as shown in Fig. [3.](#page-4-4) For four non-collinear vertices, we get a non-zero vector  $\phi$  satisfying  $\left. \begin{array}{ccc} \boldsymbol{p}_i & \boldsymbol{p}_j & \boldsymbol{p}_k & \boldsymbol{p}_q \ 1 & 1 & 1 & 1 \end{array} \right\rceil$  $\phi = 0$ . In the original framework  $(\mathcal{G}, p)$ , the stress matrix  $\Omega$  is indexed based on the elements in V, which are reordered such that  $v_i$ ,  $v_j$ ,  $v_k$ ,  $v_q$  are listed at the end. The entries involved in these four vertices in the stress matrix  $\Omega$  can be described as below.

$$
\mathbf{\Omega}_{v} = \left[ \begin{array}{cccc} \Omega_{ii} & \Omega_{ij} & \Omega_{ik} & \Omega_{iq} \\ \Omega_{ij} & \Omega_{jj} & \Omega_{jk} & \Omega_{jq} \\ \Omega_{ik} & \Omega_{jk} & \Omega_{kk} & \Omega_{kq} \\ \Omega_{iq} & \Omega_{jq} & \Omega_{kq} & \Omega_{qq} \end{array} \right].
$$
 (10)

After eliminating  $e_{jk}$ , the framework is described by  $(\mathcal{G}^-, \mathbf{p})$ , and the corresponding block matrix is established as follows.

$$
\Omega_v^- = \begin{bmatrix} \Omega_{ii}^- & \Omega_{ij}^- & \Omega_{ik}^- & \Omega_{iq}^- \\ \Omega_{ij}^- & \Omega_{jj}^- & 0 & \Omega_{jq}^- \\ \Omega_{ik}^- & 0 & \Omega_{kk}^- & \Omega_{kq}^- \\ \Omega_{iq}^- & \Omega_{jq}^- & \Omega_{kq}^- & \Omega_{qq}^- \end{bmatrix} .
$$
 (11)

Inspired by Eqs.  $(6)$  and  $(8)$ , we have

$$
\left[\begin{array}{ccc} p_i & p_j & p_k & p_q \\ 1 & 1 & 1 & 1 \end{array}\right] (\Omega_v - \Omega_v) = 0. \hspace{1cm} (12)
$$

<span id="page-5-0"></span>TABLE I THE SIGN OF THE WEIGHT OF THE EDGES CONNECTED TO  $v_a$ .

$$

$$
=\Omega_v+\frac{1}{\varpi_{qq}}\left[\begin{array}{cccc} \varpi_{iq}^2 & \varpi_{iq}\varpi_{jq} & \varpi_{iq}\varpi_{kq} & -\varpi_{iq}\varpi_{qq} \\ \varpi_{iq}\varpi_{jq} & \varpi_{jq}^2 & \varpi_{jq}\varpi_{kq} & -\varpi_{jq}\varpi_{qq} \\ \varpi_{iq}\varpi_{kq} & \varpi_{jq}\varpi_{kq} & \varpi_{kq}^2 & -\varpi_{kq}\varpi_{qq} \\ -\varpi_{iq}\varpi_{qq} & -\varpi_{jq}\varpi_{qq} & -\varpi_{kq}\varpi_{qq} & \varpi_{qq}^2 \\ \end{array}\right]
$$

where  $\varpi_{iq} = -s_{ed}\phi_1\phi_4$ ,  $\varpi_{jq} = -s_{ed}\phi_2\phi_4$ ,  $\varpi_{kq} =$  $-s_{ed}\phi_3\phi_4$  and  $\varpi_{qq} = s_{ed}\phi_4^2$ . To eliminate  $e_{jk}$ , the following equation is established

<span id="page-5-2"></span>
$$
\Omega_{jk} + \frac{\varpi_{jq}\varpi_{kq}}{\varpi_{qq}} = 0 \quad \Rightarrow s_{ed} = -\frac{\Omega_{jk}}{\phi_2\phi_3}.
$$
 (14)

To maintain the universal rigidity and affine localizability of the obtained framework  $(G^-, p)$ ,  $s_{ed} > 0$  is required based on Theorem [1,](#page-4-2) implying that

<span id="page-5-1"></span>
$$
\Omega_{jk}\varpi_{jq}\varpi_{kq} < 0. \tag{15}
$$

With a specific  $\Omega_{ik}$ , the sign of  $s_{ed}$  is determined by the signs of  $\varpi_{jq}$  and  $\varpi_{kq}$ , which depend on the relative positions among  $v_i$ ,  $v_j$ ,  $v_k$  and  $v_q$ . In detail, since  $v_q$  is not collinear with any two of  $v_i$ ,  $v_j$  and  $v_k$ , the vectors  $p_q - p_i$  and  $p_q - p_j$ can serve as a set of bases in  $\mathbb{R}^2$ . That is,

$$
\boldsymbol{p}_q - \boldsymbol{p}_k = k_1 \left( \boldsymbol{p}_q - \boldsymbol{p}_i \right) + k_2 \left( \boldsymbol{p}_q - \boldsymbol{p}_j \right), \qquad (16)
$$

where  $k_1$  and  $k_2$  are two real parameters that are not simultaneously zero. Combining with eq. [\(3\)](#page-3-3), we have

$$
\left(\varpi_{iq}+\varpi_{kq}k_1\right)\left(\mathbf{p}_q-\mathbf{p}_i\right)+\left(\varpi_{jq}+\varpi_{kq}k_2\right)\left(\mathbf{p}_q-\mathbf{p}_j\right)=\mathbf{0}.
$$

Accordingly, the following equations are deduced.

$$
\varpi_{iq} = -k_1 \varpi_{kq}, \varpi_{jq} = -k_2 \varpi_{kq}, \qquad (17)
$$

which mean  $\varpi_{iq}\varpi_{jq} = k_1k_2\varpi_{kq}^2$ ,  $\varpi_{iq}\varpi_{kq} = -k_1\varpi_{kq}^2$  and  $\overline{\omega}_{jq}\overline{\omega}_{kq} = -k_2\overline{\omega}_{kq}^2$ . When  $v_q$  lies in different regions, the signs of  $k_1$ ,  $k_2$  and the weights are listed in Table. [I,](#page-5-0) which serves as a guideline to determine whether the edge  $e_{ik}$  can be deleted without damaging universal rigidity and affine localizability. For example, if the weight of  $e_{jk}$  is positive, i.e.,  $\Omega_{jk} < 0$ , a vertex  $v_q$  in G lying in Region a,  $\mathfrak d$  or  $\mathfrak g$ should be chosen to ensure a positive  $s_{ed}$  based on [\(15\)](#page-5-1) and Table. [I.](#page-5-0) However, it is also possible that there are no vertices lying in these regions. Accordingly, based on whether  $e_{ik}$  can be eliminated through the rearrangement of edge weights in  $G$ , there are three possible cases presented as follows.

Case (1): There are two vertices  $v_i, v_q \in \mathcal{N}_j^p \cap \mathcal{N}_k^p$  to ensure that  $s_{ed}$  in [\(14\)](#page-5-2) is positive.

In this case, we can delete the edge  $e_{ik}$  directly to obtain a new framework  $(\mathcal{G}_{ed}, \mathbf{p}_{ed})$ , where  $\mathcal{G}_{ed} = (\mathcal{V}, \mathcal{E} \setminus \{e_{jk}\})$ ,  $p_{ed} = p$ . The stress matrix  $\Omega_{ed}$  for  $(\mathcal{G}_{ed}, p_{ed})$  is shown as below,

<span id="page-5-5"></span>
$$
\Omega_{ed} = \Omega + \left[ \frac{0_{(n-4)\times(n-4)}}{0_{4\times(n-4)}} \frac{1}{n} \frac{0_{(n-4)\times(4)}}{0_{u}} \right],
$$
 (18)

where  $\Omega_u = -\frac{\Omega_{jk}}{4\pi}$  $\frac{\partial^2 i}{\partial \phi^2} \phi \phi^T$ .

.

1  $\mathbf{I}$  $\mathbf{I}$  $\overline{1}$ 

The key point is to find the eligible vertices in  $\mathcal{N}_j^p \cap \mathcal{N}_k^p$ . In practice, the number of perceived neighbors is limited so that the local traversal is usually acceptable. For higher efficiency, we can also set a time upper limit on the search for suitable neighbors. If we cannot find proper neighbors within the specified time, a relay strategy is activated. That is, we can eliminate a specific edge by adding new vertices, and the following two cases are considered.

Case (2): There are no vertices in  $\mathcal{N}_j^p \cap \mathcal{N}_k^p$  to guarantee positive  $s_{ed}$  , but  $\mathcal{N}_j^p \cap \mathcal{N}_k^p \neq \emptyset$ .

In this case, there are no suitable vertices to ensure that the positive scaling parameter  $s_{ed}$  is available. To complete our edge deletion algorithm, we can eliminate specific edges by adding a new relay vertex. The following assumption describes the criteria for selecting the relay vertices.

<span id="page-5-3"></span>*Assumption 3:* Suppose that the vertices  $v_i \in \mathcal{N}_j^p \cap \mathcal{N}_k^p$  and a relay vertex  $v_r$  meet the following conditions.

- $v_i, v_j, v_k \in \mathcal{N}_r^p$ , and the set  $\{p_i, p_j, p_k, p_r\}$  is in general position;
- If the weight  $\varpi_{jk} = -\Omega_{jk} > 0$ ,  $v_r$  lies in Region a,  $\vartheta$ or  $\mathfrak g$  of a triangle formed by  $v_i$ ,  $v_j$  and  $v_k$ . If the weight  $\overline{\omega}_{jk} = -\Omega_{jk} < 0$ ,  $v_r$  lies in Region b, c, e or f, as shown in Fig. [3.](#page-4-4)

Under Assumption [3,](#page-5-3) we can reconstruct the a framework without edge  $e_{jk}$  as follows. Remove  $e_{jk}$  in the original affine formation framework  $(\mathcal{G}, p)$ , and then add  $v_r$  along with three edges  $e_{ir}$ ,  $e_{ir}$  and  $e_{kr}$  based on Theorem [1.](#page-4-2) Accordingly, a new framework  $(\mathcal{G}_{ed}, \mathbf{p}_{ed})$  is built, where  $\mathcal{G}_{ed}$  =  $(\mathcal{V}\cup \{v_r\}\,,\mathcal{E}\cup \{e_{ir},e_{jr},e_{kr}\}\setminus \{e_{jk}\}),~~\bm{p}_{ed}~=~\left[ \bm{p}^T,\bm{p}_r^T\right]^T.$ The appropriate stress exist and present in [\(19\)](#page-5-4) to guarantee that  $(\mathcal{G}_{ed}, \mathbf{p}_{ed})$  is universally rigid and affinely localizable.

<span id="page-5-4"></span>
$$
\Omega_{ed} = \left[ \begin{array}{c} \mathbf{\Omega}_{end} = \left[ \begin{array}{c} \mathbf{\Omega}_{1 \times n} \\ \hline \mathbf{0}_{1 \times n} \end{array} \right] + \left[ \begin{array}{c} \mathbf{0}_{(n-3)\times(n-3)} \\ \hline \mathbf{0}_{4 \times (n-3)} \end{array} \right] + \frac{\mathbf{0}_{(n-3)\times 4}}{\mathbf{\Omega}_{u}} \cdot \right].
$$
\n(19)

where  $s_{ed} = -\frac{\Omega_{jk}}{\sqrt{2}}$  $\frac{\delta z_{jk}}{\bar{\phi}_2 \bar{\phi}_3}$  and  $\Omega_u = s_{ed} \bar{\phi} \bar{\phi}^T$ . The vector  $\bar{\phi} =$  $\begin{bmatrix} \bar{\phi}_1, & \bar{\phi}_2, & \bar{\phi}_3, & \bar{\phi}_4 \end{bmatrix}^T$  satisfies  $\begin{bmatrix} p_i & p_j & p_k & p_r \\ 1 & 1 & 1 & 1 \end{bmatrix} \vec{\phi} = 0.$ Case (3):  $\mathcal{N}_j^p \cap \mathcal{N}_k^p = \emptyset$ .

In this case, there is no vertex in  $\mathcal{N}_j^p \cap \mathcal{N}_k^p$  such that two relay vertices,  $v_{r_1}$  and  $v_{r_2}$ , are needed with the following assumption.

Assumption 4: Suppose that the vertices  $v_{r_1}$  and  $v_{r_2}$  meet the following conditions.

- Any two vertices of  $v_j$ ,  $v_k$ ,  $v_{r_1}$  and  $v_{r_2}$  can measure their relative positions to each other. The set  $\{p_j, p_k, p_{r_1}, p_{r_2}\}\$ is in general position;
- If the weight  $\overline{\omega}_{jk} = -\Omega_{jk} > 0$ ,  $v_{r_2}$  lies in Region a,  $\mathfrak d$ or  $\mathfrak g$  of a triangle formed by  $v_{r_1}, v_j$  and  $v_k$ . If the weight

<span id="page-6-1"></span><span id="page-6-0"></span>

Fig. 4. An example of edge deletion. (a) An affine formation framework  $(\mathcal{G}, p)$  with  $p = [0, 1, 1, 0, 0, -1, -1, 0, 1, -1]^T$ , where  $e_{23}$  is going to be deleted. (b) An affine formation framework  $(\mathcal{G}, p)$  with  $p = [0, 1, 1, 0, 0, -1, -1, 0]^T$ , where  $e_{23}$  is going to be deleted. (c) The obtained framework  $(\mathcal{G}_{ed}, p_{ed})$  without the edge  $e_{23}$ .

 $\overline{\omega}_{jk} = -\Omega_{jk} < 0$ ,  $v_{r_2}$  lies in Region b, c, e or f, as shown in Fig. [3.](#page-4-4)

Choose  $v_j$  and  $v_k$  to be the neighbors of  $v_{r_1}$ , and add the vertex  $v_{r_1}$  to the original framework  $(\mathcal{G}, p)$  by using Algorithm [1.](#page-4-3) Then, we merge  $v_{r_2}$  to the framework with three edges,  $e_{r_1r_2}$ ,  $e_{jr_2}$  and  $e_{kr_2}$ , based on Theorem [1](#page-4-2) again. We can set the scaling parameter as  $s_{ed} = -\frac{\Omega_{jk}}{\sqrt{1-\lambda}}$  $rac{1}{\phi_2 \phi_3}$ , where  $\left[ \begin{array}{ccc} \bm{p}_{r1} & \bm{p}_{j} & \bm{p}_{k} & \bm{p}_{r2} \ 1 & 1 & 1 & 1 \ \end{array} \right] \left[ \bar{\phi}_1, \ \bar{\phi}_2, \ \bar{\phi}_3, \ \bar{\phi}_4 \right]^T \ = \ \ \ \ \ \ \ \ 0. \ \ \ \ \textrm{Conse-}$ quently, the framework  $(\mathcal{G}_{ed}, \mathbf{p}_{ed})$  is constructed, where  $\mathcal{G}_{ed}$  =  $(\mathcal{V} \cup \{v_{r_1}, v_{r_2}\}, \mathcal{E} \cup \{e_{\sim r_1}, e_{jr_2}, e_{kr_2}, e_{r_1r_2}\} \setminus \{e_{jk}\}), \ \bm{p}_{ed} =$  $\left[ \boldsymbol{p}^T, \boldsymbol{p}_{r_1}^T, \boldsymbol{p}_{r_2}^T \right]^T$ . In Case (3), the vertex  $v_{r_1}$  plays the role

is omitted. To explain our proposed edge deletion strategy more clearly, an example is presented as below.

similar to  $v_i$  in **Case (2)**. Thus, the similar steps and analysis

*Example 1 (Edge Deletion):* To remove  $e_{23}$  in Fig. [4\(a\)](#page-6-0) and [4\(b\),](#page-6-1) two strategies mentioned above are executed, respectively. Suppose that the distance between any two vertices is less than the perception distance  $d_{per}$ . In Fig. [4\(a\),](#page-6-0)  $j = 2$ ,  $k = 3$  so that  $\mathcal{N}_j^p \cap \mathcal{N}_k^p = \{1, 4, 5\}$ . To delete the edge  $e_{23}$ , let  $i = 1$  and  $q = 5$ . We have  $\phi = \frac{1}{\sqrt{10}} [1, -2, -1, 2]^T$  so that  $s_{ed} = -\frac{\Omega_{23}}{1}$  $\frac{\Omega_{23}}{\phi_2 \phi_3} = -\frac{-0.8}{0.2}$  $\frac{0.00}{0.2}$  = 4 > 0. Thus, Corollary [1](#page-6-2) is applied and the obtained affine formation framework is shown in Fig. [4\(c\).](#page-6-3) Nevertheless, in Fig. [4\(b\),](#page-6-1)  $\mathcal{N}_j^p \cap \mathcal{N}_k^p = \{1, 4\} \neq \emptyset$ . If  $i = 1$  and  $q = 4$ , we can calculate  $s_{ed} = -4 < 0$ , which implies that there is no suitable vertices to ensure a positive scaling parameter, indicating that a relay vertex is necessary. Thus, following **Case** (2), choose a relay vertex  $v_5$  with  $p_5 = [1, -1]^T$ , lying in Region  $\mathfrak d$ . Three edges,  $e_{15}$ ,  $e_{25}$ ,  $e_{35}$ , are added to the original framework with  $s_{ed} = 2$ , resulting  $\varpi_{23} = 0$  after the operation. The obtained affine formation framework is also shown in Fig. [4\(c\).](#page-6-3)

<span id="page-6-2"></span>*Corollary 1:* Given a framework  $(\mathcal{G}, p)$  containing an edge  $e_{jk}$  with the weight  $-\Omega_{jk}$ , if there are proper vertices  $v_i$  and  $v_q$ in  $\mathcal{N}_j^p \cap \mathcal{N}_k^p$  to ensure a positive scaling parameter  $s_{ed}$  shown in eq. [\(14\)](#page-5-2), the obtained framework  $(\mathcal{G}_{ed}, p_{ed})$  with the stress matrix [\(18\)](#page-5-5) is universally rigid and affinely localizable.

The proof of Corollary [1](#page-6-2) directly follows a similar sketch with Theorem [1,](#page-4-2) and is omitted here. With the help of Corollary [1,](#page-6-2) we can rearrange the stress to drive the weight of  $e_{jk}$  to zero, which is equivalent to removing the edge from the original framework. The edge deletion strategies proposed

<span id="page-6-4"></span><span id="page-6-3"></span>

<span id="page-6-5"></span>Fig. 5. An example of the removal of a inner node. (a) The inner node  $v_5$  (red, with three children  $v_7, v_8, v_{10}$ ) is removed from the framework, and  $v_7$  is selected to inherit its role. (b) The parent sets of  $v_7, v_8, v_{10}$ are rebuilt, and the hierarchical structure is reconstructed.

in different cases share the same fundamental idea presented in Corollary [1,](#page-6-2) with the differences lying in the selection of neighbor vertices and the design of scaling parameter  $s_{ed}$ .

*Remark 1:* The edge deletion strategy using relay vertices in Case (2) and (3) is directly inspired by Theorem [1.](#page-4-2) To ensure a positive scaling parameter, the position of relay vertex needs to be carefully selected, taking Table [I](#page-5-0) as a reference. In this paper, the relay vertex is assumed to be on standby and respond immediately. In a real robot system, more technical details need to be designed to guarantee the smooth operation of relay robots.

## *C. Vertex Deletion*

In this subsection, we consider an inverse operation of "vertex addition" presented in Section [III-A,](#page-3-7) the removal of a vertex from an affine formation framework  $(\mathcal{G}, \mathbf{p})$ .

Based on Algorithm [1,](#page-4-3) the hierarchical structure of an affine formation framework  $(\mathcal{G}, p)$  is naturally built. Denote the hierarchy of vertices in an original affine formation framework  $(\mathcal{G}_0, \mathbf{p}_0)$  as 0. Define the hierarchy  $h(v_i)$  of a vertex  $v_i$  as the length of its longest path from  $v_i$  to the vertices in  $(\mathcal{G}_0, \mathbf{p}_0)$ . Given a series of free vertices to be integrated into  $(\mathcal{G}_0, \mathbf{p}_0)$ , Algorithm [1](#page-4-3) can be applied to generate  $(\mathcal{G}, p)$ . To add a free  $v<sub>u</sub>$  to the existing graph, three existing vertices are selected to be parents, denoted by  $v_i, v_j, v_k$ . The hierarchy of vertex  $v_u$  is defined as  $h(v_u) = \max(h(v_i), h(v_j), h(v_k)) + 1$ . According to whether a vertex has a child or not, the vertices in the graph can be classified into two categories: (a) *outer node*, a vertex with no child (e.g.,  $v_9$  and  $v_{10}$  in Fig. [5\(a\)\)](#page-6-4); (b) *inner node*, a vertex with at least one child (e.g.,  $v_5$  and  $v_7$  in Fig. [5\(a\)\)](#page-6-4). We consider the vertex deletion problem in both cases in this section.

Case 1 (Deletion of an Outer Node): We first consider the case with an outer node. Consider an affine framework  $(\mathcal{G}, \mathbf{p})$ with  $n \ (n \geq 5)$  vertices, containing an outer node  $v_u$ . After removing vertex  $v_u$  and all edges connected to  $v_u$ , we can obtain a framework  $(\mathcal{G}_{vd}, \mathbf{p}_{vd})$ .

For the affine formation framework  $(\mathcal{G}, p)$ , the stress matrix

can be described as follows.

$$
\boldsymbol{\Omega} = \begin{bmatrix} -\frac{\boldsymbol{\Omega}_{vd}^{B1}}{2d} - \frac{1}{|\cdot|} \frac{\boldsymbol{\Omega}_{vd}^{B2}}{\Omega_{ii}} - \frac{\boldsymbol{\Omega}_{vd}^{B2}}{\Omega_{ij}} - \frac{1}{|\cdot|} \frac{\boldsymbol{\Omega}_{u}^{B2}}{\Omega_{iu}} - \frac{1}{|\cdot|} \frac{\boldsymbol{\Omega}_{u}^{B2}}{\Omega_{iu}} \end{bmatrix} \cdot \begin{bmatrix} \boldsymbol{\Omega}_{vd} & \boldsymbol{\Omega}_{du} \\ \left(\boldsymbol{\Omega}_{vd}^{B2}\right)^{T} & \Omega_{ij} & \Omega_{jj} & \Omega_{jk} \\ -\frac{1}{|\cdot|} \frac{\boldsymbol{\Omega}_{ik}}{\Omega_{iv}} - \frac{1}{|\cdot|} \frac{\boldsymbol{\Omega}_{ik}}{\Omega_{ju}} - \frac{\boldsymbol{\Omega}_{ik}}{\Omega_{ju}} - \frac{\boldsymbol{\Omega}_{ku}}{\Omega_{ku}} - \frac{1}{|\cdot|} \frac{\boldsymbol{\Omega}_{ku}}{\Omega_{uu}} - \end{bmatrix}, \quad (20)
$$

Notably,  $\Omega_{uu} > 0$ . Based on the definition of an equilibrium stress, we have the following equation for  $v_u$ ,

$$
\partial_{iu} (p_i - p_u) + \Omega_{ju} (p_j - p_u) + \Omega_{ku} (p_k - p_u) = 0
$$
  
\n
$$
\Rightarrow \underbrace{\begin{bmatrix} p_i & p_j & p_k & p_u \\ 1 & 1 & 1 & 1 \end{bmatrix}}_{\triangleq P_u} \underbrace{\begin{bmatrix} \Omega_{iu} & \Omega_{ju} & \Omega_{ku} & \Omega_{uu} \end{bmatrix}^T}_{\triangleq \Omega_{\phi}} = 0.
$$
\n(21)

Since  $(\mathcal{G}, p)$  is in general position so that  $v_u$  is not collinear with any two of  $v_i$ ,  $v_j$ ,  $v_k$ , it is deduced that rank  $(P_u)$  = 3 and nullity  $(P_u) = 1$ . Define an auxiliary matrix  $\Omega_{vd}^u$  as below,

$$
\Omega_{vd}^{u} = \frac{1}{\Omega_{uu}} \Omega_{\phi} \Omega_{\phi}^{T} \succeq 0. \tag{22}
$$

Then, we can establish the stress matrix  $\Omega_{vd}$  for the framework  $(\mathcal{G}_{vd}, \mathbf{p}_{vd})$  as below.

$$
\left[\begin{array}{cc} \mathbf{\Omega}_{vd} & \mathbf{0} \\ \mathbf{0} & 0 \end{array}\right] = \mathbf{\Omega} - \left[\begin{array}{cc} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{\Omega}_{vd}^u \end{array}\right],\tag{23}
$$

Thus,

<span id="page-7-0"></span>
$$
\Omega_{vd}=\left[\begin{array}{c} -\frac{\Omega_{y1}^{B1}}{2} \left.\begin{array}{cc} -\frac{\Omega_{y2}^{B2}}{2} \left.\begin{array}{cc} -\frac{\Omega_{y1}^{B2}}{2} \left.\begin{array}{cc} -\frac{\Omega_{y2}^{B2}}{2} \left.\begin{array}{cc} -\frac{\Omega_{y2}^{B2}}{2} \left.\begin{array}{cc} -\frac{\Omega_{y1}^{B2}}{2} \left.\begin{array}{c} -\frac{\Omega_{y1}^{B2}}{2} \left.\begin{
$$

Then, we establish the following theorem to prove  $(\mathcal{G}_{vd}, \mathbf{p}_{vd})$  is universally rigid and affinely localizable.

<span id="page-7-1"></span>*Theorem 2:* Consider an affine framework  $(\mathcal{G}, p)$  with  $n \ (n \geq 5)$  vertices, containing an outer node  $v_u$ . After removing vertex  $v_u$  and all edges connected to  $v_u$ , we can obtain a universally rigid and affinely localizable framework  $(\mathcal{G}_{vd}, \mathbf{p}_{vd})$  with a stress matrix  $\mathbf{\Omega}_{vd}$  shown in [\(24\)](#page-7-0), where  $\mathcal{G}_{vd} = (\mathcal{V} \setminus \{v_u\}, \mathcal{E} \setminus \{e_{iu}, e_{ju}, e_{ku}\}).$ 

*Proof:* It is obvious that  $(\mathcal{G}_{vd}, \mathbf{p}_{vd})$  is in general position. Then, we need to clarify that  $\Omega_{vd} \succeq 0$ , rank  $(\Omega_{vd}) = n-4$  and the block matrix describing the stress among followers  $\Omega_{ff}^{vd} \succ$ 0. The following proof has a similar sketch with Theorem [1](#page-4-2) in Appendix [I.](#page-10-1) Based on the characteristics of  $\Omega_{\nu d}$ , we conclude that  $(\mathcal{G}_{vd}, \mathbf{p}_{vd})$  is universally rigid and affinely localizable.

By directly applying Theorem [2,](#page-7-1) we can remove outer nodes without damaging the universal rigidity and affine localizability of the remaining framework.

Case 2 (Deletion of an Inner Node): When an inner node leaves the framework (e.g.,  $v_5$  in Fig. [5\(a\)\)](#page-6-4), the universal rigidity and affine localizability of the framework are destroyed and need to be repaired. Hence, a strategy inspired by inheritance is derived.

<span id="page-7-2"></span>*Assumption 5:* For an inner node  $v_u$ , denote the parents as  $\mathcal{P}_u = \{v_{p_i}^u, v_{p_i}^u, v_{p_k}^u\}$  and the children as  $\mathcal{C}_u$  =  $\{v_{c_1}^u, v_{c_2}^u \cdots v_{c_m}^u\}$ , where  $h(v_{c_1}^u) \leq \cdots \leq h(v_{c_m}^u)$ . Suppose that the perception distance is large enough to ensure  $v_{\mathcal{P}} \in$ 

 $\mathcal{N}_{\mathcal{C}}^p$ , where  $v_{\mathcal{P}} \in \mathcal{P}_u$  and  $v_{\mathcal{C}} \in \mathcal{C}_u$ . The set  $\{p_{\mathcal{P}}\} \cup \{p_{\mathcal{C}}\}$  is in general position, where  $p_{\mathcal{P}}$  is the position of  $v_{\mathcal{P}}$ , and  $p_{\mathcal{C}}$  is defined analogously.

Assumption [5](#page-7-2) lays the foundation for establishing edges between the parents and children of  $v_u$ . Based on Theorem [1,](#page-4-2) a matrix  $\Omega_b$  in [\(9\)](#page-4-1) is constructed to update the stress matrix when adding a free vertex. Accordingly, denote the auxiliary matrix to add  $v_u$ ,  $v_{c_1}^u \cdots v_{c_m}^u$  as  $\Omega_b^u$ ,  $\Omega_b^{uc_1} \cdots \Omega_b^{uc_m} \in \mathbb{R}^{n \times n}$ , and their orders are unified by inserting zeros. The steps of removing an inner node  $v_u$  is presented as follows.

- S1. Remove all edges connecting  $v_u$ , and update the stress matrix as  $\boldsymbol{\Omega}_{cache}~=~\boldsymbol{\Omega} - \bar{\boldsymbol{\Omega}}_b^u - \bar{\boldsymbol{\Omega}}_b^{uc_1} - \cdots - \bar{\boldsymbol{\Omega}}_b^{uc_m}.$ Obviously, the elements in the  $u$ -th row and  $u$ -th column of  $\Omega_{cache}$  become zero. Delete the u-th row and the u-th column, and a simplified matrix is shown as  $\tilde{\Omega}_{cache} \in$  $\mathbb{R}^{(n-1)\times(n-1)}$ .
- S2. The vertex  $v_{c_1}$ , a child of  $v_u$  that has the highest hierarchy, is chosen to inherit its role in the framework. Choose one vertex from  $\mathcal{P}_u \backslash \mathcal{P}_{c_1}$ , labeled by  $v_{p_1}^{c_1}$ . Rebuild the parent set of  $v_{c_1}$ ,  $\bar{\mathcal{P}}_{c_1}$ , with  $v_{p_1}^{c_1}$  and the remaining vertices in  $\mathcal{P}_{c_1}$ . Using the positions of  $v_{c_1}$  and its parents, construct the auxiliary matrix  $\mathbf{\Omega}_b^{c_1} \in \mathbb{R}^{(n-1)\times (n-1)}$ ;
- S3. Rebuild the parent sets of other vertices in  $\mathcal{C}_u \setminus \{v_{c_1}\}.$ Taking the vertex  $v_{c_2}$  as an example, if  $v_{c_1}$  is not a parent of  $v_{c_2}$  (i.e.,  $\mathcal{P}_{c_2} = \{v_u, v_{p_i}^{c_2}, v_{p_k}^{c_2}\}\)$ , the new parent set is  $\bar{P}_{c_2} = \{v_{c_1}, v_{p_i}^{c_2}, v_{p_k}^{c_2}\}$ , where  $v_u$  is replaced by  $v_{c_1}$ . If  $v_{c_1} \in \mathcal{P}_{c_2}$ , we can choose one vertex in  $\mathcal{P}_u \setminus \mathcal{P}_{c_2}$  to replace  $v_u$ , e.g.,  $\bar{\mathcal{P}}_{c_2} = \{v_{p_i}^u, v_{c_1}, v_{p_k}^{c_2}\}$ . The remaining children of  $v<sub>u</sub>$  follow the strategy. An example is presented in Fig. [5\(b\).](#page-6-5)
- S4. Construct auxiliary matrices for vertices in  $\mathcal{C}_u$  ${v_{c_1}}$  using their own and parental positions, i.e.,  $\Omega_b^{c_1c_2}, \cdots, \Omega_b^{c_1c_m} \in \mathbb{R}^{(n-1)\times (n-1)}$  (the order is unified by inserting zero). Accordingly, a new affine formation framework  $(\mathcal{G}_{vd}, \mathbf{p}_{vd})$  is reconstructed without  $v_u$ , and the corresponding stress matrix is

<span id="page-7-3"></span>
$$
\Omega_{vd} = \tilde{\Omega}_{cache} + \Omega_b^{c_1 c_2} + \dots + \Omega_b^{c_1 c_m}.
$$
 (25)

The universal rigidity and affine localizability of  $(\mathcal{G}_{vd}, \mathbf{p}_{vd})$ can be proved by analyzing the characteristic of  $\Omega_{vd}$  shown in Eq. [\(25\)](#page-7-3). Combining the proof sketch of Theorem [1](#page-4-2) and [2,](#page-7-1) a similar process can be implemented, which is omitted here. To explain our method more clearly, an example is presented.

*Example 2 (Vertex Deletion):* Using *Algo*rithm [1,](#page-4-3) an affine formation framework shown in Fig.  $6(a)$  is generated, where  $p$  $[8, 0, 0, 8, -8, 0, 0, -8, 9, -10, 0, -12, 11, 1, 14, -14, -7, -5]^T$  $v_7$ ,  $v_8$ ,  $v_9$  are outer nodes and  $v_5$ ,  $v_6$  are inner nodes. To remove an outer node (e.g.,  $v_9$ ), Theorem [2](#page-7-1) is directly applied. After calculating, the eigenvalues of the stress matrix are 0, 0, 0, 0.107, 0.398, 0.91, 1.82, 4.77, which demonstrates the universal rigidity and affine localizability of the obtained framework without  $v_9$ , as shown in Fig. [6\(b\).](#page-8-3) To verify the strategy of deleting an inner node, take the removal of  $v_5$ as an example. After removing all edges connected to  $v_5$ , the graph is shown in Fig. [6\(c\).](#page-8-4) Obviously, the rigidity of framework is destroyed. To repair the universal rigidity and affine localizability, the second and third step, S2 and S3, are

<span id="page-8-3"></span><span id="page-8-2"></span>

<span id="page-8-6"></span><span id="page-8-5"></span><span id="page-8-4"></span>Fig. 6. An example of the vertex deletion algorithm. (a) The original affine formation framework, where  $v_1, v_2, v_3 \in \mathcal{V}_l$ . (b) The removal of an outer node  $v_9$ . (c) The removal of an inner node  $v_5$ . S1-S2: delete all edges connected to  $v_5$ , and  $v_6$  is chosen to inherit of the role of  $v_5$ . (c) The removal of an inner node  $v_5$ . S3-S4: repair the universal rigidity and affine localizability.

executed. We choose  $v_6$  to inherit the role of  $v_5$ , so that the hierarchical relationship between vertices is reconstructed, as presented in Tab. [2.](#page-8-5) The final framework is shown in Fig. [6\(d\),](#page-8-6) and the eigenvalues of the corresponding stress matrix obtained from [\(25\)](#page-7-3) are 0, 0, 0, 0.204, 0.36, 1.19, 1.38, 4.87. In a word, the effectiveness of our proposed approached in reconstructing a universally rigid and affinely localizable framework has been validated.

The proposed vertex deletion strategy is also distributed, as it only utilizes local measurements to change the local structure of the affine framework. Taking the deletion of a inner node shown in Fig. [6\(c\)](#page-8-4) and [6\(d\)](#page-8-6) as an example, the connections among the inner node's parents and children are reconstructed, and the remaining part in the framework is preserved. The affine formation framework generated by Algorithm [1](#page-4-3) has a clear hierarchical structure with specific parents and children, making it convenient for further research. For any other affine formation framework, as long as a similar hierarchical structure can be established, our proposed vertex deletion strategy can be extended.

### IV. DISCUSSION

#### <span id="page-8-0"></span>*A. Extension to three-dimensional space*

The strategies proposed in Section [III](#page-3-0) concentrate on the affine formation framework construction in  $\mathbb{R}^2$ . Actually, our method can be extended to three-dimensional scenarios following the same idea. Taking the vertex addition strategy as an example, a new vertex  $v_u$  is intended to be added to  $(\mathcal{G}, p)$  in three-dimensional space. Inspired by Theorem [1,](#page-4-2) four edges are introduced to the original framework  $(\mathcal{G}, \mathbf{p})$ , and the corresponding stress are determined by the position of the new vertex  $v<sub>u</sub>$  with respect to the four affinely independent vertices in  $\mathcal{N}_u^p$ , denoted by  $v_i$ ,  $v_j$ ,  $v_k$  and  $v_g$ . Similar to Section [III-](#page-3-7)[A,](#page-3-7) suppose that the set  $\{p_i, p_j, p_k, p_g, p_u\}$  is in general position.

To grow the affine framework with a new vertex  $v<sub>u</sub>$ , four edges  $e_{iu}$ ,  $e_{ju}$ ,  $e_{ku}$ ,  $e_{gu}$  are linked to  $(\mathcal{G}, \mathbf{p})$  to obtain a extended framework  $(\mathcal{G}^+, p^+)$ , where  $p^+ = \left[p^T, p_u^T\right]^T$  and  $\mathcal{G}^+ = (\mathcal{V} \cup \{v_u\}, \mathcal{E} \cup \{e_{iu}, e_{ju}, e_{ku}, e_{gu}\})$ . For the new vertex  $v_u$ , we have the following equation due to the definition of the equilibrium stress,

$$
\varpi_{iu} (p_i - p_u) + \varpi_{ju} (p_j - p_u) + \varpi_{ku} (p_k - p_u) + \varpi_{gu} (p_g - p_u) = 0,
$$
\n(26)

where  $\varpi_{iu}$ ,  $\varpi_{ju}$ ,  $\varpi_{ku}$  and  $\varpi_{gu}$  are the weights of edges  $\lceil$  $e_{iu}, e_{ju}, e_{ku}, e_{gu}$ . Define  $P_u$  as  $P_u \triangleq$  $\begin{bmatrix} p_i & p_j & p_k & p_g & p_u \ 1 & 1 & 1 & 1 & 1 \end{bmatrix}$ . Since rank $(P_u) = 4$ , there is a nonzero vector  $\boldsymbol{\phi} = [\phi_1, \phi_2, \phi_3, \phi_4, \phi_5]^T$  satisfying  $\boldsymbol{P}_u \boldsymbol{\phi} = \mathbf{0}$ . Similarly, define  $\Omega_u = s\phi\phi^T$ , where  $s > 0$  is the scaling parameter. Accordingly, the weights can be represented by  $\overline{\omega}_{iu} = -s\phi_1\phi_5$ ,  $\overline{\omega}_{ju} = -s\phi_2\phi_5$ ,  $\overline{\omega}_{ku} = -s\phi_3\phi_5$  and  $\varpi_{gu} = -s\phi_4\phi_5$ . The augmented stress matrix  $\Omega^+$  can be rewritten as

<span id="page-8-7"></span>
$$
\Omega^{+} = \left[ \begin{array}{cc} \Omega & 0_{n \times 1} \\ \overline{0}_{1 \times n} & 0 \end{array} \right] + \left[ \begin{array}{c} \mathbf{0}_{(n-4)\times (n-4)} & \mathbf{0}_{(n-4)\times 5} \\ \overline{0}_{5 \times (n-4)} & \end{array} \right]. \tag{27}
$$

Correspondingly, we have the following result on vertex addition in  $\mathbb{R}^3$ .

<span id="page-8-8"></span>*Corollary 2:* Under Assumption [1,](#page-2-2) for a given affine formation framework  $(\mathcal{G}, p)$  in  $\mathbb{R}^3$ , adding a new vertex  $v_u$  and four edges between  $v_u$  with four vertices  $v_i, v_j, v_k$  and  $v_g$ , the universal rigidity and affine localizability are inherited by the extended affine formation framework  $(\mathcal{G}^+, p^+)$  with a stress matrix  $\Omega^+$  described in eq. [\(27\)](#page-8-7).

The similar scheme employed in the proof of Theorem [1](#page-4-2) can be applied to explain Corollary [2,](#page-8-8) which is omitted here for simplicity. Inspired by Corollary [2,](#page-8-8) the strategies for edge and vertex deletion in  $\mathbb{R}^3$  can be extended along the lines of their counterparts in two-dimensional space.

#### *B. Complexity Analysis*

It is evident that our proposed framework reconstruction strategies are incremental, inherently possessing a relatively low time complexity. When the topology of the formation changes, we need a little computational resources to reconstruct the new framework, because only low dimensional matrix calculations are required in our algorithm. Taking Algorithm [1](#page-4-3) as an example, providing that there are  $q$  new vertices joining the formation, the time complexity can be calculated as  $O(qn)$ . Note that we can simultaneously apply Algorithm [1](#page-4-3) to all new vertices if the vertex addition process happens in parallel. Then, the time complexity will be further reduced to  $O(n)$ . Therefore, in practice, our algorithm is portable enough to be applied to robots with limited computing power to deal with a variety of collaborative tasks in time.

#### V. SIMULATIONS

<span id="page-8-1"></span>In this section, two simulations and a comparison are carried out to validate our proposed algorithms.

Vertex	<b>Before Operation</b>			After Operation			
	Hierarchy $(h(\cdot))$	Parents	Children	Hierarchy $(h(\cdot))$	Parents	Children

## *A. Simulation 1: Growing Framework for Affine Formations*

By using Algorithm [1,](#page-4-3) we present simulations to grow an eligible affine formation framework with different number of agents, as shown in Fig. [7.](#page-9-1) An original framework with four vertices is given in Fig. [7\(a\),](#page-9-2) then a series of vertices with random positions are considered to be added to the framework. As described in Fig. [7\(b\)](#page-9-3)[-7\(d\),](#page-9-4) frameworks with different swarm size are generated while maintaining universal rigidity and affine localizability, which implying the effectiveness of the proposed distributed vertex addition strategy. We further demonstrate the rigidity of constructing affine frameworks by comparative simulations with [11], where a MISDP problem is established and an optimization-based topology design scheme is designed. We use two methods to grow affine formation frameworks with the same number of agents. The programs run on a laptop with AMD Ryzen 7 and 16 GB memory. Each simulation is repeated ten times and the average runtime is recorded in Table. [III.](#page-9-5) It is obvious that Xiao's method takes much more time than ours, due to the fact that the number of variables that need to be optimized in the MISDP algorithm increases rapidly with the number of vertices, resulting in a sharp increase in runtime. As a comparison, our method only focuses on several neighbors near the newly added vertex, bringing about a significant reduction in computational cost, which reveals the potential of our method in onboard applications in robot swarms.

<span id="page-9-3"></span><span id="page-9-2"></span>

<span id="page-9-4"></span><span id="page-9-1"></span>Fig. 7. An example to grow affine formation frameworks using Algorithm [1.](#page-4-3) (a) The original framework with 4 agents. (b) The obtained framework after adding 50 agents. (c) The framework after adding after adding 100 agents. (d) The framework after adding after adding 200 agents.

## *B. Simulation 2: Edge Deletion & Vertex Addition and Deletion*

In this subsection, a scenario is designed to validate the effectiveness of our proposed agent-level framework construction algorithms, namely the proposed vertex addition, edge deletion and vertex deletion strategies in section [III.](#page-3-0) We couple the affine formation framework construction strategies with the formation tracking control law proposed in [5], with the former providing the nominal framework for the latter. In the scenario, we consider a group of fixed-wing unmanned aerial vehicles (UAVs) modeled by unicycles moving in two-dimensional space while tracking moving leaders and achieving affine transformations. The convergence of affine formation tracking errors can serve as a powerful evidence to prove the effectiveness of our framework construction algorithms. Moreover, the adopted control scheme [5] is just an example and can be replaced by other similar affine formation control laws.

<span id="page-9-0"></span>We consider a group of six agents with an original framework shown in Fig. [8\(a\),](#page-10-2) where the first three red vertices are regarded as leaders. Followers are driven to track leaders while achieving affine transformations. During the maneuver, agents adjust the topological connection between each other, as shown

<span id="page-10-3"></span><span id="page-10-2"></span>

<span id="page-10-5"></span><span id="page-10-4"></span>Fig. 8. An example of edge deletion, vertex addition and deletion. (a) The original framework. (b) The obtained framework after deleting  $e_{23}$ and  $e_{46}$ . (c) The framework after adding two vertices, denoted by  $v_7$ and  $v_8$ . (d) The topology after three vertices deletion.

<span id="page-10-6"></span>Fig. 9. The trajectory of fixed-wing UAVs.

in Fig. [8\(b\).](#page-10-3) Then, two additional agents join the formation (Fig. [8\(c\)\)](#page-10-4) following Algorithm [1.](#page-4-3) After a period of formation flight, three agents leave the formation to perform other tasks, and the framework is reshaped as shown in Fig. [8\(d\).](#page-10-5) Fig. [9](#page-10-6) depicts the trajectory of UAVs and Fig. [10](#page-10-7) shows the evolution of formation tracking errors  $\|\boldsymbol{p}_i - \boldsymbol{p}_i^*\|$ , where  $\boldsymbol{p}_i$  represents the position of the *i*-th UAV and  $p_i^*$  represents the desired one. It can be seen that the target formations can be achieved while time-varying affine transformations are performed to pass through various environments, implying that the obtained framework is universally rigid and affine localizable.

Based on the simulation results, it is evident that our proposed distributed framework construction algorithms are highly effective to generate and reconstruct affine formation frameworks, demonstrating the potential for extensive applications in robot swarms.

## VI. CONCLUSION

<span id="page-10-0"></span>This paper have addressed the issue of constructing affine formation frameworks in a distributed manner in three scenarios, i.e., vertex addition, edge deletion and vertex deletion.

<span id="page-10-7"></span>Fig. 10. The evolution of formation tracking errors for fixed-wing UAVs in Scenario 1.

We have designed strategies to construct frameworks with universal rigidity and affine localizability from the geometric perspective based on the structure of weighted graphs used to describe topology of affine formations. Naturally, comprehensive theoretical analysis has been provided to demonstrate the effectiveness, and simulations have been presented to verify the compatibility with distributed affine formation control proposals. Moreover, the comparative simulation has demonstrated the rapidity in constructing large-scale affine formations. Our approach relaxes the requirements for global information and computing resources, making it more easy to implement for robot swarms to perform various tasks. One future research direction is to extend distributed framework construction algorithms to directed graphs.

## <span id="page-10-1"></span>APPENDIX I THE PROOF OF THEOREM [1](#page-4-2)

To complete the proof of Theorem [1,](#page-4-2) the following lemmas are introduced for the analysis presented in the sequel.

<span id="page-10-8"></span>*Lemma 4:* [17] Given PSD matrices  $X \in \mathbb{R}^{n \times n}$  and  $Y \in$  $\mathbb{R}^{n \times n}$ , let  $\mathbf{Z} = \mathbf{X} + \mathbf{Y}$ . Then for any nonzero vector  $\boldsymbol{\varepsilon} \in \mathbb{R}^n$ ,  $\varepsilon \in \text{null}(\mathbf{Z})$  if and only if  $\varepsilon \in \text{null}(\mathbf{X})$  and  $\varepsilon \in \text{null}(\mathbf{Y})$ .

<span id="page-10-9"></span>*Lemma 5 (Rank-Nullity Theorem [29]):* If there is a matrix A with x rows and y columns over a field, then rank(A) + nullity(A) = y, where nullity(A) means the nullity of the matrix A, that is, the dimension of the kernel of A.

<span id="page-10-10"></span>*Lemma 6 ( [30]):* For any symmetric matrix  $M$  of the form

$$
M = \left[ \begin{array}{cc} A & B \\ B^T & C \end{array} \right],\tag{28}
$$

if  $C$  is invertible then the following properties hold:

(1)  $M \succ 0 \Longleftrightarrow C \succ 0$  and  $A - BC^{-1}B^{T} \succ 0$ .

(2) If  $C \succ 0$ , then  $M \succeq 0 \Longleftrightarrow A - BC^{-1}B^{T} \succ 0$ .

Then, let us complete the proof of Theorem [1.](#page-4-2)

*Proof:* Fist of all, with a positive s, we can prove that  $\overline{\omega}_{uu} = s\phi_4^2$  in Eq. [\(8\)](#page-4-0) is positive. Specifically, it is equivalent to prove  $\phi_4 \neq 0$  because of  $s > 0$ . Suppose  $\phi_4 = 0$ , we get the following equations based on eq.[\(7\)](#page-3-8),

$$
\phi_1 + \phi_2 + \phi_3 = 0
$$
,  $\phi_1 (\mathbf{p}_i - \mathbf{p}_k) + \phi_2 (\mathbf{p}_j - \mathbf{p}_k) = \mathbf{0}$ . (29)

Since  $(\mathcal{G}, p)$  is in general position, three vertices  $v_i$ ,  $v_j$ ,  $v_k$ are non-collinear. The vectors  $(p_i - p_k)$  and  $(p_j - p_k)$  are linearly independent, implying  $\phi_1 = \phi_2 = 0$ . Then,  $\phi_3 = 0$ holds. Consequently,  $\phi = 0$  is obtained, which contradicts with the fact that  $\phi$  is a nonzero vector. Therefore, we have  $\phi_4 \neq 0$  so that  $\varpi_{uu}$  is positive when  $s > 0$ .

Then, in the newly obtained framework  $(\mathcal{G}^+, p^+)$ , we have  $\mathcal{V}_l^+ = \mathcal{V}_l, \ \mathcal{V}_f^+ := \mathcal{V}_f \cup \{v_u\} \ \text{ and } \ \mathbf{\Omega}^+ := \begin{bmatrix} \mathbf{\Omega}_{ll}^+ & \mathbf{\Omega}_{lf}^+ \\ \mathbf{\Omega}_{fl}^+ & \mathbf{\Omega}_{ff}^+ \end{bmatrix}.$ Combining Lemmas [1](#page-1-1) and [3,](#page-2-0) to demonstrate  $(G^+, p^+)$  is universally rigid and affinely localizable, it is equivalent to prove the following conditions: (1)  $\Omega^+$  is PSD; (2) rank  $(\Omega^+)$  =  $n-2$ ; (3) the block matrix  $\mathbf{\Omega}_{ff}^+$  is positive definite. These are proven one by one as follows.

- (1) Based on Assumption [1](#page-2-2) and eq. [\(8\)](#page-4-0), we have  $\Omega$  and  $\Omega_u$ are both PSD, it is obvious that  $\Omega_a$  and  $\Omega_b$  in [\(9\)](#page-4-1) are both PSD. Then according to Lemma [4,](#page-10-8) the matrix  $\Omega^+$ is PSD naturally.
- (2) Then, we analyze the rank of  $\Omega^+$ . According to Lemma [5,](#page-10-9) Let us start with the kernel of  $\Omega^+$ . Based on Lemma [2,](#page-1-2) we obtain the null space of  $\Omega_a$  in eq. [\(9\)](#page-4-1) is

$$
\mathbb{S}_{a} = \text{span}\left(\left[\begin{array}{c} \mathbf{p}_{1,1} \\ \vdots \\ \mathbf{p}_{i,1} \\ \mathbf{p}_{j,1} \\ \mathbf{p}_{k,1} \\ \mathbf{q}_{u,1} \end{array}\right], \left[\begin{array}{c} \mathbf{p}_{1,2} \\ \vdots \\ \mathbf{p}_{i,2} \\ \mathbf{p}_{j,2} \\ \mathbf{p}_{k,2} \\ \mathbf{q}_{u,2} \end{array}\right], \left[\begin{array}{c} 1 \\ \vdots \\ 1 \\ 1 \\ \vdots \\ 1 \\ c_{u} \end{array}\right] \right) (30)
$$
\n
$$
\triangleq \text{span}\left(\mathbf{n}_{1}^{a}, \mathbf{n}_{2}^{a}, \mathbf{n}_{3}^{a}\right),
$$

where  $p_{i,1}$  is the first component of  $p_i$  ( $i \in \{1, \dots, n\}$ ), and  $p_{i,2}$  is defined analogously.  $q_{u,\sim}$  and  $c_u$  are any arbitrary scalars. Similarly, the null space of  $\Omega_b$  is

$$
\mathbb{S}_{b} = \text{span}\left(\left[\begin{array}{c} q_{1,1} \\ \vdots \\ q_{(i-1)\cdot 1} \\ p_{i,1} \\ p_{j,1} \\ p_{u,1} \\ p_{u,1} \end{array}\right], \left[\begin{array}{c} q_{1,2} \\ \vdots \\ q_{(i-1)\cdot 2} \\ p_{i,2} \\ p_{i,2} \\ p_{u,2} \end{array}\right], \left[\begin{array}{c} c_{1} \\ \vdots \\ c_{i} \\ 1 \\ 1 \\ 1 \\ 1 \end{array}\right]\right)
$$

$$
\triangleq \text{span}\left(\mathbf{n}_{1}^{b}, \mathbf{n}_{2}^{b}, \mathbf{n}_{3}^{b}\right),\tag{31}
$$

According to Lemma [4](#page-10-8) and eq. [\(9\)](#page-4-1), the null space of  $\Omega^+$ can be presented as null  $(\Omega^+) = \mathbb{S}_a \cap \mathbb{S}_b$ , whose nominal form is shown as

$$
\alpha_1 \mathbf{n}_1^a + \alpha_2 \mathbf{n}_2^a + \alpha_3 \mathbf{n}_3^a = \beta_1 \mathbf{n}_1^b + \beta_2 \mathbf{n}_2^b + \beta_3 \mathbf{n}_3^b, \quad (32)
$$

where  $\alpha_i$  and  $\beta_i$  (i = 1, 2, 3) are scalars that are not all zero. Because  $\mathbb{S}_a$  and  $\mathbb{S}_b$  share three identical elements, the following equation is deduced,

$$
(\alpha_1 - \beta_1) \begin{bmatrix} p_{i,1} \\ p_{j,1} \\ p_{k,1} \end{bmatrix} + (\alpha_2 - \beta_2) \begin{bmatrix} p_{i,2} \\ p_{j,2} \\ p_{k,2} \end{bmatrix} + (\alpha_3 - \beta_3) \begin{bmatrix} 1 \\ 1 \\ 1 \\ 33 \end{bmatrix} = \mathbf{0},
$$

which means

$$
\underbrace{\left[\begin{array}{cc} p_i & p_j & p_k \\ 1 & 1 & 1 \end{array}\right]}_{\triangleq P_k} \left[\begin{array}{c} \alpha_1 - \beta_1 \\ \alpha_2 - \beta_2 \\ \alpha_3 - \beta_3 \end{array}\right] = 0. \tag{34}
$$

Because vertices  $v_i$ ,  $v_j$  and  $v_k$  are not collinear, rank  $(P_k)$  = 3 holds. Accordingly, we have  $\alpha_i$  =

 $\beta_i, \forall i \in \{1, 2, 3\}.$  Assume there is a vector  $\mathbf{v} \in$ null  $(\Omega^+)$ , then we will show that v can be represented by  $p_{i,1}^+, p_{i,2}^+$   $(i \in \{1, \cdots, n+1\})$  and  $\mathbf{1}_{n+1}$ . According to Lemma [4,](#page-10-8)  $v \in \text{null}(\Omega^+)$  implies  $v \in \mathbb{S}_a$  and  $v \in \mathbb{S}_b$ . That is,

$$
\boldsymbol{v}=\alpha_1\boldsymbol{n}_1^a+\alpha_2\boldsymbol{n}_2^a+\alpha_3\boldsymbol{n}_3^a=\alpha_1\boldsymbol{n}_1^b+\alpha_2\boldsymbol{n}_2^b+\alpha_3\boldsymbol{n}_3^b
$$

Thus, let the last entry in  $n_i^a$  equal the last entry in  $n_i^b$ , and the first *n* entries in  $n_i^b$  equal the first *n* entries in  $n_i^a$ . It follows that

$$
\mathbf{v} = \alpha_1 \begin{bmatrix} \mathbf{p}_{1,1} \\ \vdots \\ \mathbf{p}_{i,1} \\ \mathbf{p}_{j,1} \\ \mathbf{p}_{k,1} \\ \mathbf{p}_{u,1} \end{bmatrix} + \alpha_2 \begin{bmatrix} \mathbf{p}_{1,2} \\ \vdots \\ \mathbf{p}_{i,2} \\ \mathbf{p}_{j,2} \\ \mathbf{p}_{u,2} \end{bmatrix} + \alpha_3 \begin{bmatrix} 1 \\ \vdots \\ 1 \\ 1 \\ 1 \end{bmatrix}
$$
(35)

which means

$$
\operatorname{null}\left(\Omega^{+}\right)=\operatorname{col}\left(\underbrace{\left[\begin{array}{cccc}p_{1} & \cdots & p_{i} & p_{j} & p_{k} & p_{u} \\ 1 & \cdots & 1 & 1 & 1 & 1\end{array}\right]^{T}}_{\triangleq \bar{P}(p^{+})}\right).
$$

Since rank  $(\bar{P}(p^+)) = 3$ , we have nullity  $(\Omega^+) = 3$ so that rank  $(\Omega^+) = n + 1 - 3 = n - 2$ . According to Lemma [1,](#page-1-1) the framework  $(\mathcal{G}^+, p^+)$  is universally rigid.

- (3) Now consider the block matrix  $\Omega_{ff}^+$ . The added vertex  $v_u$ plays the role of a follower in  $(\check{\mathcal{G}}^+, p^+)$ . Depending on whether the selected the vertices  $v_i$ ,  $v_j$  and  $v_k$  represent leaders or not, there are four situations in total as below.
	- All the vertices  $v_i, v_j, v_k \in V_l$ . Based on Assumption [1,](#page-2-2) we get the block stress matrix  $\Omega_{ff}$  associated with  $\Omega$  is positive definite. If  $v_i$ ,  $v_j$ ,  $v_k \in V_l$ , then  $\Omega_{ff}^+$  can be described by  $\Omega^+_{ff} = \left[ -\frac{\Omega_{ff}}{\Omega_{1\times n_f}} - \frac{\Omega_{n_f\times 1}}{\varpi_{uu}} \right]$ . Since  $\varpi_{uu} > 0$  when  $s > 0$ ,  $\Omega_{ff}^+$   $> 0$  holds naturally.
	- Two of the vertices  $v_i$ ,  $v_j$ ,  $v_k$  belong to  $\mathcal{V}_l$ , and one belongs to  $V_f$ .

Without losing generality, assume  $v_i \in V_f$  and  $\lceil$  $v_j, v_k \in V_l$  so that  $\Omega_{ff}$  can be divided into  $\Omega_{ff} =$  $\overline{1}$  $\mathbf{\Omega}_{ff}^{P1}$  ;  $\mathbf{\Omega}_{ff}^{P2}$  $\left(\mathbf{\Omega}_{ff}^{P2}\right)^{T-1}$ 1  $\geq 0$ . Based on Lemma [6,](#page-10-10) we

have  $\Omega_{ii} > 0$  and  $\Omega_{ff}^{P1} - \frac{1}{\Omega_{ii}}$  $\frac{1}{\Omega_{ii}}{\bm{\Omega}}^{P2}_{ff}\left({\bm{\Omega}}^{P2}_{ff}\right)^T \succ 0.$ After adding a new vertex  $v_u$ , based on eq. [\(9\)](#page-4-1), the block stress matrix  $\Omega_{ff}^+$  associated with the augmented framework  $(G^+, p^+)$  is described as follows.

<span id="page-11-0"></span>
$$
\Omega_{ff}^{+} = \begin{bmatrix} \Omega_{ff}^{P1} & \Omega_{ff}^{P2} & \mathbf{0}_{\{n_f-1\}\times 1} \\ \left(\Omega_{ff}^{P2}\right)^{T} & \Omega_{ii} + \frac{\varpi_{iu}^{T}}{\varpi_{uu}} & -\varpi_{iu} \\ \mathbf{0}_{1\times(n_f-1)} & -\varpi_{iu} & \varpi_{uu} \end{bmatrix} . \tag{36}
$$

Based on Lemma [6,](#page-10-10) we have

$$
\left[\begin{array}{cc} \Omega_{ii} + \frac{\varpi_{iu}^2}{\varpi_{uu}} & -\varpi_{iu} \\ -\varpi_{iu} & \varpi_{uu} \end{array}\right] \succ 0.
$$

Hence, the following equation is deduced.

$$
\Omega_{ff}^{P1} - \left[ \begin{array}{cc} \mathbf{\Omega}_{ff}^{P2} & \mathbf{0}_{(n_f-1)\times 1} \end{array} \right] \cdot \left[ \begin{array}{c} \Omega_{ff} & \mathbf{\Omega}_{iu} + \frac{\varpi_{iu}^2}{\varpi_{uu}} & -\varpi_{iu} \\ -\varpi_{iu} & \varpi_{uu} \end{array} \right]^{-1} \left[ \begin{array}{c} \left( \mathbf{\Omega}_{ff}^{P2} \right)^T \\ \mathbf{0}_{1 \times (n_f-1)} \end{array} \right] (37)
$$

$$
= \mathbf{\Omega}_{ff}^{P1} - \frac{1}{\Omega_{ii}} \mathbf{\Omega}_{ff}^{P2} \left( \mathbf{\Omega}_{ff}^{P2} \right)^T \succ 0.
$$

Thus,  $\Omega_{ff}^+$  in [\(36\)](#page-11-0) is positive definite.

• Two of the vertices  $v_i$ ,  $v_j$ ,  $v_k$  belong to  $\mathcal{V}_f$ , and one belongs to  $V_l$ .

In this situation, we apply Lemma [6](#page-10-10) repeatedly in a similar way to prove that the symmetric matrix  $\Omega_{ff}^+$  is positive definite. Without losing its generality, assume  $v_i$ ,  $v_j \in V_f$  and  $v_k \in V_l$ , and  $\Omega_{ff}$  can be presented as  $\Omega_{ff} =$  $\lceil$  $\overline{1}$  $\Omega_{ff}^{P1}$  ,  $\Omega_{ff}^{P2}$  $\overline{\left( \Omega_{ff}^{P2} \right)^{T}} + \overline{\frac{\Omega_{ii}}{\Omega_{ij}}} \cdot \overline{\frac{\Omega_{ij}}{\Omega_{jj}}}$ 1  $\vert \cdot$ Obviously, due to  $\Omega_{ff} \rightarrow 0$ , we have  $\left[\begin{array}{cc} \Omega_{ii} & \Omega_{ij} \\ \Omega_{ij} & \Omega_{jj} \end{array}\right] \succ 0$  and  $\Omega_{ff}^{P1} - \Omega_{ff}^{P2} \left[ \begin{array}{cc} \Omega_{ii} & \Omega_{ij} \ \Omega_{ij} & \Omega_{jj} \end{array} \right]^{-1} \left( \Omega_{ff}^{P2} \right)^{T} \succ 0.$  (38)

<span id="page-12-1"></span>
$$
\Omega_{ff}^2 - \Omega_{ff}^2 \left[ \Omega_{ij}^{\text{on}} - \Omega_{jj}^{\text{on}} \right] \quad (\Omega_{ff}^2) \geq 0. \tag{38}
$$

Based on eq. [\(9\)](#page-4-1), the block stress matrix  $\Omega_{ff}^+$  is established as follows.

<span id="page-12-0"></span>
$$
\Omega_{ff}^{+} = \begin{bmatrix} -\frac{\Omega_{ff}^{P1}}{1 - \frac{1}{2} - \frac
$$

where

$$
\Omega_{ff}^{P3+} \triangleq \left[\begin{array}{ccc} \Omega_{ii} + \frac{\varpi_{iu}^2}{\varpi_{uu}} & \Omega_{ij} + \frac{\varpi_{iu}\varpi_{ju}}{\varpi_{yu}} & -\varpi_{iu} \\ \Omega_{ij} + \frac{\varpi_{iu}\varpi_{ju}}{\varpi_{uu}} & \Omega_{jj} + \frac{\varpi_{ju}^2}{\varpi_{uu}} & -\varpi_{ju} \\ -\varpi_{iu} & -\varpi_{ju} & \varpi_{uu} \end{array}\right]
$$

Since  $\varpi_{uu} > 0$  and

$$
\begin{bmatrix}\n\Omega_{ii} + \frac{\varpi_{iu}^2}{\varpi_{uu}} & \Omega_{ij} + \frac{\varpi_{iu}\varpi_{ju}}{\varpi_{uu}} \\
\Omega_{ij} + \frac{\varpi_{iu}\varpi_{ju}}{\varpi_{uu}} & \Omega_{jj} + \frac{\varpi_{ju}^2}{\varpi_{uu}}\n\end{bmatrix} - \frac{1}{\varpi_{uu}}\n\begin{bmatrix}\n-\varpi_{iu} \\
-\varpi_{ju}\n\end{bmatrix}\n\begin{bmatrix}\n-\varpi_{iu} & -\varpi_{ju}\n\end{bmatrix} =\n\begin{bmatrix}\n\Omega_{ii} & \Omega_{ij} \\
\Omega_{ij} & \Omega_{jj}\n\end{bmatrix} \succ 0,
$$

we have  $\Omega_{ff}^{P3+} > 0$ . It follows from eq. [\(39\)](#page-12-0) and eq. [\(38\)](#page-12-1) that

$$
\Omega_{ff}^{P1} - \left[\begin{array}{cc} \mathbf{\Omega}_{ff}^{P2} & \mathbf{0} \end{array}\right] \left(\mathbf{\Omega}_{ff}^{P3+}\right)^{-1} \left[\begin{array}{c} \left(\mathbf{\Omega}_{ff}^{P2}\right)^T\\ \mathbf{0}_{1\times(n_f-2)} \end{array}\right] \succ 0. \tag{40}
$$

By applying Lemma [6](#page-10-10) again, we have  $\Omega_{ff}^+ \succ 0$ . • All the vertices  $v_i, v_j, v_k \in \mathcal{V}_f$ .

The analysis shares the same idea as in the above two cases. The block stress matrix  $\Omega_{ff}$  is positive definite and can be divided into

$$
\Omega_{ff} = \begin{bmatrix} -\frac{\Omega_{ff}^{P_1}}{L} - \frac{1}{\Omega_{ii}} - \frac{\Omega_{ff}^{P_2}}{\Omega_{ij}} - \frac{1}{\Omega_{ik}} \\ \left(\Omega_{ff}^{P_2}\right)^T & \Omega_{ij} & \Omega_{jj} & \Omega_{jk} \\ \frac{1}{\Omega_{ik}} - \frac{1}{\Omega_{jk}} - \frac{1}{\Omega_{jk}} \\ \frac{1}{\Omega_{jk}} & \Omega_{jk} & \Omega_{kk} \end{bmatrix} \succ 0.
$$

After adding a new vertex  $v_u$  as a follower, we have

$$
\Omega_{ff}^{+} = \begin{bmatrix} \Omega_{ff}^{P1} & \Omega_{ff}^{P2} & 0_{(n_f-3)\times 1} \\ (\Omega_{ff}^{P2})^T & | & \Omega_{ff}^{P3} \\ 0_{1\times (n_f-3)} & | & \Omega_{ff}^{P3} \end{bmatrix}
$$

where  $\Omega_{ff}^{P3+} = \begin{bmatrix} \Omega_{ff}^{P3} & 0 \\ 0 & 0 \end{bmatrix}$ 0 0  $+ \Omega_u$ . By applying Lemma [6](#page-10-10) again, we can prove the matrix  $\Omega_{ff}^+$  is

also positive definite.

According to Lemma [2,](#page-1-2) the stress matrix  $\Omega^+$  associated with the augmented framework  $(\mathcal{G}^+, p^+)$  follows that

$$
\left(\mathbf{\Omega}^+\otimes\mathbf{I}_d\right)\boldsymbol{p}^+=\left[\begin{array}{cc} \bar{\mathbf{\Omega}}_{ll}^+ & \bar{\mathbf{\Omega}}_{lf}^+ \\ \bar{\mathbf{\Omega}}_{fl}^+ & \bar{\mathbf{\Omega}}_{ff}^+ \end{array}\right]\left[\begin{array}{c} \boldsymbol{p}_l^+ \\ \boldsymbol{p}_f^+ \end{array}\right]=\mathbf{0}.\quad(41)
$$

Accordingly, we have  $\bar{\mathbf{\Omega}}_{fl}^+ \mathbf{p}_l^+ + \bar{\mathbf{\Omega}}_{ff}^+ \mathbf{p}_f^+ = \mathbf{0}$ . We clarify that the augmented framework  $(\mathcal{G}^+, p^+)$  is affinely localized by the selected leaders since  $\Omega_{ff}^+ > 0$ , which leads

$$
\text{to }\bm{p}_f^+=-\left(\bar{\bm{\Omega}}_{ff}^+\right)^{-1}\bar{\bm{\Omega}}_{fl}^+\bm{p}_l^+.
$$

With all the discussions above, the augmented framework  $(\mathcal{G}^+, p^+)$  obtained from adding a new  $v_u$  and three weighted edges meets the requirements for universal rigidity and affine localizability.
