ON SYMMETRIES IN ANALYTIC INPUT-OUTPUT SYSTEMS

W. STEVEN GRAY AND ERIK I. VERRIEST

Abstract. There are many notions of symmetry for state space models. They play a role in understanding when systems are time reversible, provide a system theoretic interpretation of thermodynamics, and have applications in certain stabilization and optimal control problems. The earliest form of symmetry for analytic input-output systems is due to Fliess who introduced systems described by an *exchangeable* generating series. In this case, one is able to write the output as a memoryless analytic function of the integral of each input. The first goal of this paper is to describe two new types of symmetry for such Chen–Fliess input-output systems, namely, coefficient reversible symmetry and palindromic symmetry. Each concept is then related to the notion of an exchangeable series. The second goal of the paper is to provide an in-depth analysis of Chen–Fliess input-output systems whose generating series are linear time-varying, palindromic, and have generating series coefficients growing at a maximal rate while ensuring some type of convergence. It is shown that such series have an infinite Hankel rank and Lie rank, have a certain infinite dimensional state space realization, and a description of their relative degree and zero dynamics is given.

Keywords: Chen–Fliess series, nonlinear control

1. INTRODUCTION

Symmetry in the context of control theory has a long history beginning with the work of Brockett and (J. L.) Willems who demonstrated that linear time-invariant (LTI) systems with block circulant symmetry appear naturally in lumped approximations of distributed systems [\(Brockett & Willems, 1975\)](#page-23-1). Subsequently, many different notions of symmetry have emerged depending on the underlying model involved and the application being pursed. Roughly speaking, the existing definitions break down into concepts best suited for LTI systems and those aimed at more general classes of systems

In the context of LTI systems, there was the early work of (J. C.) Willems who introduced the behavioral approach to system modeling and defined the property of *time-reversal sym*metry as one where the time-reversed version of any input-output pair of a given system is also an admissible input-output pair for the system [\(Willems, 1978\)](#page-25-0). The question at the time was what type of structure does this kind of symmetry impose on any finite dimensional linear state space realization of the input-output map. These ideas were further developed by [Fagnani & Willems \(1991\)](#page-23-2) and later expanded to other forms of symmetry using transformations groups [\(Fagnani & Willems, 1993,](#page-23-3) [1994\)](#page-23-4). A second notion of time-reversal symmetry was initiated by [Bernstein & Bhat \(2003\)](#page-23-5) who considered *output reversal symmetry* of the free response of a linear dynamical system with an output map. This property is characterized by the feature that if an output is in the range of the initial state-to-output map, then its time-reversed version is also in the range of this map. The aim here was to provide a system theoretic interpretation of thermodynamics. This program was later fully realized by [Haddad, et al. \(2005,](#page-24-0) [2008\)](#page-24-1); [Nersesov & Haddad \(2008\)](#page-25-1); [Nersesov, et al. \(2012,](#page-25-2) [2014\)](#page-25-3). A third type of symmetry appearing in the LTI case is that of palindromic symmetry in system parameterizations. This is defined in terms of palindromic polynomials appearing in the transfer function [\(Butkovskii, 1994\)](#page-23-6). This leads to yet another definition of timereversibility [\(Markovsky & Rao, 2008\)](#page-24-2) and turns out to be useful, for example, in certain types of stabilization problems [\(Volinsky & Shklyar, 2023\)](#page-25-4). A final kind of symmetry in the LTI setting is that of algebraic symmetry [\(Martin, 1982;](#page-24-3) [Hazewinkel & Martin, 1983,](#page-24-4) [1984\)](#page-24-5). The main idea here is that systems composed of identical interacting subsystems have an underlying *symmetry algebra*. This structure allows one to define a system over an algebra in a natural way so that problems like stabilization can be solved while preserving the intrinsic structure of the plant.

The earliest notion of symmetry for more general classes of systems is due to Fliess in the context of analytic input-output systems written in terms of weighted sums of iterated integrals, what is now called a *Chen–Fliess series* [\(Fliess, 1981,](#page-23-7) [1983\)](#page-23-8). The weights or coefficients of such a functional series are indexed by words over a finite alphabet and define a noncommutative formal power series or generating series. A generating series is said to be exchangeable if every coefficient is invariant under any permutation of the letters in its index (see Definition [3.4\)](#page-7-0) [\(Fliess, 1974,](#page-23-9) [1981\)](#page-23-7). This type of symmetry for generating series is equivalent to being able to write its corresponding Chen–Fliess series as a memoryless analytic function of the integral of each input. Other lines of research in this area provide notions of symmetry in the state space setting. For physical systems constrained by conservation laws, it was shown by [van der Schaft \(1981,](#page-25-5) [1983,](#page-25-6) [1984,](#page-25-7) [1987\)](#page-25-8) that notions of symmetry can be used to simplify and solve optimal control problems. Conversely, conditions can be identified for Hamiltonian systems under which they possess time-reversal symmetry in the sense of [Willems \(1978\)](#page-25-0). More general types of state space symmetry were developed by Grizzle $\&$ [Marcus \(1984,](#page-24-6) [1985\)](#page-24-7) in terms of symmetry groups acting on realizations in order to decompose the system into lower dimensional subsystems. The motivation was to simplify the analysis of the original system by investigating the properties of these simpler subsystems.

The first goal of this paper is to describe two new types of symmetry for Chen–Fliess input-output systems, namely, coefficient reversible symmetry and palindromic symmetry. Coefficient reversible symmetry refers to systems whose generating series are invariant when the indices of the coefficients are written in reverse order. This concept is close in spirit to palindromic polynomials used in the analysis of LTI systems but involves a noncommuting alphabet. It is shown that such systems have a type of input reversal symmetry. That is, the output value at time t is unchanged when the input is time-reversed on the interval $[0, t]$. Palindromic symmetry refers to the subclass of coefficient reversible series with the defining property that every word in the support of a given generating series is a palindrome. LTI systems never possess this type of symmetry (see Example [3.6\)](#page-10-1). Palindromic words have a long history in theoretical computer science [\(Droubay & Pirillo, 1999\)](#page-23-10). More recently, DNA palindromes in the human genome have been identified as playing a role in carcinogenesis (Miklenić & Svetec, 2021). Their presence in the SARS-CoV-2 virus was used as a rapid detection tool to track the evolution of the virus during the pandemic [\(Ghosh, et al., 2022\)](#page-23-11). Palindromes are also used in the genome editing technology CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats) [\(Jinek, et al., 2012\)](#page-24-9). But their appearance in the context of system theory appears to be new. Finally, these two types of series symmetry are related to the existing and distinct notion of exchangeable series.

The second goal of the paper is to provide an in-depth analysis of Chen–Fliess inputoutput systems whose generating series are linear time-varying and palindromic. A specific instance of this type of generating series was used by [Gray & Verriest \(2023\)](#page-24-10) to show that a class of functional differential equations are well suited for describing such systems. That example is generalized here in Sections [4.1](#page-11-0) and [4.2](#page-12-0) to series that are *globally maximal* in a sense to be described. It is shown that their generating series are algebraic but are neither rational nor possess finite Lie rank. Nevertheless, the input-output map does have an infinite dimensional, linear time-varying state space realization in terms of Bessel functions of the first kind. The corresponding impulse response can be described in terms of a modified Bessel function of the first kind. The problem of zeroing the output of this operator is then addressed when an arbitrary zero-input response is added to the output. By purely algebraic means it is shown that the nulling input can be written in terms of a Neumann series of Bessel functions [\(Jankov, et al., 2011;](#page-24-11) [Wilkins, 1948\)](#page-25-9). Once this input is identified, it is shown that the state space realization has relative degree one, and the zero dynamics are explicitly described [\(Isidori, 1995\)](#page-24-12). Next, a class of palindromic linear systems that are convergent only in a local sense are characterized. The same three problems are addressed, namely, the Hankel rank and Lie rank of the generating series are shown to be infinite, an infinite dimensional state space realization is presented, and a description of the relative degree and zero dynamics of such systems are given. These problems are more difficult since the impulse response exhibits singularities, and the role of the Bessel functions is superseded by generalized hypergeometric functions.

The paper is organized as follows. The next section summarizes some mathematical preliminaries to establish the notation and terminology. Section [3](#page-6-0) then presents the two new notions of symmetry for (generating) formal power series. The characterization of globally maximal palindromic linear systems is developed in Section [4.](#page-10-0) Section [5](#page-17-0) presents the analogous results for the local case. The conclusions of the paper are given in the final section.

2. Preliminaries

An alphabet $X = \{x_0, x_1, \ldots, x_m\}$ is any nonempty finite set of symbols referred to as letters. A word $\eta = x_{i_1} x_{i_2} \cdots x_{i_k}$ is a finite sequence of letters from X. The number of letters in a word η , written as $|\eta|$, is called its *length*. The empty word, \emptyset , has length zero. The collection of all words is denoted by X^* and constitutes a noncommutative monoid under concatenation. Given any nonempty word η , let ηX^* be the set of all words with the prefix η . Any mapping $c: X^* \to \mathbb{R}^{\ell}$ is called a *formal power series*. It is often written as the formal sum $c = \sum_{\eta \in X^*} (c, \eta) \eta$, where the *coefficient* $(c, \eta) \in \mathbb{R}^{\ell}$ is the image of $\eta \in X^*$ under c. The support of c, $supp(c)$, is the set of all words having nonzero coefficients. A series is proper if supp (c) does not contain the empty word. The set of all noncommutative formal power series over the alphabet X is denoted by $\mathbb{R}^{\ell} \langle \langle X \rangle \rangle$. The subset of series with finite support, i.e., polynomials, is represented by $\mathbb{R}^{\ell} \langle X \rangle$.

2.1. Chen–Fliess series. Given any $c \in \mathbb{R}^{\ell} \langle \langle X \rangle \rangle$, one can associate a functional series, F_c , in the following manner. Let $p \geq 1$ and $t_0 < t_1$ be given. For a Lebesgue measurable function $u: [t_0, t_1] \to \mathbb{R}^m$, define $||u||_{\mathfrak{p}} = \max{||u_i||_{\mathfrak{p}} : 1 \leq i \leq m}$, where $||u_i||_{\mathfrak{p}}$ is the usual $L_{\mathfrak{p}}$ -norm for a measurable real-valued function, u_i , defined on $[t_0, t_1]$. Let $L_{\mathfrak{p}}^m[t_0, t_1]$ denote the set of all measurable functions defined on $[t_0, t_1]$ having a finite $\lVert \cdot \rVert_{\mathfrak{p}}$ norm and $B^m_{\mathfrak{p}}(R)[t_0, t_1] := \{u \in$ $L_{\mathfrak{p}}^m[t_0,t_1]: ||u||_{\mathfrak{p}} \leq R$. Assume $C[t_0,t_1]$ is the subset of continuous functions in $L_1^m[t_0,t_1]$. Define inductively for each word $\eta = x_i \bar{\eta} \in X^*$ the map $E_{\eta}: L_1^m[t_0, t_1] \to C[t_0, t_1]$ by setting $E_{\emptyset}[u] = 1$ and letting

$$
E_{x_i\bar{\eta}}[u](t,t_0) = \int_{t_0}^t u_i(\tau) E_{\bar{\eta}}[u](\tau,t_0) d\tau,
$$

where $x_i \in X$, $\bar{\eta} \in X^*$, and $u_0 = 1$. The *Chen–Fliess series* corresponding to $c \in \mathbb{R}^{\ell} \langle \langle X \rangle \rangle$ is

(1)
$$
y(t) = F_c[u](t) = \sum_{\eta \in X^*} (c, \eta) E_{\eta}[u](t, t_0)
$$

[\(Fliess, 1981\)](#page-23-7). To establish the convergence of this series, assume there exist real numbers $K, M > 0$ such that

(2)
$$
|(c, \eta)| \le KM^{|\eta|} |\eta|!, \ \forall \eta \in X^*.
$$

(Define $|z| = \max_i |z_i|$ whenever $z \in \mathbb{R}^{\ell}$.) It is shown by [Gray & Wang \(2002\)](#page-24-13) that under such circumstances the series (1) converges uniformly and absolutely so that F_c describes a well defined mapping from $B_{\mathfrak{p}}^m(R)[t_0, t_0+T]$ into $B_{\mathfrak{q}}^{\ell}(S)[t_0, t_0+T]$ for sufficiently small $R, T > 0$, where $\mathfrak{p}, \mathfrak{q} \in [1, \infty]$ satisfy $1/\mathfrak{p} + 1/\mathfrak{q} = 1$. The operator F_c is said to be *locally* convergent and is called a Fliess operator. The collection of all generating series c satisfying the growth condition [\(2\)](#page-4-2) is denoted by $\mathbb{R}_{LC}^{\ell} \langle \langle X \rangle \rangle$. A series $c \in \mathbb{R}_{LC} \langle \langle X \rangle \rangle$ is called *locally* maximal when it has the form $c = \sum_{\eta \in X^*} KM^{|\eta|} |\eta|! \eta$ (see Definition [3.5\)](#page-8-0). It provides a lower bound on the radius of convergence as described by [Thitsa & Gray \(2012\)](#page-25-10) for any Fliess operator whose coefficients satisfy (2) . When c complies with the more restrictive growth condition

(3)
$$
|(c, \eta)| \le KM^{|\eta|}(|\eta|!)^s, \ \forall \eta \in X^*,
$$

with $s \in [0, 1)$, the series [\(1\)](#page-4-1) defines an input-output operator from the L_p extended space

$$
L_{\mathfrak{p},e}^m(t_0) := \{ u : [t_0, \infty) \to \mathbb{R}^m : u_{[t_0, t_1]} \in L_{\mathfrak{p}}^m[t_0, t_1], \ \forall t_1 \in (t_0, \infty) \}
$$

into $C[t_0,\infty)$, where $u_{[t_0,t_1]}$ is taken as the restriction of the input u to the interval $[t_0,t_1]$ [\(Winter-Arboleda, et al., 2015\)](#page-26-0). The operator F_c in this case is called *globally convergent*, and the set of all generating series with a growth bound [\(3\)](#page-4-3) is denoted by $\mathbb{R}^{\ell}_{GC}(\langle X \rangle)$. A series $c \in \mathbb{R}_{GC} \langle \langle X \rangle \rangle$ will be called *globally maximal* when $c = \sum_{\eta \in X^*} KM^{|\eta|} \eta$.

2.2. Differential representations. A series $c \in \mathbb{R}^{\ell} \langle \langle X \rangle \rangle$ is said to have a *differential* representation when there exists a $z_0 \in \mathbb{R}^n$, a smooth function $h : \mathbb{R}^n \to \mathbb{R}^{\ell}$ defined on a neighborhood W of z_0 , and an m-tuple of smooth vector fields (g_0, g_1, \ldots, g_m) defined on W such that for any word $\eta = x_{i_k} \cdots x_{i_1} \in X^*$

$$
(c_j, \eta) = L_{g_{\eta}} h_j(z_0) := L_{g_{i_1}} \cdots L_{g_{i_k}} h_j(z_0),
$$

 $j = 1, 2, \ldots, \ell$, where $L_{g_i} h_j$ is the Lie derivative of h_j with respect to g_i . Such a representation can also be only formal when all the functions involved are formal, i.e., defined by possibly nonconvergent Taylor series at z_0 . In which case, the derivatives are interpreted as leftshifts on the Taylor series, and the Chen–Fliess series is a formal sum. In either case, the input-output map $y = F_c[u]$ has a control-affine state space realization

$$
\dot{z} = g_0(z) + \sum_{i=1}^m g_i(z)u_i, \ z(0) = z_0
$$

$$
y = h(z).
$$

The existence of a differential representation is established using the following concept.

Definition 2.1. [\(Fliess, 1974\)](#page-23-9) Given any $c \in \mathbb{R}^{\ell} \langle\langle X \rangle\rangle$, the $\mathbb{R}\text{-}linear$ mapping $\mathcal{H}_c : \mathbb{R}\langle X \rangle \to$ $\mathbb{R}^{\ell} \langle\langle X \rangle\rangle$ uniquely specified by $(\mathcal{H}_c(\eta), \xi) = (c, \xi \eta), \forall \xi, \eta \in X^*$ is called the **Hankel mapping** of c.

A series $c \in \mathbb{R}^{\ell} \langle \langle X \rangle \rangle$ is said to have finite Lie rank $\rho_L(c)$ when the vector space $\mathcal{H}_c(\mathcal{L}(X))$ has dimension $\rho_L(c)$, where $\mathcal{L}(X) \subset \mathbb{R}\langle X \rangle$ is the free Lie algebra over X. It is well known that c has a differential representation if and only if c has finite Lie rank [\(Fliess, 1981,](#page-23-7) [1983;](#page-23-8) [Isidori, 1995;](#page-24-12) [Jakubczyk, 1980,](#page-24-14) [1986a](#page-24-15)[,b;](#page-24-16) [Sussmann, 1977,](#page-25-11) [1990\)](#page-25-12). All minimal representations have dimension $\rho_L(c)$ and are unique up to a diffeomorphism.

In the event that $c \in \mathbb{R}\langle\langle X\rangle\rangle$ and the vector space $\mathcal{H}_c(\mathbb{R}\langle X\rangle)$ has finite dimension $\rho_H(c)$, then c has Hankel rank $\rho_H(c)$ and a differential representation where all the vector fields are linear. That is,

(4)
$$
(c, x_{i_k} \cdots x_{i_1}) = CN_{i_k} \cdots N_{i_1} z_0,
$$

where C, N_i , and z_0 are matrices with real coefficient and of dimension $1 \times \rho_H(c)$, $\rho_H(c) \times$ $\rho_H(c)$, and $\rho_H(c) \times 1$, respectively [\(Fliess, 1974,](#page-23-9) [1981;](#page-23-7) [Isidori, 1995\)](#page-24-12). It is well known that a series $c \in \mathbb{R} \langle \langle X \rangle \rangle$ is *rational* if and only if it has a linear representation [\(4\)](#page-5-1) [\(Berstel &](#page-23-12) [Reutenauer, 1988;](#page-23-12) [Fliess, 1981;](#page-23-7) [Salomaa & Soittola, 1978\)](#page-25-13). In addition, any system $y = F_c[u]$ with c rational has a bilinear realization

$$
\dot{z} = N_0(z) + \sum_{i=1}^{m} N_i(z)u_i, \ z(0) = z_0
$$

$$
y = Cz.
$$

2.3. Algebraic formal power series. A generalization of rational series is the class of algebraic series. Such series are characterized by being a solution to a system of polynomial equations as described below.

Definition 2.2. [\(Salomaa & Soittola, 1978;](#page-25-13) Schützenberger, 1962) Let $Z = \{z_1, z_2, \ldots, z_n\}$ be an alphabet disjoint from alphabet X. A **proper R-algebraic system** is a set of equations $z_i = p_i$, $i = 1, 2, \ldots, n$ such that:

$$
(1) \ \ p_i \in \mathbb{R} \langle X \cup Z \rangle
$$

(2) $(p_i, \emptyset) = 0$ and $(p_i, z_j) = 0, \forall i, j$.

A strong solution to (p_1, p_2, \ldots, p_n) is an *n*-tuple of proper series $c = (c_1, c_2, \ldots, c_n)$ $\mathbb{R}\langle\langle X\rangle\rangle^n$ computed inductively from the given set of equations such that $c_i = p_i(X, Z)|_{Z_i = c_i}$. Each c_i is called a *component* of c. Every proper R-algebraic system is known to have a unique solution. A series $d \in \mathbb{R} \langle \langle X \rangle \rangle$ is called \mathbb{R} -algebraic if its proper part $d - (d, \emptyset)$ is a component of a proper R-algebraic system. Every rational series is a solution to a proper R-algebraic system of linear equations. Thus, algebraic series and differentially generated series share a common subset, i.e., rational series. A representation theory for algebraic series is well known [\(Shamir, 1967;](#page-25-15) [Petre & Salomaa, 2009\)](#page-25-16), but it will not be so useful in the present context.

3. Three classes of symmetric formal power series

Three classes of formal power series are defined in this section, each with a certain kind of symmetry: coefficient reversible series, palindromic series, and exchangeable series.

Let $X = \{x_0, x_1, \ldots, x_m\}$ and define the following involution on the set of words X^* :

$$
\sim:\eta=x_{i_1}x_{i_2}\cdots x_{i_k}\in X^*\mapsto\tilde{\eta}=x_{i_k}x_{i_{k-1}}\cdots x_{i_1}.
$$

Linearly extend this map to $\mathbb{R}\langle\langle X\rangle\rangle$ so that $\tilde{c} = \sum_{\eta \in X^*} (c, \eta)\tilde{\eta}$.

Definition 3.1. A series $c \in \mathbb{R} \langle \langle X \rangle \rangle$ is coefficient reversible if

$$
(c, \eta) = (c, \tilde{\eta}), \ \forall \eta \in X^*.
$$

Example 3.1. The polynomial $c = x_0x_1 + x_1x_0$ is coefficient reversible while $d = x_0x_1$ is not. \Box

Lemma 3.1. A series is coefficient reversible if and only if $\tilde{c} = c$.

Proof: Suppose $c = \sum_{\eta \in X^*} (c, \eta) \eta$ is coefficient reversible. Then

$$
\tilde{c} = \sum_{\eta \in X^*} (c, \eta)\tilde{\eta} = \sum_{\eta \in X^*} (c, \tilde{\eta})\tilde{\eta} = \sum_{\tilde{\eta} \in X^*} (c, \tilde{\eta})\tilde{\eta} = c
$$

using the fact that \sim is bijective. Conversely, if $\tilde{c} = c$, then directly

$$
\sum_{\eta \in X^*} (c, \eta) \tilde{\eta} = \sum_{\eta \in X^*} (c, \eta) \eta = \sum_{\tilde{\eta} \in X^*} (c, \tilde{\eta}) \tilde{\eta} = \sum_{\eta \in X^*} (c, \tilde{\eta}) \tilde{\eta},
$$

which implies that

$$
(c, \eta) = (c, \tilde{\eta}), \ \forall \eta \in X^*.
$$

Г

Definition 3.2. An input-output map $F: u \mapsto y$ defined on [0, T] is called **input reversible** if for every $t \in [0, T]$

$$
y(t) = F[u](t) = F[u_t](t),
$$

where $u_t(\tau) = u(t - \tau)$ on [0, t].

Lemma 3.2. For $c \in \mathbb{R}_{LC} \langle \langle X \rangle \rangle$ and admissible u, $F_c[u](t) = F_{\tilde{c}}[u_t](t)$ for every t in the interval of convergence $(0, T)$.

Proof: For any $t \in [0, T]$ and admissible u observe

$$
F_{\tilde{c}}[u_t](t) = \sum_{\eta \in X^*} (c, \eta) E_{\tilde{\eta}}[u_t](t, 0).
$$

The assertion is that $E_{\tilde{\eta}}[u_t](t,0) = E_{\eta}[u](t,0)$, which would prove the lemma. The claim is trivial when $\eta = \emptyset$. In the case where $\eta = x_{i_1} x_{i_2} \cdots x_{i_k}$, observe

$$
E_{\eta}[u](t,0) = E_{x_{i_1}x_{i_2}\cdots x_{i_k}}[u](t,0)
$$

$$
= \int_0^t \int_0^{\tau_1} \cdots \int_0^{\tau_{k-1}} u_{i_1}(\tau_1) u_{i_2}(\tau_2) \cdots u_{i_k}(\tau_k) d\tau_k d\tau_{k-1} \cdots d\tau_1
$$

=
$$
\int_0^t \int_0^t \cdots \int_0^t u_{i_1}(\tau_1) u_{i_2}(\tau_2) \cdots u_{i_k}(\tau_k) \mathbb{U}(\tau_1 - \tau_2) \mathbb{U}(\tau_2 - \tau_3) \cdots \mathbb{U}(\tau_{k-1} - \tau_k)
$$

$$
d\tau_k d\tau_{k-1} \cdots d\tau_1,
$$

where U denotes the unit step function. Interchanging the order of integration gives

$$
E_{\eta}[u](t,0) = \int_0^t \int_{\tau_k}^t \cdots \int_{\tau_2}^t u_{i_1}(\tau_1) u_{i_2}(\tau_2) \cdots u_{i_k}(\tau_k) d\tau_1 d\tau_2 \cdots d\tau_k.
$$

Finally, substituting $t - \tau_1$ for τ_1 followed by $t - \tau_2$ for τ_2 , etc., yields the desired result, namely,

$$
E_{\eta}[u](t,0) = \int_0^t \int_0^{\tau_k} \cdots \int_0^{\tau_2} (u_{i_1}(t-\tau_1))(u_{i_2}(t-\tau_2)) \cdots (u_{i_k}(t-\tau_k)) d\tau_1 d\tau_2 \cdots d\tau_k
$$

= $E_{\tilde{\eta}}[u_t](t,0).$

The following theorem is immediate.

Theorem 3.1. If $c \in \mathbb{R}_{LC} \langle \langle X \rangle \rangle$ is coefficient reversible, then F_c is input reversible.

Definition 3.3. A word $\eta \in X^*$ is a palindrome if $\tilde{\eta} = \eta$. A series $c \in \mathbb{R} \langle \langle X \rangle \rangle$ is **palin**dromic if every word in its support is a palindrome.

In addition, c is even palindromic when it is palindromic and every word in its support has even length. Likewise, c is odd palindromic if it is palindromic and every word in its support has odd length.

Example 3.2. The polynomial $c = x_1x_0 + x_0x_1$ is coefficient reversible but not palindromic, while $d = x_0 x_1 x_0$ is coefficient reversible and odd palindromic. \Box

Lemma 3.3. A palindromic series c is coefficient reversible.

Proof: If c is palindromic, then

$$
\tilde{c} = \sum_{\eta \in X^*} (c, \eta)\tilde{\eta} = \sum_{\eta \in \text{supp}(c)} (c, \eta)\eta = \sum_{\eta \in X^*} (c, \eta)\eta = c.
$$

Hence, from Lemma [3.1,](#page-6-1) c is coefficient reversible.

For any $x_i \in X$ and $\eta \in X^*$, let $|\eta|_{x_i}$ denote the number of times the letter x_i appears in the word η .

Definition 3.4. [Fliess](#page-23-9) [\(1974,](#page-23-9) [1981\)](#page-23-7) A series $c \in \mathbb{R} \langle \langle X \rangle \rangle$ is said to be **exchangeable** if for all $i \in \{0, 1, \ldots, m\}$ and $\eta, \xi \in X^*$:

$$
|\eta|_{x_i} = |\xi|_{x_i} \Rightarrow (c, \eta) = (c, \xi).
$$

Example 3.3. The polynomial $c = x_1x_0 + x_0x_1$ is exchangeable and coefficient reversible, while $d = x_0 x_1 x_0$ is coefficient reversible but not exchangeable. \Box

Lemma 3.4. An exchangeable series c is coefficient reversible.

Proof: Given any $\eta \in X^*$ it follows that $|\eta|_{x_i} = |\tilde{\eta}|_{x_i}$ for all $i \in \{0, 1, ..., m\}$. If c is exchangeable, then $(c, \eta) = (c, \tilde{\eta})$. Hence, c is coefficient reversible.

Example 3.4. The series $c = x_1x_0 + x_0x_1$ is exchangeable but not palindromic. The series $d = x_0 x_1 x_0$ is palindromic but not exchangeable. The series

(5)
$$
e = (e, \emptyset)\emptyset + \sum_{j=1}^{\infty} (e, x_{i_j}^j) x_{i_j}^j,
$$

where $i_j \in \{0, 1, \ldots, m\}$, is both palindromic and exchangeable.

A series $c \in \mathbb{R}_{LC} \langle \langle X \rangle \rangle$ is exchangeable if only if F_c is an analytic function of E_{x_i} , $i =$ $0, 1, \ldots, m$ [\(Fliess, 1981,](#page-23-7) Proposition II.9). This implies that $y = F_c[u]$ has a state space realization of the form $\dot{z}_i = u_i, z_i(0) = 0, i = 0, 1, \ldots, m$, and $y = h(z)$ with h being real analytic about the origin. Therefore, c has Lie rank $\rho_L(c) \leq m+1$. The following class of exchangeable generating series were used by [Thitsa & Gray \(2012\)](#page-25-10) to define the notion of radius of convergence for the class of series whose minimum growth rate is parameterized by K, M in the sense of [\(2\)](#page-4-2) or [\(3\)](#page-4-3) (with $s = 0$).

Definition 3.5. A series $c \in \mathbb{R}_{LC} \langle \langle X \rangle \rangle$ is said to be **locally maximal** with growth constants $K, M > 0$ if $(c, \eta) = KM^{|\eta|}|\eta|!$, $\forall \eta \in X^*$. Likewise, a series $c \in \mathbb{R}_{GC} \langle \langle X \rangle \rangle$ is said to be **globally maximal** with growth constants $K, M > 0$ if $(c, \eta) = KM^{|\eta|}, \forall \eta \in X^*$.

Example 3.5. The assertion is that maximal series always have Lie rank equal to one. But first observe that the realization of Fliess provides a realization of $y = F_c[u]$ when c is a locally maximal series. Assume $X = \{x_0, x_1, \ldots, x_m\}$ and set $\dot{z}_i = u_i, z_i(0) = 0, i = 0, 1, \ldots, m$ with $h(z_1, z_2, \ldots, z_m) = K/(1 - Mz_1 - Mz_2 - \cdots - Mz_m)$. Then if follows that

$$
y = \frac{K}{1 - M \sum_{i=0}^{m} E_{x_i}[u]}
$$

= $K \sum_{k=0}^{\infty} M^k F_{\text{char}(X)}^k[u]$
= $K \sum_{k=0}^{\infty} M^k F_{(\text{char}(X))} \perp \mathbf{k}[u],$

where char(X) := $\sum_{i=0}^{m} x_i$ is the characteristic series of X, and $d^{\perp k}$ denotes the shuffle power of $d \in \mathbb{R}\langle\langle X\rangle\rangle$ [\(Fliess, 1981\)](#page-23-7). Next apply the identity $(\text{char}(X))^{\perp \perp k} = k!(\text{char}(X))^k$ and the fact that $(\text{char}(X))^k = \sum_{\eta \in X^k} \eta$, where X^k is the set of all words in X^* of length k.

 \Box

Figure 1. Relationship between the classes of symmetric formal power series $CR(X), P(X)$ and $E(X)$.

In which case,

$$
y = K \sum_{k=0}^{\infty} M^k k! F_{(\text{char}(X))^k}[u]
$$

=
$$
\sum_{k=0}^{\infty} \sum_{\eta \in X^k} KM^k k! E_{\eta}[u]
$$

=
$$
\sum_{\eta \in X^*} KM^{|\eta|} |\eta|! E_{\eta}[u].
$$

Therefore, $c = \sum_{\eta \in X} KM^{|\eta|} |\eta|! \eta$ as claimed. In particular, note that this realization is not minimal since the realization

$$
\dot{z} = 1 + \sum_{i=1}^{m} u_i, \ z(0) = 0, \ y = \frac{K}{1 - Mz}
$$

yields the same locally maximal generating series. That is, $\rho_L(c) = 1$. A similar calculation holds for the globally maximal case, but instead yields the minimal realization

$$
\dot{z} = 1 + \sum_{i=1}^{m} u_i, \ z(0) = 0, \ y = Ke^{Mz}.
$$

Let $CR(X)$, $P(X)$ and $E(X)$ be the subsets of $\mathbb{R}\langle\langle X\rangle\rangle$ consisting of all coefficient reversible series, palindromic series, and exchangeable series, respectively. The relationship between these three notions of symmetry for a formal power series is summarized in Figure [1.](#page-9-0) The intersection between palindromic and exchangeable series is described in the following theorem.

Theorem 3.2. A series $e \in P(X) \cap E(X)$ if and only if e has the form [\(5\)](#page-8-1).

Proof: The only nontrivial claim is that if series $e \in P(X) \cap E(X)$, then it must have the form [\(5\)](#page-8-1). The proof is by contradiction. Let $e \in P(X) \cap E(X)$ with at least one word $\eta = x_{i_1} x_{i_2} \cdots x_{i_j}$ in its support of length $j \ge 2$ (otherwise the claim is immediate). If $\eta \neq x_i^j$ i_j for some $x_{i_j} \in X$, then it contains at least two distinct letters $x_{i_j} \neq x_{i_k}$. Since the series

is exchangeable $(e, x_{ij} \eta' x_{i_k}) \neq 0$ for some $\eta' \in X^*$. But $x_{ij} \eta' x_{i_k} \in \text{supp}(e)$ implies that e cannot be palindromic, a contradiction. So e must have the form of [\(5\)](#page-8-1).

Example 3.6. Suppose $X = \{x_0, x_1\}$. A single-input, single-output (SISO) linear timeinvariant system is characterized by an impulse response of the form

$$
h(t) = \sum_{n=0}^{\infty} h_n \frac{t^n}{n!}.
$$

Repeated application of integration by parts gives

$$
y(t) = \int_0^t h(t - \tau)u(\tau) d\tau
$$

=
$$
\sum_{n=0}^{\infty} h_n \int_0^t \frac{(t - \tau)^n}{n!} u(\tau) d\tau
$$

=
$$
\sum_{n=0}^{\infty} h_n E_{x_0^n x_1}[u](t)
$$

=
$$
F_c[u](t),
$$

where the generating series is $c = \sum_{n\geq 0} h_n x_0^n x_1$. In general, a series $c \in \mathbb{R} \langle \langle X \rangle \rangle$ is said to be *linear* when every word in its support has exactly one instance of the letter $x_j \in X/\{x_0\}$ (recall $u_0 := 1$). In the present context, $\tilde{c} \neq c$. So linear time-invariant systems, in particular, lack all forms of symmetry described above. On the other hand, linear series whose support contains words of the form $x_0^i x_j x_0^k$ correspond to linear time-varying systems and can exhibit some forms of symmetry. A particular case is addressed in the next section. \Box

4. Globally maximal palindromic SISO linear systems

A palindromic SISO linear system always has an odd palindromic generating series of the form

$$
c = \sum_{n=0}^{\infty} (c, x_0^n x_1 x_0^n) x_0^n x_1 x_0^n.
$$

It is said be locally maximal when it has the form

(6)
$$
c = \sum_{n=0}^{\infty} KM^{2n}(2n)! x_0^n x_1 x_0^n
$$

and globally maximal when

(7)
$$
c = \sum_{n=0}^{\infty} KM^{2n} x_0^n x_1 x_0^n.
$$

(For convenience, the constants K and M in Definition [3.5](#page-8-0) have been redefined here using the fact that $(c, x_0^n x_1 x_0^n) = KM^{2n+1} = (KM)M^{2n}$ and $(c, x_0^n x_1 x_0^n) = KM^{2n+1}(2n+1)!$ $(KM)M^{2n}(2n)!(2n+1) \leq (KM)(2M)^{2n}(2n)!$. A Fliess operator F_c is called palindromic

when c is palindromic. In this section, three problems are addressed concerning globally maximal palindromic SISO linear systems. First, it is shown that such systems do not have finite Hankel rank or finite Lie rank. Thus, F_c does not have a finite dimensional bilinear or control affine state space realization. Next, an explicit form of the system's impulse response is derived from which it is possible to identify an infinite dimensional state space realization. Finally, the realization's zero dynamics are described.

4.1. **Nonexistence of finite dimensional realizations.** The series [\(7\)](#page-10-2) is R-algebraic since it satisfies the single polynomial equation

$$
c = Kx_1 + M^2x_0cx_0.
$$

But the first theorem asserts that c is not rational since its Hankel rank is infinite. The argument is a minor variation of one given by [Stanley \(1999,](#page-25-17) p. 283) for a similar type of series.

Theorem 4.1. The series $c = \sum_{n\geq 0} KM^{2n} x_0^n x_1 x_0^n$ has infinite Hankel rank.

Proof: If c had finite Hankel rank n, then it would have a linear representation (N_0, N_1, C, z_0) of dimension n. From the Cayley–Hamilton theorem, it would follow that for some set of real numbers a_i , $i = 1, 2, \ldots, n$

$$
KM^{2n} = (c, x_0^n x_1 x_0^n) = CN_0^n N_1 N_0^n z_0
$$

= $C(a_1 N_0^{n-1} + a_2 N_0^{n-2} + \dots + a_n I) N_1 N_0^n z_0$
= $a_1(c, x_0^{n-1} x_1 x_0^n) + a_2(c, x_0^{n-2} x_1 x_0^n) + \dots + a_n(c, x_1 x_0^n)$
= 0,

a contradiction. Thus, the Hankel rank of c is not finite.

The fact that the Hankel rank of c is infinite does not rule out the possibility that c could have a finite Lie rank, i.e., that c is a differentially generated series. But this turns out also not to be the case.

Theorem 4.2. The series $c = \sum_{n\geq 0} KM^{2n} x_0^n x_1 x_0^n$ has infinite Lie rank.

Proof: Define the family of polynomials $p_i = \text{ad}_{x_0}^i(x_1), i = 0, 1, \ldots$ in the free Lie algebra $\mathcal{L}(X)$ using the bracket operation $[x_0, x_1] := x_0 x_1 - x_1 x_0$, where $\text{ad}_{x_0}^0(x_1) = x_1$, and

$$
\mathrm{ad}_{x_0}^{i+1}(x_1) = [x_0, \mathrm{ad}_{x_0}^{i}(x_1)], \ i \ge 0.
$$

It is easily verified by induction that

$$
p_i = \sum_{k=0}^i \binom{i}{k} x_0^{i-k} x_1(-x_0)^k, \ \ i \ge 0,
$$

so that for any $\eta \in X^*$

(8)
$$
(p_i, \eta) = \sum_{k=0}^i {i \choose k} (-1)^k (x_0^{i-k} x_1 x_0^k, \eta).
$$

Given any $\xi \in X^*$, it follows from the linearity of \mathcal{H}_c that

$$
(\mathcal{H}_c(p_i), \xi) = \sum_{\eta \in X^*} (\mathcal{H}_c(\eta), \xi)(p_i, \eta)
$$

$$
= \sum_{\eta \in X^*} (c, \xi \eta)(p_i, \eta).
$$

Setting $\xi = x_0^j$ $_0^j$ and substituting [\(8\)](#page-11-1) gives

$$
(\mathcal{H}_c(p_i), x_0^j) = \sum_{\eta \in X^*} \sum_{k=0}^i (c, x_0^j \eta) {i \choose k} (-1)^k (x_0^{i-k} x_1 x_0^k, \eta)
$$

=
$$
\sum_{k=0}^i (c, x_0^{i+j-k} x_1 x_0^k) {i \choose k} (-1)^k
$$

=
$$
\begin{cases} KM^{2k} {i \choose k} (-1)^k & : 2k = i + j, \ j \le i \\ 0 & : \text{otherwise.} \end{cases}
$$

Thus, every $\mathcal{H}_c(p_i)$ is a polynomial in $\mathbb{R}[X_0]$, where $X_0 = \{x_0\}$. For example,

$$
\mathcal{H}_c(p_0) = K
$$

\n
$$
\mathcal{H}_c(p_1) = -KM^2x_0
$$

\n
$$
\mathcal{H}_c(p_2) = -2KM^2 + KM^4x_0^2
$$

\n
$$
\mathcal{H}_c(p_3) = 3KM^4x_0 - KM^6x_0^3
$$

\n
$$
\vdots
$$

In particular, for any $i \geq 0$, $(\mathcal{H}_c(p_i), x_0^i) = KM^{2i}(-1)^i \neq 0$. Therefore, $\mathcal{H}_c(p_i)$ is a polynomial of degree *i*. Let S_p denote the subspace of $\mathcal{L}(X)$ spanned by the p_i 's. Necessarily, $\dim(\mathcal{H}_c(S_p)) \leq \dim(\mathcal{H}_c(\mathcal{L}(X))).$ But $\mathcal{H}_c(S_p)$ is not a finite dimensional subspace of $\mathbb{R}[X_0].$ Thus, $\mathcal{H}_c(\mathcal{L}(X))$ cannot be finite dimensional. \blacksquare

4.2. An infinite dimensional realization. The palindromic system $y = F_c[u]$, where c is given by [\(7\)](#page-10-2) can be written in the form

$$
y(t) = \int_0^t h(t, \tau) u(\tau) d\tau,
$$

where the impulse response is

(9)
$$
h(t,\tau) = K \sum_{n=0}^{\infty} M^{2n} \frac{(t-\tau)^n}{n!} \frac{\tau^n}{n!}
$$

for $t \geq \tau \geq 0$. Observe that [\(9\)](#page-12-1) can be written in the form

(10)
$$
h(t,\tau) = K \sum_{n=0}^{\infty} \frac{(Mt)^n}{n!} J_n(2M\tau),
$$

FIGURE 2. Plot of $h(t, \tau)$ versus τ for $t = 1, 2, 3$ and $K = M = 1$ in the globally maximal case

where

(11)
$$
J_n(\tau) = \sum_{k=0}^{\infty} \frac{(-1)^k}{k!(n+k)!} \left(\frac{\tau}{2}\right)^{n+2k}
$$

is the *n*-th order Bessel function of the first kind. Thus, the input-output map is

(12)
$$
y(t) = K \sum_{n=0}^{\infty} \frac{(Mt)^n}{n!} \int_0^t J_n(2M\tau) u(\tau) d\tau.
$$

Using the Bessel function multiplication identity,

$$
J_0(\lambda z) = \sum_{n=0}^{\infty} \frac{1}{n!} \left(\frac{(1 - \lambda^2)z}{2} \right)^n J_n(z), \ \ \forall z, \lambda \in \mathbb{C}
$$

(e.g., see [Truesdell \(1950\)](#page-25-18)), equation [\(10\)](#page-12-2) simplifies to

$$
h(t,\tau) = KJ_0(2iM\sqrt{(t-\tau)\tau}) = KI_0(2M\sqrt{(t-\tau)\tau}),
$$

where $I_0(z)$ denotes the zeroth order modified Bessel function of the first kind (see Fig-ure [2\)](#page-13-0). From [\(12\)](#page-13-1) it follows directly that F_c has the infinite dimensional, linear time-varying realization

(13a)
$$
\dot{z}(t) = B(t)u(t), \ \ z(0) = 0
$$

(13b)
$$
y(t) = C(t)z(t)
$$

with $z = [z_0 \ z_1 \ z_2 \cdots]^T$, $B = [B_0 \ B_1 \ B_2 \cdots]^T$, and $C=[C_0 \ C_1 \ C_2 \cdots]$, where $z_n(t)$ $\int_0^t J_n(2M\tau)u(\tau) d\tau$, $B_n(t) = J_n(2Mt)$, and $C_n(t) = K(Mt)^n/n!$.

Next, observe that

$$
\dot{y}(t) = KM \sum_{n=0}^{\infty} \frac{(Mt)^n}{n!} z_{n+1}(t) + \left(K \sum_{n=0}^{\infty} \frac{(Mt)^n}{n!} J_n(2Mt)\right) u(t).
$$

Since $J_0(0) = 1$, it follows that system [\(13\)](#page-13-2) has relative degree $r = 1$ at every point $z_0 \in \mathbb{R}^{\infty}$. Thus, if it is initialized at any $z(0)$ whose first component $z_0(0) = 0$, then this system has zero dynamics of the form

(14)
$$
\dot{z}_n^* = J_n(2Mt)u^*(t), \ \ z_n^*(0) = \frac{z_{0,n}}{n!}, \ \ n \ge 1,
$$

where

$$
u^*(t) = -\frac{M \sum_{n=0}^{\infty} \frac{(Mt)^n}{n!} z_{n+1}^*(t)}{\sum_{n=0}^{\infty} \frac{(Mt)^n}{n!} J_n(2Mt)}.
$$

A more explicit expression for these dynamics is developed in the next section.

4.3. Zero dynamics. Consider first the general problem of selecting an input u^* such that the output $y = F_c[u^*]$ is exactly the zero function on an interval $[0, T]$ over which the series converges. In the SISO case where $X = \{x_0, x_1\}$, the generating series $c \in \mathbb{R}\langle\langle X\rangle\rangle$ can be partitioned into its natural part $c_N = \sum_{k\geq 0} (c, x_0^k) x_0^k$ and its forced part $c_F = c - c_N$. Note that every word in the support of c_N is a palindrome. Let $r \geq 1$ be the largest integer such that supp $(c_F) \subset x_0^{r-1} X^*$. Then c is said to have *relative degree* r if the word $x_0^{r-1} x_1$ is also in the support of c_F . Otherwise, c does not have relative degree [\(Gray, et al., 2014\)](#page-23-13). This notion is consistent with the state space definition of relative degree when F_c has a controlaffine realization. The series c is said to be *primely nullable* when there exists a unique input u^{*} such that the output $y = F_c[u^*]$ is zero on some interval [0, T]. A sufficient condition for c to be primely nullable is having relative degree r and $\text{supp}(c_N) \subseteq x_0^r X_0^*$ being nonempty [\(Gray, et al., 2024,](#page-24-17) Theorem 3.1).

Consider now the case where $c_F = \sum_{n\geq 0} KM^{2n} x_0^n x_1 x_0^n$, which has relative degree one as expected. The series $c = c_N + c_F$ is then primely nullable for any $c_N = \sum_{k \geq 1} (c, x_0^k) x_0^k$. The following theorem is essential.

Theorem 4.3. Let $c_N = \sum_{k\geq 1} (c, x_0^k) x_0^k$ be a globally convergent series. The palindromic series $c = c_N + \sum_{n\geq 0} KM^{2n} x_0^{\overline{n}} x_1 x_0^n$ satisfies $F_c[u^*]=0$ on any finite interval $[0,T]$, where tu[∗] (t) has the Neumann series in terms of Bessel functions

$$
tu^{*}(t) = \sum_{k=1}^{\infty} -(c, x_0^{k}) \frac{k}{KM^{k}} J_{k}(2Mt),
$$

or equivalently,

(15)
$$
u^*(t) = \sum_{k=1}^{\infty} (c, x_0^k) u_k^*(t),
$$

where $u_k^*(t) := -kJ_k(2Mt)/(KM^kt)$.

The first three u_k^* are shown in Figure [3](#page-15-0) when $K = M = 1$. For the simplest case where $c_N = x_0$, the numerically computed output $y(t)$ is equivalent to machine zero for all $t \geq 0$ as shown in Figure [4.](#page-15-1) In fact, this is the case for *every* simulated output $F_{x_0^k+c_F}[u_k^*], k \ge 1$. This motivates the following lemma from which the proof of the theorem follows directly from superposition.

FIGURE 3. Input $u_k^*(t) = -kJ_k(2t)/t$, $k = 1, 2, 3$

FIGURE 4. Simulated output $y = F_{x_0 + c_F}[u_1^*]$ when $K = M = 1$

Lemma 4.1. Fix real number $M > 0$. For any integer $k \geq 1$,

$$
\frac{(Mt)^k}{k!} - \int_0^t I_0(2M\sqrt{(t-\tau)\tau}) \frac{k}{\tau} J_k(2M\tau) d\tau = 0, \ \ t \ge 0.
$$

Proof: The series expansions (11) and

(16)
$$
I_0(z) = \sum_{i=0}^{\infty} \frac{1}{(i!)^2} \left(\frac{z}{2}\right)^{2i}
$$

are first applied to yield a series expansion for the integral

$$
\int_0^t I_0(2M\sqrt{(t-\tau)\tau})\frac{1}{M\tau}J_k(2M\tau) d\tau
$$

=
$$
\sum_{i,j=0}^\infty \frac{(-1)^j M^{2i+2j+k}}{(i!)^2 j!(j+k)!} \int_0^t (t-\tau)^i \tau^{i+2j+k-1} d\tau.
$$

The change of variables $\tau = t\tau'$ yields the expression

$$
\int_0^t I_0(2\sqrt{(t-\tau)\tau}) \frac{1}{\tau} J_k(2\tau) d\tau
$$

=
$$
\left[\sum_{i,j=0}^\infty \frac{(-1)^j (Mt)^{2i+2j}}{(i!)^2 j! (j+k)!} B(i+2j+k, i+1) \right] (Mt)^k,
$$

where

$$
B(z_1, z_2) = \int_0^1 \tau^{z_1 - 1} (1 - \tau)^{z_2 - 1} d\tau
$$

is the beta function. From the identity

$$
B(m, n) = \frac{(m-1)!(n-1)!}{(m+n-1)!}, \forall m, n \in \mathbb{N},
$$

it follows that the term in the square brackets above is

$$
\sum_{i,j=0}^{\infty} (-1)^j \frac{(i+2j+k-1)!}{i!j!(j+k)!(2i+2j+k)!} (Mt)^{2i+2j}.
$$

The assertion is that this infinite sum is equal to $1/(k(k))$ for all $k \geq 1$ and does not depend on the value of M or t . The proof is technical. It can be found in Appendix A. Using this identity, the theorem is proved. П

Returning to the problem of determining the zero dynamics, combining [\(14\)](#page-14-1) and [\(15\)](#page-14-2) yields for $n \geq 1$

$$
\dot{z}_n^*(t) = -J_n(2Mt) \sum_{k=1}^{\infty} (c, x_0^k) \frac{k J_k(2Mt)}{KM^k t}, \ \ t \ge 0
$$

with $z_n(0) = (c, x_0^n)/n!$.

Example 4.1. Suppose $c_N = \sum_{k \ge 1} (-1)^{k+1} 2k x_0^{2k}$ and $c_F = \sum_{n \ge 0} x_0^n x_1 x_0^n$. Then

$$
F_{c_N}[u](t) = \sum_{k=1}^{\infty} (-1)^{k+1} 2k \frac{t^{2k}}{(2k)!} = 2t \sin(t), \ \ t \ge 0
$$

and

$$
u^*(t) = \sum_{k=1}^{\infty} (-1)^{k+1} 2k \left(-\frac{2k}{t} J_{2k}(2t) \right)
$$

= $-\sin(2t), t \ge 0$

using the known identity

$$
\sum_{k=1}^{\infty} (-1)^{k+1} (2k)^2 J_{2k}(z) = \frac{z \sin(z)}{2}
$$

[\(Gradshteyn & Ryzhik, 1980,](#page-23-14) p. 974). Again, a numerical simulation shows that $y(t)$ is equivalent to machine zero for all $t \geq 0$. The zero dynamics must satisfy

$$
\dot{z}_n^*(t) = J_n(2t)\sin(2t), \ \ t \ge 0.
$$

with $z_n(0) = 0$ for $n \ge 1$ odd and $z_n(0) = -(-1)^{n/2}/(n-1)!$ for $n \ge 2$ even. It is not difficult to show that none of these states are bounded as t goes to infinity. So the system's zero dynamics are not stable in any sense. \Box

5. Locally maximal palindromic SISO linear systems

In this section, the same three problem from the previous section are addressed except now for locally maximal palindromic SISO linear systems. The main difference is that here the impulse response has a singularity, and the radius of convergence of the Fliess operator is finite.

5.1. Nonexistence of finite dimensional realizations. The first theorem rules out the possibility that locally maximal palindromic linear systems are rational, i.e., have finite Hankel rank.

Theorem 5.1. The series $c = \sum_{n\geq 0} KM^{2n}(2n)! x_0^n x_1 x_0^n$ has infinite Hankel rank.

Proof: The proof is by contradiction. If c had finite Hankel rank, then it would have a linear representation (C, N_0, N_1, z_0) so that [\(4\)](#page-5-1) is satisfied. This would imply that

$$
|(c, x_{i_k} \cdots x_{i_1})| = |CN_{i_k} \cdots N_{i_i} z_0|.
$$

Applying the Cauchy-Schwarz inequality and using any submultiplicative matrix norm, it would then follow that

$$
|(c, x_{i_k} \cdots x_{i_1})| \leq ||C|| \, ||N_{i_k}|| \cdots ||N_{i_i}|| \, ||z_0|| \leq KM^k,
$$

where $K = ||C|| ||z_0||$ and $M = \max(||N_0||, ||N_1||)$. This is clearly a contradiction as the coefficients of c are growing at a factorial rate.

It is conjectured that c above is also not algebraic for the same reason that the coefficients are growing faster than what a proper R-algebraic system can produce. A precise argument would require using the representation theory of Shamir for algebraic series [\(Petre & Salomaa,](#page-25-16) [2009;](#page-25-16) [Shamir, 1967\)](#page-25-15), but that issue is beyond the scope of the present work. The next theorem is the local version of Theorem [4.2,](#page-11-2) which again eliminates the possibility of a control-affine realization.

Theorem 5.2. The series $c = \sum_{n\geq 0} KM^{2n}(2n)! x_0^n x_1 x_0^n$ has infinite Lie rank.

Proof: The same proof for Theorem [4.2](#page-11-2) applies in this case.

5.2. An infinite dimensional realization. The impulse response for [\(6\)](#page-10-3) is computed directly from [\(9\)](#page-12-1) by introducing the factorial term $(2n)!$ from the coefficients, that is, for $t \geq \tau \geq 0$

$$
h(t,\tau) = K \sum_{n=0}^{\infty} \frac{(2n)!}{n!} (M^2 t)^n J_n(2M\tau)
$$

FIGURE 5. Plot of $h(1, \tau)$ versus τ for $K = 1$ and various M in the locally maximal case

$$
(17) \qquad \qquad = \frac{K}{\sqrt{1 - 4M^2(t - \tau)}\tau},
$$

which has two distinct real singularities whenever $Mt > 1$, namely at $\tau_{\pm} = (t \pm p(t))/2$ with $p(t) := \sqrt{(Mt)^2 - 1}/M$ (see Figure [5\)](#page-18-0). For the case where $Mt < 1$, the presence of complex singularities τ_{\pm} will bound the radius of convergence of the Taylor series of $h(t, \cdot)$ about $\tau = 0$ by $|\tau_{\pm}|$. The corresponding state space model is the same as that given in [\(13\)](#page-13-2) except now $C_n(t) = K(MT)^n(2n)!/n!$, $n \in \mathbb{N}_0$. Therefore, this realization also has relative degree $r = 1$ and its zero dynamics are still given by [\(14\)](#page-14-1) except that u^* has to be recomputed as presented in the next section.

5.3. Zero dynamics. Given two vectors $a \in \mathbb{R}^p$ and $b \in \mathbb{R}^q$, the generalized hypergeometric function

$$
{}_{p}F_{q}(a;b;z) = \sum_{k=0}^{\infty} \frac{(a_{1})_{k} \cdots (a_{p})_{k}}{(b_{1})_{k} \cdots (b_{q})_{k}} \frac{z^{k}}{k!}
$$

is defined on the complex plane C with $(x)_k := \Gamma(x+k)/\Gamma(x)$ being the Pochhammer symbol, and Γ is the gamma function [\(Askey & Olde Daalhuis, 2010\)](#page-23-15). In general, $_{q+1}F_q(a;b;z)$ is a multi-valued function with a branch cut discontinuity in the complex plane running from $-\infty$ to -1 and from 1 to ∞ . It will be assumed here that such functions are defined in terms of their principal values when $z \in [0, 1)$. In light of [\(11\)](#page-13-3) and [\(16\)](#page-15-2), it is not difficult to show that for any nonnegative real number α :

$$
J_{\alpha}(x) = {}_0F_1 \left(; \alpha + 1; -\frac{1}{4}x^2 \right) \frac{\left(\frac{x}{2}\right)^{\alpha}}{\Gamma(\alpha+1)}
$$

$$
I_{\alpha}(x) = {}_0F_1 \left(; \alpha + 1; \frac{1}{4}x^2 \right) \frac{\left(\frac{x}{2}\right)^{\alpha}}{\Gamma(\alpha+1)}.
$$

The function ${}_0F_1(;a;z)$ is a limiting case usually referred to as a *confluent hypergeometric* function. Given these identities and Theorem [4.3,](#page-14-3) the following theorem is not entirely unexpected.

Theorem 5.3. Let $c_N = \sum_{k \geq 1} (c, x_0^k) x_0^k$ be a locally convergent series so that $y_N = F_{c_N}[u]$ converges on [0, T_N]. Given the palindromic series $c_F = \sum_{n\geq 0} KM^{2n}(2n)! x_0^n x_1 x_0^n$, define

$$
f_j^e(t) = K_3 F_2(a_j^e; b_j^e; (Mt)^2) \frac{t^{1+2j}}{1+2j}, \quad j \ge 0
$$

$$
f_0^o(t) = K_2 F_1(a_0^o; b_0^o; (Mt)^2) \frac{t^2}{2}
$$

$$
f_j^o(t) = K_3 F_2(a_j^o; b_j^o; (Mt)^2) \frac{t^{2+2j}}{2+2j}, \quad j \ge 1,
$$

where

$$
\begin{aligned} a_j^e &= \left[\frac{1}{2},\ 1,\ 1+2j\right],\ \ b_j^e &= \left[1+j,\ \frac{3}{2}+j\right],\ \ j\geq 0\\ a_0^o &= \left[1,\frac{1}{2}\right],\ \ b_0^o &= \left[\frac{3}{2}\right] \\ a_j^o &= \left[\frac{1}{2},\ 1,\ 2+2j\right],\ \ b_j^o &= \left[\frac{3}{2}+j,\ 2+j\right],\ \ j\geq 1. \end{aligned}
$$

If $MT < 1$, and u^* is a power series whose coefficients $u_j^*, j \geq 0$ satisfy

(18)
$$
y_N(t) + \sum_{j=0}^{\infty} u_{2j}^* f_j^e(t) + u_{2j+1}^* f_j^o(t) = 0,
$$

then $y = F_c[u^*] = 0$ on $[0, \min(T_N, T)].$

Proof: A straightforward calculation gives for $j \geq 0$

$$
\int_0^t h(t,\tau)\tau^{2j} d\tau = \sum_{n=j}^\infty \frac{(2(n-j))!(n+j)!}{(n-j)!} M^{2(n-j)} \frac{t^{1+2n}}{(1+2n)!}
$$

$$
= K_3 F_2(a_j^e; b_j^e; (Mt)^2) \frac{t^{1+2j}}{1+2j},
$$

where h is given by [\(17\)](#page-18-2) and $t \in [0, T]$ with $MT < 1$. Likewise,

$$
\int_0^t h(t,\tau)\tau \,d\tau = \sum_{n=0}^\infty \frac{(2n)!}{(2n+1)!} M^{2n} \frac{t^{2n+2}}{2}
$$

$$
= K_2 F_1(a_0^o; b_0^o; (Mt)^2) \frac{t^2}{2}
$$

and

$$
\int_0^t h(t,\tau)\tau^{1+2j} d\tau = \sum_{n=j}^\infty \frac{(2(n-j))!(n+j+1)!}{(n-j)!(n+1)} M^{2(n-j)} \frac{t^{2+2n}}{2(1+2n)!}
$$

= $K_3 F_2(a_j^o;b_j^o;(Mt)^2) \frac{t^{2+2j}}{2+2j}.$

FIGURE 6. Plot of y_N and $-y_F$ in Example [5.2](#page-21-3)

Setting $u^*(\tau) = \sum_{j=0}^{\infty} u_j^* \tau^j$, it then follows from linearity that the forced response is

$$
y_F(t) = \sum_{j=0}^{\infty} u_{2j}^* f_j^e(t) + u_{2j+1}^* f_j^o(t).
$$

If the coefficients are then selected to satisfy [\(18\)](#page-19-0), the system output is $y = y_N + y_F = 0$ on $[0, \min(T_N, T)]$ as desired.

Equation [\(18\)](#page-19-0) can be written in the form of a linear set of equations $Ax = b$ by equating the coefficients of like powers of t . In this case, A turns out to be lower triangular with no zeros along the diagonal. In contrast, Theorem [4.3](#page-14-3) for the global case corresponds to a system where A is diagonal, hence the more explicit expression (15) for u^* is possible. In the present context then the zero dynamics are given by

$$
\dot{z}_n^*(t) = J_n(2Mt) \sum_{k=0}^{\infty} u_k^*, \ \ t \ge 0
$$

with $z_n(0) = (c, x_0^n)/n!$, $n \ge 1$, and where the coefficients of u^* satisfy [\(18\)](#page-19-0). Of course, the input series yielding the zero output of the system only converges on a finite interval as described in Theorem [5.3.](#page-19-1)

Example 5.1. Consider a locally maximal palindromic linear system $c = c_F + c_N$, where

$$
c_F = \sum_{n\geq 0} KM^{2n}(2n)! x_0^n x_1 x_0^n
$$

$$
c_N = \sum_{k=1}^{\infty} M^{2k-1}(2(k-1))! x_0^{2k-1}.
$$

Here y_N is the odd function Arctanh (Mt) converging on [0, 1). This example is simple enough that [\(18\)](#page-19-0) can be solved directly to give $u^*(t) = -M/K$, $t \in [0,1)$. In which case, the zero dynamics are given by

$$
z_n^*(t) = -\frac{M}{K}J_n(2Mt), \ \ t \in [0,1)
$$

so that

$$
z_n(t) = z_n(0) - \frac{M}{K} \int_0^t J_n(2M\tau) d\tau
$$

= $\frac{M^n}{n} \delta_n^o - \frac{1}{K} {}_1F_2 \left(\left[\frac{1}{2} + \frac{n}{2} \right] ; \left[\frac{3}{2} + \frac{n}{2}, 1 + n \right] ; -(Mt)^2 \right) \frac{(Mt)^{1+n}}{(1+n)!},$

where $\delta_n^o = 1$ when n is odd and zero otherwise. Given the finite interval of convergence, a stability analysis of the zero dynamics is not possible. \Box

Example 5.2. Consider next the case of a locally maximal palindromic linear system with $K = 1, M = 1$, and $y_N(t) = e^t \sin(2\pi t)$. This function has a globally convergent generating series c_N which is neither even or odd, so the problem of computing u^* is more complex. It can be solved approximately by truncating [\(18\)](#page-19-0) to a degree 20 polynomial and then solving numerically. The Mathematica code to do this is given in Appendix B. Figure [6](#page-20-0) shows the output components y_N and $-y_F$, where the latter is computed numerically using [\(17\)](#page-18-2) in the convolution integral. Ideally, these components should match exactly so that $y = y_N + y_F = 0$. But the truncation error in y_F becomes apparent as t approaches the convergence boundary at $T = 1$. Here the zero dynamics can be determined numerically, but they do not have a simple expression as in the previous example. \Box

6. Conclusions

Two new notions of symmetry for Chen–Fliess input-output systems were given: coefficient reversible symmetry and palindromic symmetry. Each concept was then related to an existing type of symmetry described by exchangeable generating series. Next, a detailed analysis was given for globally and locally maximal palindromic SISO linear systems. In each case, it was shown that such generating series have an infinite Hankel rank and Lie rank, have a certain infinite dimensional state space realization, and a description of their relative degree and zero dynamics was given.

Appendix A. Combinatorial identity

Lemma A.1. For all $M, t \in \mathbb{R}$ and integers $k \geq 1$

$$
\sum_{i,j=0}^{\infty}(-1)^j\frac{(i+2j+k-1)!}{i!j!(j+k)!(2i+2j+k)!}(Mt)^{2i+2j}=\frac{1}{k(k!)}.
$$

Proof: Setting $\ell = i + j$ on the left-hand side gives

$$
\sum_{\ell=0}^{\infty} \left[\sum_{j=0}^{\ell} (-1)^j \frac{(\ell+j+k-1)!}{(\ell-j)!j!(j+k)!} \right] \frac{(Mt)^{2\ell}}{(2\ell+k)!}.
$$

The first term in the infinite series where $\ell = 0$ is $1/(k(k!)$. Thus, the claim is that

$$
\sum_{j=0}^{\ell} (-1)^j \frac{(\ell+j+k-1)!}{(\ell-j)!j!(j+k)!} = 0, \quad \forall \ell > 0,
$$

or equivalently,

$$
\sum_{j=0}^{\ell}(-1)^j {\ell+k+j-1 \choose j} {\ell+k \choose \ell-j} = 0, \quad \forall \ell > 0.
$$

From upper negation [\(Graham, et al., 1994,](#page-23-16) p. 164), it follows that

$$
(-1)^j \binom{\ell+k+j-1}{j} = \binom{-(\ell+k)}{j}.
$$

Therefore, using the Vandermonde convolution identity [\(Graham, et al., 1994,](#page-23-16) p. 174)

$$
\sum_{j=0}^{\ell} (-1)^j {\ell + k + j - 1 \choose j} {\ell + k \choose \ell - j}
$$

$$
= \sum_{j=0}^{\ell} {\binom{-(\ell + k)}{j}} {\ell + k \choose \ell - j}
$$

$$
= {\binom{0}{\ell}} = 0
$$

as claimed when $\ell > 0$.

APPENDIX B. CODE TO COMPUTE u^* : LOCALLY MAXIMAL CASE

The following Mathematica (v12) code was used to compute an estimate of u^* using [\(18\)](#page-19-0) with the upper bound truncated to $J = 10$ and where $y_N(t) = e^t \sin(2\pi t)$.

```
K=1; M=1;J=10;
aej = {1/2, 1, 1+2j}; bej = {1+j, 3/2+j};
fe[j_]=K HypergeometricPFQ[aej,bej,(M t)^2]
   t^*(1+2j)/(1+2j);ao0=\{1,1/2\};bo0=\{3/2\};fo0=K HypergeometricPFQ[ao0,bo0,(M t)^2] t^2/2;
aoj={1/2,1,2+2j}; boj={3/2+j,2+j};
fo[j_]=K HypergeometricPFQ[aoj,boj,(M t)^2]
   t^*(2+2j)/(2+2j);feSum=Sum[ustarcoef[2j]*fe[j],{j,0,J}];
foSum=Sum[ustarcoef[2j+1]*fo[j],{j,1,J}];
yN=Exp[t]Sin[2 Pi t];
```
 \blacksquare

```
sum=Series[yN+feSum+ustarcoef[1]fo0
   +foSum,{t,0,1+2J}];
sol=Solve[CoefficientList[sum,t]==0,
   Array[ustarcoef,1+2J,0]];
ustar[t_] = Sum[ustarcoef[j]*t^j, {j, 0, 2 J}]
   /. sol
