(Dated: January 6, 2025)

In-plane magnetization is induced by the Edelstein effect in the Rashba spin-orbit interaction system. However, out-of-plane magnetization is more useful for switching a ferromagnetic memory. We study analytically and numerically electric-field induced magnetization in  $p$ -wave magnets with the aid of the Rashba interaction based on a simple two-band model. The out-of-plane magnetization is induced when the Néel vector of the p-wave magnet is along the z direction. We also show that no magnetization is induced in the absence of the Rashba interaction. The electric-field induced magnetization will be useful for future switching technology of ferromagnetic memories based on the p-wave magnet.

Introduction: Multiferroic effects are cross correlation effects in electromagnetic responses $[1-3]$  $[1-3]$ . One is the electric polarization induced by magnetic-field[\[4–](#page-3-2)[6\]](#page-3-3) and the other is the magnetization induced by electric field[\[7–](#page-3-4)[10\]](#page-3-5). Especially, the latter is important for the flip of a magnetic memory under the control of the external electric field. The Edelstein effect $[11, 12]$  $[11, 12]$  $[11, 12]$  is a promising way for it. It is based on the spin-momentum locked Fermi surface induced by the Rashba interaction<sup>[\[13\]](#page-3-8)</sup>. In the presence of the Rashba interaction, the spin direction depends on the angle of the momentum as shown in Fig[.1\(](#page-0-0)a), where the Fermi surface forms a perfect circle. By applying in-plane electric field, the Fermi distribution is shifted, which induces the imbalance in the spin accumulation. It results in the net inplane magnetization. However, out-of-plane magnetization is desirable for practical applications to ferromagnetic memories because ferromagnet points to out-of-plane direction. The Edelstein effect is confirmed in various experiments[\[14–](#page-3-9) [16\]](#page-3-10). It is also realized in semiconductors[\[17,](#page-3-11) [18\]](#page-3-12), Rashba-Dresselhaus systems[\[19,](#page-3-13) [20\]](#page-3-14), topological insulators[\[21,](#page-3-15) [22\]](#page-3-16), Weyl semimetals[\[23\]](#page-3-17).

Recently, a p-wave magnet was proposed based on firstprinciple calculations  $[24]$ , where the Fermi surface has the pwave symmetry. A material candidate is CeNiAsO. The system is described by a four-band tight-binding model. Subsequently, the Edelstein effect without the Rashba interaction was proposed in this magnet<sup>[\[25\]](#page-3-19)</sup>.

In this paper, we investigate the Edelstein effect in a two-dimensional system made of a p-wave magnet with the Rashba interaction, which is described by a simple two-band continuum model. By applying an in-plane electric field, we demonstrate the emergence of the out-of-plane magnetization provided the Néel vector of the p-wave magnet is taken perpendicular to the plane. Namely, it is possible to switch the out-of-plane magnetization by controlling the external inplane electric field. It would be useful for the switch of a ferromagnetic memory. Our results will open a new way to the magnetic-memory switching device by electric field.

Edelstein effect: The magnetization is induced by the change of the Fermi distribution in the Rashba system, which is called the Edelstein effect. We study such an effect by controlling external electric field E. We expand the Fermi distribution in powers of **E**,  $f = f^{(0)} + f^{(1)} + \cdots$ , where  $f^{(0)} =$  $1/ (\exp [(\varepsilon - \mu)/k_BT] + 1)$  is the Fermi distribution func-

<span id="page-0-0"></span>FIG. 1. (a1), (a2) and (a3) Fermi surfaces at  $\mu = 2\varepsilon_0$  in the  $(k_x, k_y)$ plane. The momentum axis is in units of  $k_0$ . (b1), (b2) and (b3) Energy spectrum along the x axis. The vertical axis is the energy  $\varepsilon$ in units of  $\varepsilon_0$ , while the horizontal axis is  $k_x$  in units of  $k_0$ . Purple lines represent  $\mu = 2\varepsilon_0$ . (a1) and (b1) Rashba model. (a2) and (b2) Out-of-plane p-wave magnet. (a3) and (b3) In-plane p-wave magnet. Red color represents  $S_y = 1$ , while cyan color represents  $S_y = -1$ in (a1), (b1), (a3) and (b3). On the other hand, red color represents  $S_z = 1$ , while cyan color represents  $S_z = -1$  in (a2) and (b2). Arrows represent the spin direction. We have set  $m = 4\hbar^2 k_0^2/\varepsilon_0$ ,  $J = 0.4\varepsilon_0/k_0$  and  $\lambda = 0.2\varepsilon_0/k_0$ .

tion,  $\mu$  is the chemical potential,  $\varepsilon$  is the energy, and  $f^{(1)}$  is the first-order perturbated Fermi distribution function as a function of E. By solving the Boltzmann equation, it is explicitly given by

$$
f^{(1)} = \frac{e\tau}{\hbar} \mathbf{E} \cdot \nabla_{\mathbf{k}} f^{(0)}, \tag{1}
$$

where  $\tau$  is the relaxation time. We focus on the linear response.

The magnetization is given by the formula $[25-36]$  $[25-36]$ 

$$
\mathbf{M} = \frac{e\tau}{\hbar} g\mu_{\text{B}} \int \frac{d^3k}{(2\pi)^3} \mathbf{S} \left(\mathbf{k}\right) f^{(1)},\tag{2}
$$

where  $\mathbf{S}(\mathbf{k}) \equiv \langle \psi_{\mathbf{k}} | \sigma | \psi_{\mathbf{k}} \rangle$  is the expectation value of the spin operator  $\sigma$ , g is the g factor, and  $\mu$ B is the Bohr magneton. The magnetization formula is rewritten as

$$
\mathbf{M} = \frac{e\tau}{\hbar} g \mu_{\mathbf{B}} \int \frac{d^3 k}{(2\pi)^3} \mathbf{S} \left( \mathbf{k} \right) \left( \mathbf{E} \cdot \nabla_{\mathbf{k}} \varepsilon \right) \frac{\partial}{\partial \varepsilon} f^{(0)}.
$$
 (3)

<span id="page-1-1"></span>FIG. 2. Out-of-plane Edelstein effect. (a1)  $\alpha_{zx}^{\text{ME}}$  and (a2)  $\alpha_{yx}^{\text{ME}}$  as a function of J. We have set  $\lambda = 0.2\varepsilon_0/k_0$ . (b1)  $\alpha_{xx}^{\text{ME}}$  and (b2)  $\alpha_{yx}^{\text{ME}}$ as a function of  $\lambda$ . We have set  $J = 0.2\varepsilon_0/k_0$ . Red curves represent the numerical results without using the perturbation theory. Blue and green lines represent the analytic results for  $\alpha_{zx}^{\text{ME}}$  and  $\alpha_{yx}^{\text{ME}}$  in Eq.[\(13\)](#page-2-0), respectively.  $\alpha_{xx}^{\text{ME}}, \alpha_{yx}^{\text{ME}}$  and  $\alpha_{zx}^{\text{ME}}$  are in units of  $\frac{g\mu_B k_0}{\hbar W}$ , while J and  $\lambda$  are in units of  $\varepsilon_0/k_0$ . We have set  $\mu = 2\varepsilon_0$  and  $m = 4\hbar^2 k_0^2/\varepsilon_0$ .

At zero temperature, it is given by

$$
\mathbf{M} = e\tau g \mu_{\mathbf{B}} \int \frac{d^3 k}{\left(2\pi\right)^3} \mathbf{S}\left(\mathbf{k}\right) \left(\mathbf{E} \cdot \mathbf{v}\right) \delta\left(\varepsilon_{\mathbf{k}} - \mu\right), \quad (4)
$$

where we have defined the velocity operator  $\hbar \mathbf{v} = \nabla_{\mathbf{k}} \varepsilon$ .

We apply the electric field along the  $x$  axis in the twodimensional system. When there are two Fermi surfaces  $k_{+}(\phi)$  around the origin as illustrated in Fig[.1,](#page-0-0) it is rewritten as

<span id="page-1-0"></span>
$$
\mathbf{M} = \frac{e\tau g\mu_{\mathbf{B}}E_x}{\left(2\pi\right)^2 W} \sum_{\pm} \int kdkd\phi \mathbf{S} \left(\mathbf{k}\right) v_x \frac{\delta\left(k_{\pm}\left(\phi\right) - k\right)}{\left|\frac{\partial \varepsilon}{\partial k}\right|}, \tag{5}
$$

or

$$
M_i = e\tau \alpha_{ij}^{\text{ME}} E_j,\tag{6}
$$

in terms of the magnetoelectric susceptibility  $\alpha_{ij}^{\text{ME}}$  given by

<span id="page-1-2"></span>
$$
\alpha_{ix}^{\text{ME}} = \frac{g\mu_{\text{B}}}{\left(2\pi\right)^2 W} \sum_{\pm} \int d\phi \left. \frac{k v_x S_i \left(\mathbf{k}\right)}{\left|\frac{\partial \varepsilon}{\partial k}\right|} \right|_{k=k_{\pm}(\phi)}, \quad (7)
$$

where  $k_{\pm}(\phi)$  is obtained by solving  $\varepsilon$   $(k_{\pm}(\phi)) = \mu$ ,  $v_x = \frac{\partial \varepsilon}{\hbar \partial k_x}$  is the velocity along the x axis,  $W^{-1} \equiv \int dk/(2\pi)$ is the width of the sample, and we have introduced the polar coordinate  $k_x = k \cos \phi$ ,  $k_y = k \sin \phi$ .

Out-of-plane  $p$ -wave Edelstein effects: We consider a two-dimensional system made of the p-wave magnet with the Rashba interaction. The simplest model is a two-band model consisting of the free-electron term, the Rashba term[\[37–](#page-4-1)[45\]](#page-4-2) and the *p*-wave term $[24, 37, 46-49]$  $[24, 37, 46-49]$  $[24, 37, 46-49]$  $[24, 37, 46-49]$  $[24, 37, 46-49]$  $[24, 37, 46-49]$ , which is realized as a heterostructure of a magnet on a substrate. The Hamiltonian is given by[\[37\]](#page-4-1),

<span id="page-1-4"></span>
$$
H(\mathbf{k}) = \frac{\hbar^2 (k_x^2 + k_y^2)}{2m} \sigma_0 + \lambda (k_x \sigma_y - k_y \sigma_x) + J k_x \mathbf{n} \cdot \sigma, \tag{8}
$$

<span id="page-1-3"></span>FIG. 3. Out-of-plane Edelstein effect. (a1) Bird's eye's view of  $\alpha_{zx}^{\text{ME}}$ in the  $J-\lambda$  plane, and (b1) its color plot. (a2) Bird's eye's view of  $\alpha_{yx}^{\text{ME}}$  in the J- $\lambda$  plane, and (b2) its color plot. Green line represents the condition  $\lambda = 0$  and the purple line represents the condition  $J = 0$ . See the caption of Fig.2 for the units of various variables. We have set  $\mu = 2\varepsilon_0$  and  $m = 4\hbar^2 k_0^2/\varepsilon_0$ .

where m is the effective mass of free electrons,  $\lambda$  is the magnitude of the Rashba interaction, and n is the p-wave Néel vector with  $J$  its magnitude. The Rashba interaction is introduced by placing a sample on the substrate. We study the case where the Néel vector is along the z direction,  $\mathbf{n} = (0, 0, 1)$ .

The energy spectrum is given by

$$
\varepsilon_{\pm} = \frac{\hbar^2 k^2}{2m} \pm k \sqrt{F(\phi)},\tag{9}
$$

with

$$
F(\phi) \equiv \lambda^2 + J^2 \cos^2 \phi. \tag{10}
$$

The expectation value of the spin operator  $S(k)$  is determined as

$$
S_x^{\pm} = \mp \frac{\lambda \sin \phi}{\sqrt{F(\phi)}}, \quad S_y^{\pm} = \pm \frac{\lambda \cos \phi}{\sqrt{F(\phi)}}, \quad S_z^{\pm} = \pm \frac{J \cos \phi}{\sqrt{F(\phi)}},
$$
(11)

which does not depend on  $k$  and shown in Fig[.1\(](#page-0-0)a3).

The integrand of Eq.[\(5\)](#page-1-0) is given analytically. By integrating it over  $\phi$  numerically, we obtain the susceptibility  $\alpha_{ix}^{\text{ME}}$ . We show the components  $\alpha_{zx}^{\text{ME}}$  and  $\alpha_{yx}^{\text{ME}}$  in Fig[.2,](#page-1-1) while  $\alpha_{xx}^{\text{ME}} = 0$ .

We derive an analytic formula for the susceptibility up to the first-order in J and  $\lambda$ . There are two Fermi surfaces  $k_{\pm}(\phi)$ as shown in Fig[.1\(](#page-0-0)a). The outer Fermi surface  $k_-(\phi)$  and the inner Fermi surface  $k_{+}$  ( $\phi$ ) are given by

$$
\hbar k_{\pm}(\phi) = \sqrt{2\mu m} \mp mJ\cos\phi,\tag{12}
$$

<span id="page-2-2"></span>FIG. 4. In-plane Edelstein effect. (a)  $\alpha_{yx}^{\text{ME}}$  as a function of J. We have set  $\lambda = 0.2\varepsilon_0/k_0$ . b)  $\alpha_{yx}^{\text{ME}}$  as a function of  $\lambda$ . We have set  $J =$  $0.2\varepsilon_0/k_0$ . Red curves represent the numerical results without using the perturbation theory. Blue lines represent the analytic results Eq. [\(18\)](#page-2-1) based on the perturbation theory. See the caption of Fig.2 for the units of various variables. We have set  $\mu = 2\varepsilon_0$  and  $m = 4\hbar^2 k_0^2/\varepsilon_0$ .

which are shown in color in Fig[.1\(](#page-0-0)a). The  $y$  spin polarization is maximized along the x axis ( $\phi = 0, \pi$ ).

The susceptibility [\(7\)](#page-1-2) is calculated as

<span id="page-2-0"></span>
$$
\alpha_{xx}^{\text{ME}} = 0, \quad \alpha_{yx}^{\text{ME}} = -\frac{g\mu_{\text{B}}m}{2\pi\hbar^3 W} \lambda, \quad \alpha_{zx}^{\text{ME}} = -\frac{g\mu_{\text{B}}m}{2\pi\hbar^3 W} J \tag{13}
$$

for  $\mu > 0$  up to the first order in J and  $\lambda$ , which are shown as the blue and green lines in Fig[.2,](#page-1-1) respectively.

We show the numerically obtained susceptibility in the  $J-\lambda$ plane in Fig[.3.](#page-1-3) Eq.[\(13\)](#page-2-0) agrees well with the numerical result for small  $J/\lambda$ . We find that  $\alpha_{zx}^{\text{ME}} = 0$  along the lines  $J = 0$ and  $\lambda = 0$  as in Fig[.3\(](#page-1-3)b1), while  $\alpha_{yx}^{\text{ME}} = 0$  along the line  $\lambda = 0$ . The susceptibility  $\alpha_{zx}^{\text{ME}}$  is positive for  $J < 0$  and negative for  $J > 0$ , where the sign of  $\alpha_{zx}^{\text{ME}}$  does not depend on  $\lambda$ . On the other hand,  $\alpha_{yx}^{\text{ME}}$  is positive for  $\lambda < 0$  and negative for  $\lambda > 0$ , where the sign of  $\alpha_{yx}^{\text{ME}}$  does not depend on J.

In-plane  $p$ -wave magnet: We next study the case where the Néel vector is along the  $y$  direction. The energy spectrum is given by

$$
\varepsilon_{\pm} = \frac{\hbar^2 k^2}{2m} \pm k \sqrt{G\left(\phi\right)},\tag{14}
$$

with

$$
G(\phi) \equiv \lambda^2 \sin^2 \phi + (J + \lambda)^2 \cos^2 \phi.
$$
 (15)

The Fermi surface is shown in Fig[.1\(](#page-0-0)a3). There are two Fermi surfaces  $k_{+}(\phi)$ . The outer Fermi surface  $k_{-}(\phi)$  and the inner Fermi surface  $k_{+}(\phi)$  are analytically given by

$$
\hbar k_{\pm}(\phi) = \sqrt{2\mu m} \mp m\lambda + J\left(m \mp \frac{m\sqrt{m}\lambda}{\sqrt{2\mu}}\right) \cos^2\phi
$$
 (16)

up to the first order in J and  $\lambda$ . The spin direction is

$$
S_{\pm}^{y} = \pm \frac{(J+\lambda)x}{\sqrt{G(\phi)}}.\tag{17}
$$

The susceptibility [\(7\)](#page-1-2) is calculated as

<span id="page-2-1"></span>
$$
\alpha_{yx}^{\text{ME}} = -\frac{mg\mu_{\text{B}}}{4\pi\hbar^3 W} \left( J + 2\lambda \right), \qquad \alpha_{xx}^{\text{ME}} = \alpha_{zx}^{\text{ME}} = 0 \quad (18)
$$

for  $\mu > 0$  up to the first order in J and  $\lambda$ , which is shown as the blue lines in Fig[.4.](#page-2-2)

<span id="page-2-3"></span>FIG. 5. In-plane Edelstein effect. Bird's eye's view of  $\alpha_{yx}^{\text{ME}}$  in the  $J-\lambda$  plane, and (b) its color plot. Green line represents the condition  $\lambda = 0$  and the purple line represents the condition  $\lambda + J = 0$ . See the caption of Fig.2 for the units of various variables. We have set  $\mu = 2\varepsilon_0$  and  $m = 4\hbar^2 k_0^2/\varepsilon_0$ .

We show the numerically obtained susceptibility in Fig[.4.](#page-2-2) Eq.[\(18\)](#page-2-1) agrees well with the numerical result for small  $J/\lambda$ . The susceptibility is zero  $\alpha_{ix}^{\text{ME}} = 0$  for  $\lambda = 0$  or  $J + \lambda = 0$ as shown in Fig[.4\(](#page-2-2)a) and (b), where the Hamiltonian  $(8)$  is diagonal. The susceptibility  $\alpha_{yx}^{\text{ME}}$  is positive for  $J + \lambda < 0$ and negative for  $J + \lambda > 0$  as shown in in Fig[.5\(](#page-2-3)a) and (b). It is because the spin direction along the  $x$  axis matters for the electric-field induced magnetization. On the other hand, the sign of the susceptibility  $\alpha_{yx}^{\text{ME}}$  does not change at  $\lambda = 0$ because  $f^{(1)}(0, k_y) = 0$ .

Discussion: We investigated the electric-field induced magnetization in a simple two-band  $p$ -wave magnet model, where the Rashba interaction is essential. On the other hand, the electric-field induced magnetization was shown to occur without the Rashba interaction in the *p*-wave magnet system described by the four-band model $[24, 25]$  $[24, 25]$  $[24, 25]$ 

$$
H = 2t \left( \tau_x \cos \frac{k_x}{2} + \cos k_y \right)
$$

$$
+ 2t_J \left( \sigma_x \tau_y \sin \frac{k_x}{2} + \sigma_y \tau_z \cos k_y \right), \quad (19)
$$

where  $\sigma$  and  $\tau$  correspond to the spin and site degrees of freedom.

The above four-band model is derived for a specific material candidate CeNiAsO[\[24\]](#page-3-18), which is a metal. The dependence of the pseudospin  $\tau$  enters in a specific way, and hence, this four-band Hamiltonian is applicable to a specific case. On the other hand, the two-band Hamiltonian  $(8)$  is quite universal. There are two possibilities to realize the model. One is the metallic  $p$ -wave magnet without the pseudospin degrees of freedom on a substrate producing the Rashba interaction. The other is the insulating *p*-wave magnet, where free electrons exist away from the  $p$ -wave magnet, while the interface produces the Rashba interaction. Our results will open a new way to multiferroics based on the p-wave magnet.
