Abstract

In this paper, we investigate a specific class of q-polynomial sequences that serve as a q-analogue of the classical Appell sequences. This framework offers an elegant approach to revisiting classical results by Carlitz and, more interestingly, to establishing an important extension of the Carlitz q -Bernoulli polynomials and numbers. In addition, we establish explicit series representations for our extended Carlitz q-Bernoulli numbers and express them in terms of q-Stirling numbers of the second kind. This leads to a novel formula that explicitly connects the Carlitz q -Bernoulli numbers with the q -Stirling numbers of the second kind.

MSC 2020: Primary 05A30; Secondary 11B68, 11B73, 05A40.

Keywords: Carlitz q-Bernoulli numbers and polynomials, q-analogue of Appell sequences, q analogues of sums of consecutive powers of natural numbers, q-Stirling numbers of the second kind, umbral calculus.

1 Introduction and Notation

Throughout this paper, we let $\mathbb N$ and $\mathbb N_0$ respectively denote the set of positive integers and the set of nonnegative integers. For $n \in \mathbb{N}_0$, we let $(X)_n$ denote the *falling factorial* of X to depth n, defined as

$$
(X)_n := X(X - 1) \cdots (X - n + 1).
$$

The Stirling numbers of the second kind, denoted $S(n, k)$ $(n, k \in \mathbb{N}_0, n \geq k)$, are then defined through the polynomial identity:

$$
X^n = \sum_{k=0}^n S(n,k)(X)_k \qquad (\forall n \in \mathbb{N}_0).
$$

The Bernoulli polynomials are denoted, as usual, by $B_n(X)$ and the Bernoulli numbers by B_n ($n \in \mathbb{N}_0$). A modern definition of the Bernoulli polynomials and numbers employs their exponential generating functions, given by

$$
\frac{t}{e^t - 1} e^{Xt} = \sum_{n=0}^{\infty} B_n(X) \frac{t^n}{n!} , \frac{t}{e^t - 1} = \sum_{n=0}^{\infty} B_n \frac{t^n}{n!}
$$

(so $B_n = B_n(0)$ for all $n \in \mathbb{N}_0$). As is well-known, the Bernoulli polynomials and numbers play a central role in various branches of mathematics, including number theory, mathematical analysis, and algebraic geometry. For a modern and exhaustive perspective, the reader is referred to the paper by Kouba [\[7\]](#page-24-0). An interesting and well-known formula expressing the Bernoulli numbers in terms of the Stirling numbers of the second kind is given by:

$$
B_n = \sum_{k=0}^n (-1)^k \frac{k!}{k+1} S(n,k) \qquad (\forall n \in \mathbb{N}_0)
$$
 (1.1)

(see e.g., [\[4,](#page-24-1) Corollary 2.8]).

It should be noted that the Bernoulli polynomial sequence $(B_n(X))_{n\in\mathbb{N}_0}$ belongs to the broader class of Appell sequences (see [\[3,](#page-24-2) [9\]](#page-24-3)). These are sequences of polynomials $(P_n(X))_{n\in\mathbb{N}_0}$ characterized by the following properties: $P_0(X)$ is a nonzero constant polynomial, and for all $n \in \mathbb{N}$, the derivatives satisfy the relation $P'_n(X) = nP_{n-1}(X)$. Using the Taylor expansion, an Appell polynomial sequence $(P_n(X))_n$ can also be characterized by its general term, which takes the form

$$
P_n(X) = \sum_{k=0}^n \binom{n}{k} p_k X^{n-k} \qquad (\forall n \in \mathbb{N}_0),
$$

where $(p_k)_{k \in \mathbb{N}_0}$ is a sequence of scalars with $p_0 \neq 0$.

Further, let q be a positive real parameter. The q-analogue of X , whether treated as an indeterminate or a number, is defined by:

$$
[X] := \frac{q^X - 1}{q - 1}.
$$

For $k \in \mathbb{N}_0$, the q-analogue $[X]_k$ of $(X)_k$ is defined as

$$
[X]_k := [X] \cdot [X - 1] \cdots [X - k + 1].
$$

For $n \in \mathbb{N}_0$, the q-analogue of n! is given by

$$
[n]! := [n]_n = [n] \cdot [n-1] \cdots [1].
$$

Furthermore, for $n, k \in \mathbb{N}_0$ with $n \geq k$, the q-analogue $\begin{bmatrix} n \\ k \end{bmatrix}$ $\binom{n}{k}$ of the binomial coefficient $\binom{n}{k}$ $\binom{n}{k}$ is defined as

$$
\binom{n}{k} := \frac{[n]!}{[k]![n-k]!} = \frac{[n]_k}{[k]!}.
$$

These numbers appear, in particular, in the famous Gauss binomial formula:

$$
\prod_{k=0}^{n-1} (x + q^k y) = \sum_{k=0}^{n} q^{\frac{k(k-1)}{2}} {n \choose k} x^{n-k} y^k \qquad (\forall n \in \mathbb{N}, \forall x, y \in \mathbb{R}),
$$
\n(1.2)

and, just like the classical binomial coefficients, they also have a combinatorial interpretation (see, e.g., $[5]$).

On the other hand, we let Δ denote the forward difference operator which acts linearly on $\mathbb{R}[X]$ by the formula:

$$
(\Delta P)(X) := P(X+1) - P(X) \qquad (\forall P \in \mathbb{R}[X]).
$$

It is well known and easy to verify that the n-fold composition of Δ is given by the formula:

$$
(\Delta^n P)(X) = \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} P(X+k) \qquad (\forall P \in \mathbb{R}[X], \forall n \in \mathbb{N}_0). \tag{1.3}
$$

In this paper, we call a *q-polynomial* any polynomial in [X] with real coefficients. Equivalently, a q-polynomial is a polynomial in q^X with real coefficients. The degree of a q-polynomial refers to its degree as a polynomial in [X] (or equivalently in q^X). We denote by $\mathscr E$ the $\mathbb R$ vector space of all q-polynomials and by \mathscr{E}_d ($d \in \mathbb{N}_0$) the R-vector subspace of \mathscr{E} consisting of q-polynomials of degree $\leq d$. An important example of q-polynomials arises naturally in the evaluation of sums of the form

$$
S_{n,r}(N) := \sum_{k=0}^{N-1} q^{rk} [k]^n
$$

 $(N, n \in \mathbb{N}_0, r \in \mathbb{N})$, which are q-analogues of the sum of powers $\sum_{k=0}^{N-1} k^n$. More interestingly, when expressed as a linear combination of the q-polynomials $q^{kN} [N]^{n-k}$ $(0 \leq k \leq n)$, $S_{n,r}(N)$ leads to a q-analogue example of Appell polynomial sequences (see Theorem [2.6\)](#page-7-0). Perhaps it was by exploring this fact that Carlitz $[1]$ obtained important q-analogues of Bernoulli numbers and polynomials. By means of the symbolic calculus, Carlitz [\[1\]](#page-23-0) defined two real sequences $(\eta_n)_{n \in \mathbb{N}_0}$ and $(\beta_n)_{n \in \mathbb{N}_0}$ (depending on q) by:

$$
\begin{cases}\n\eta_0 = 1, \eta_1 = 0, \\
(q\eta + 1)^n = \eta^n \quad (\forall n \ge 2)\n\end{cases},
$$
\n(1.4)

$$
\begin{cases}\n\beta_0 = 1, \\
q(q\beta + 1)^n - \beta^n = \delta_{n,1} \quad (\forall n \in \mathbb{N})\n\end{cases},
$$
\n(1.5)

where $\delta_{i,j}$ denotes the Kronecker delta. Furthermore, it is noted that for all $n \in \mathbb{N}_0$:

$$
\beta_n = \eta_n + (q-1)\eta_{n+1}.\tag{1.6}
$$

Although both sequences are intriguing, the sequence $(\beta_n)_n$ is particularly noteworthy because its terms are well-defined at $q = 1$ (unlike $(\eta_n)_n$, for which only the first two terms are defined at $q = 1$). Moreover, specializing $q = 1$ in β_n recovers the nth Bernoulli number B_n . These facts are far from trivial. To prove them, Carlitz was led to introduce q -analogues of the Stirling numbers of the second kind, $S_q(n, k)(n, k \in \mathbb{N}_0, n \geq k)$, which he defined via the following identity of q-polynomials:

$$
[X]^n = \sum_{k=0}^n q^{\frac{1}{2}k(k-1)} S_q(n,k) [X]_k
$$
\n(1.7)

(for all $n \in \mathbb{N}_0$). Specializing $q = 1$ in $S_q(n, k)$ $(n, k \in \mathbb{N}_0, n \geq k)$ recovers the classical Stirling numbers of the second kind $S(n, k)$. Using the $S_q(n, k)$'s, Carlitz [\[1\]](#page-23-0) established the following formula for β_n $(n \in \mathbb{N}_0)$:

$$
\beta_n = \sum_{k=0}^n (-1)^k \frac{[k]!}{[k+1]} S_q(n,k),\tag{1.8}
$$

which confirms that β_n is always well-defined at $q=1$, with value equal to the Bernoulli number B_n (according to (1.1)).

Carlitz also associated to the sequences $(\eta_n)_n$ and $(\beta_n)_n$ the q-polynomial sequences $(\eta_n(X))_n$ and $(\beta_n(X))_n$, given by:

$$
\eta_n(X) = \sum_{k=0}^n \binom{n}{k} \eta_k q^{kX} [X]^{n-k},\tag{1.9}
$$

$$
\beta_n(X) = \sum_{k=0}^n \binom{n}{k} \beta_k q^{kX} [X]^{n-k} \tag{1.10}
$$

(for all $n \in \mathbb{N}_0$). The original sequences $(\eta_n)_n$ and $(\beta_n)_n$ are then respectively obtained as the values of $(\eta_n(X))_n$ and $(\beta_n(X))_n$ at $X = 0$. Especially, $(\beta_n(X))_n$ constitutes a q-analogue of the classical Bernoulli polynomial sequence $(B_n(X))_n$. That said, alternative definitions of the Carlitz q-Bernoulli numbers and polynomials exist, such as those based on generating functions or p-adic q-integrals on \mathbb{Z}_p . For example, Koblitz [\[6\]](#page-24-5) constructed q-analogues of the p-adic Dirichlet L -series that interpolate the Carlitz q -Bernoulli numbers.

In this work, we first incorporate the Carlitz q-polynomial sequences $(\eta_n(X))_n$ and $(\beta_n(X))_n$ into a broader class of q -polynomial sequences, which we call "Carlitz-type q -polynomial sequences". We establish a fundamental theorem showing that this class of q -polynomial sequences serves as a q-analogue of the classical Appell polynomial sequences. Next, We verify that the closed forms of the q-analogues of power sums of consecutive natural numbers can essentially be expressed in terms of Carlitz-type q-polynomial sequences. Furthermore, we show that a specific subclass of Carlitz-type q-polynomial sequences $(\text{including } (\eta_n(X))_n$ and $(\beta_n(X))_n$ can be generated using simple symbolic formulas, such as those established by Carlitz in [\[1\]](#page-23-0). We then establish several properties of Carlitz-type q-polynomial sequences and leverage these properties to extend $(\eta_n(X))_n$ and $(\beta_n(X))_n$ into $(\beta_n^{(r)}(X))_n$ $(r \in \mathbb{N}_0)$, which provide important q-analogues of the classical Bernoulli polynomials for $r \geq 1$. Additionally, we represent

the numbers $\beta_n^{(r)} := \beta_n^{(r)}(0)$ as series and express them in terms of the q-Stirling numbers of the second kind. Finally, we derive a novel formula connecting the Carlitz q -Bernoulli numbers with the *q*-Stirling numbers of the second kind.

2 The results and the proofs

2.1 Carlitz-type q -polynomial sequences

We first introduce the following definition:

Definition 2.1. Let $(T_n(X))_{n \in \mathbb{N}_0}$ be a q-polynomial sequence. We say that $(T_n(X))_n$ is *Carlitztype* if its general term $T_n(X)$ ($n \in \mathbb{N}_0$) has the form:

$$
T_n(X) = (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} a_k q^{kX},
$$

where $(a_k)_{k \in \mathbb{N}_0}$ is a real sequence. In this case, $(a_k)_k$ is called *the associated sequence* of the Carlitz-type q-polynomial sequence $(T_n(X))_n$.

An important characterization of the Carlitz-type q-polynomial sequences is given by the following fundamental theorem:

Theorem 2.2. Let $(T_n(X))_{n \in \mathbb{N}_0}$ be a q-polynomial sequence, and for all $n \in \mathbb{N}_0$, set $t_n := T_n(0)$. *Then* $(T_n(X))_n$ *is Carlitz-type if and only if we have for all* $n \in \mathbb{N}_0$:

$$
T_n(X) = \sum_{k=0}^n \binom{n}{k} t_k q^{kX} [X]^{n-k},
$$

that is (symbolically):

$$
T_n(X) = (q^X t + [X])^n.
$$

To prove this theorem, we need to use the inversion formula from the following lemma:

Lemma 2.3 (see e.g, [\[2,](#page-24-6) [8\]](#page-24-7)). Let $(u_n)_{n \in \mathbb{N}_0}$ and $(v_n)_{n \in \mathbb{N}_0}$ be two real sequences. Then the two *following identities are equivalent:*

$$
u_n = \sum_{k=0}^n \binom{n}{k} v_k \qquad (\forall n \in \mathbb{N}_0),
$$

$$
v_n = \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} u_k \qquad (\forall n \in \mathbb{N}_0).
$$

Proof of Theorem [2.2.](#page-4-0) Suppose that $(T_n(X))_n$ is Carlitz-type. So there exists a real sequence $(a_n)_{n \in \mathbb{N}_0}$ for which we have for all $n \in \mathbb{N}_0$:

$$
T_n(X) = (q-1)^{-n} \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} a_k q^{kX}.
$$

In particular, we have for all $n \in \mathbb{N}_0$:

$$
t_n := T_n(0) = (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} a_k,
$$

that is

$$
(q-1)^n t_n = \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} a_k.
$$

By inverting this last formula (using Lemma [2.3\)](#page-4-1), we derive that for all $n \in \mathbb{N}_0$:

$$
a_n = \sum_{k=0}^n \binom{n}{k} (q-1)^k t_k.
$$

Then, by inserting this into the expression of $T_n(X)$, we obtain that for all $n \in \mathbb{N}_0$:

$$
T_n(X) = (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} \left(\sum_{i=0}^k \binom{k}{i} (q-1)^i t_i \right) q^{kX}
$$

$$
= (q-1)^{-n} \sum_{k=0}^n \sum_{i=0}^k (-1)^{n-k} \binom{n}{k} \binom{k}{i} (q-1)^i t_i q^{kX}.
$$

By inverting the summations and remarking that $\binom{n}{k}$ $\binom{n}{k}\binom{k}{i} = \binom{n}{i}$ $\binom{n}{i}\binom{n-i}{k-i}$ (for all $n \in \mathbb{N}_0$, $k \in$ ${0, 1, ..., n}$, and $i \in {0, 1, ..., k}$, we derive that for all $n \in \mathbb{N}_0$:

$$
T_n(X) = (q-1)^{-n} \sum_{0 \le i \le n} \sum_{i \le k \le n} (-1)^{n-k} \binom{n}{i} \binom{n-i}{k-i} (q-1)^i t_i q^{kX}
$$

= $(q-1)^{-n} \sum_{0 \le i \le n} \sum_{0 \le j \le n-i} (-1)^{n-i-j} \binom{n}{i} \binom{n-i}{j} (q-1)^i t_i q^{(i+j)X}$ (where we set $j = k - i$)
= $(q-1)^{-n} \sum_{0 \le i \le n} \binom{n}{i} (q-1)^i t_i q^{iX} \sum_{0 \le j \le n-i} \binom{n-i}{j} q^{jX} (-1)^{n-i-j}.$

But according to the binomial formula, we have for all $n \in \mathbb{N}_0$ and all $i \in \{0, 1, \ldots, n\}$:

$$
\sum_{0 \le j \le n-i} \binom{n-i}{j} q^{jX} (-1)^{n-i-j} = (q^X - 1)^{n-i} = (q-1)^{n-i} [X]^{n-i}.
$$

By inserting this into the last obtained expression for $T_n(X)$, we finally derive that for all $n \in \mathbb{N}_0$:

$$
T_n(X) = \sum_{0 \le i \le n} \binom{n}{i} t_i q^{iX} [X]^{n-i},
$$

as required.

Conversely, suppose that we have for all $n \in \mathbb{N}_0$:

$$
T_n(X) = \sum_{k=0}^n \binom{n}{k} t_k q^{kX} [X]^{n-k},
$$

and define for all $n \in \mathbb{N}_0$:

$$
a_n := \sum_{k=0}^n \binom{n}{k} (q-1)^k t_k \tag{2.1}
$$

and

$$
S_n(X) := (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} a_k q^{kX}.
$$

Equivalently, $(S_n(X))_{n\in\mathbb{N}_0}$ is a Carlitz-type q-polynomial sequence, with associated sequence $(a_n)_{n\in\mathbb{N}_0}$. So, according to the first part of this proof, we have for all $n \in \mathbb{N}_0$:

$$
S_n(X) = \sum_{k=0}^{n} {n \choose k} s_k q^{kX} [X]^{n-k},
$$
\n(2.2)

where

$$
s_n := S_n(0) = (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} a_k.
$$
 (2.3)

But the inversion of Formula [\(2.1\)](#page-5-0) (using Lemma [2.3\)](#page-4-1) gives for all $n \in \mathbb{N}_0$:

$$
(q-1)^n t_n = \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} a_k,
$$

that is

$$
t_n = (q-1)^{-n} \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} a_k = s_n
$$

(according to [\(2.3\)](#page-6-0)). Hence we have for all $n \in \mathbb{N}_0$:

$$
T_n(X) = \sum_{k=0}^n {n \choose k} t_k q^{kX} [X]^{n-k}
$$

=
$$
\sum_{k=0}^n {n \choose k} s_k q^{kX} [X]^{n-k}
$$

=
$$
S_n(X) \qquad \text{(according to (2.2))}.
$$

Consequently $(T_n(X))_n = (S_n(X))_n$ is Carlitz-type, as required. This complete this proof. \Box

Remark 2.4*.* From the perspective of Theorem [2.2,](#page-4-0) the Carlitz-type q-polynomial sequences can be regarded as a q-analogue of the Appell polynomial sequences.

Examples 2.5*.* In [\[1\]](#page-23-0), Carlitz introduced two important q-polynomial sequences, which are $(\eta_n(X))_{n \in \mathbb{N}_0}$ and $(\beta_n(X))_{n \in \mathbb{N}_0}$, defined for all $n \in \mathbb{N}_0$ by:

$$
\eta_n(X) := (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} \frac{k}{[k]} q^{kX},\tag{2.4}
$$

$$
\beta_n(X) := (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} \frac{k+1}{[k+1]} q^{kX} \tag{2.5}
$$

(where we take by convention $\frac{k}{[k]} = 1$ for $k = 0$). From their definitions, it is clear that $(\eta_n(X))_n$ and $(\beta_n(X))_n$ are both Carlitz-type with associated real sequences $(\frac{k}{[k]})_k$ and $(\frac{k+1}{[k+1]})_k$

respectively. In addition, Carlitz [\[1\]](#page-23-0) explored the real sequences constituted of the values of $(\eta_n(X))_n$ and $(\beta_n(X))_n$ at $X = 0$; that is the sequences $(\eta_n)_{n \in \mathbb{N}_0}$ and $(\beta_n)_{n \in \mathbb{N}_0}$, defined by:

$$
\eta_n := \eta_n(0) \text{ and } \beta_n := \beta_n(0) \quad (\forall n \in \mathbb{N}_0).
$$

So, according to Theorem [2.2,](#page-4-0) we have important alternative expressions for $\eta_n(X)$ and $\beta_n(X)$ $(n \in \mathbb{N}_0)$, which are

$$
\eta_n(X) = \sum_{k=0}^n \binom{n}{k} \eta_k q^{kX} [X]^{n-k},\tag{2.6}
$$

$$
\beta_n(X) = \sum_{k=0}^n \binom{n}{k} \beta_k q^{kX} [X]^{n-k}.
$$
\n(2.7)

Using the symbolic calculus, Formulas (2.6) and (2.7) can be written more simply as:

$$
\eta_n(X) = \left(q^X \eta + [X] \right)^n, \tag{2.8}
$$

$$
\beta_n(X) = (q^X \beta + [X])^n \tag{2.9}
$$

(for all $n \in \mathbb{N}_0$).

We now see that Carlitz-type q-polynomial sequences naturally emerge when deriving closed-form expressions for q-analogues of power sums of consecutive positive integers. We begin with the following theorem:

Theorem 2.6. *Let* r *be a positive integer. For all nonnegative integer* n *and all positive integer* N*, we have*

$$
\sum_{k=0}^{N-1} q^{rk} [k]^n = q^{rN} S_n(N) - S_n(0),
$$

 $where (S_k(X))_{k \in \mathbb{N}_0}$ is the Carlitz-type q-polynomial sequence associated to the real sequence of *general term* $a_k = \frac{1}{a_k}$ $q-1$ 1 $\frac{1}{[k+r]}$ $(\forall k \in \mathbb{N}_0).$

Proof. Let $n \in \mathbb{N}_0$ and $N \in \mathbb{N}$ be fixed. We have

$$
\sum_{k=0}^{N-1} q^{rk} [k]^n = \sum_{k=0}^{N-1} q^{rk} \left(\frac{q^k - 1}{q - 1}\right)^n
$$

= $(q - 1)^{-n} \sum_{k=0}^{N-1} q^{rk} (q^k - 1)^n$
= $(q - 1)^{-n} \sum_{k=0}^{N-1} q^{rk} \sum_{i=0}^n {n \choose i} q^{ki} (-1)^{n-i}$ (by the binomial formula)
= $(q - 1)^{-n} \sum_{i=0}^n (-1)^{n-i} {n \choose i} \sum_{k=0}^{N-1} q^{(i+r)k}$
= $(q - 1)^{-n} \sum_{i=0}^n (-1)^{n-i} {n \choose i} \frac{q^{(i+r)N} - 1}{q^{i+r} - 1}$
= $(q - 1)^{-n} \sum_{i=0}^n (-1)^{n-i} {n \choose i} \frac{1}{(q - 1)[i + r]} (q^{(i+r)N} - 1).$

Setting for all $n \in \mathbb{N}_0$:

$$
S_n(X) := (q-1)^{-n} \sum_{i=0}^n (-1)^{n-i} \binom{n}{i} \frac{1}{(q-1)[i+r]} q^{iX}
$$

 $(\mathrm{so}(S_n(X))_n)$ is the Carlitz-type q-polynomial sequence associated to the real sequence of general term $a_i = \frac{1}{(a-1)}$ $\frac{1}{(q-1)[i+r]}$, we conclude that:

$$
\sum_{n=0}^{N-1} q^{rk} [k]^n = q^{rN} S_n(N) - S_n(0),
$$

as required.

The following generalization of Theorem [2.6](#page-7-0) aims to provide a larger class of real sequences, for which the associated Carlitz-type q -polynomial sequences naturally arise when evaluating q-analogues of power sums of consecutive positive integers.

Theorem 2.7. Let r be a positive integer and d be a nonnegative integer such that $r \geq d$. For *all integer* n ≥ d *and all positive integer* N*, we have*

$$
\sum_{k=0}^{N-1} q^{rk} [k]^{n-d} = \frac{q^{(r-d)N} T_n(N) - T_n(0)}{n(n-1)\cdots(n-d+1)},
$$

 $where \left(T_k(X)\right)_{k \in \mathbb{N}_0}$ *is the Carlitz-type* q-polynomial sequence associated to the real sequence of *general term*

$$
b_k = (q-1)^{d-1} \frac{k(k-1)\cdots(k-d+1)}{[k+r-d]} \qquad (\forall k \in \mathbb{N}_0).
$$

Proof. Let n and N be fixed integers such that $n \geq d$ and $N \geq 1$. According to Theorem [2.6,](#page-7-0) we have that

$$
\sum_{k=0}^{N-1} q^{rk} [k]^{n-d} = q^{rN} S_{n-d}(N) - S_{n-d}(0),
$$

where $(S_k(X))_{k \in \mathbb{N}_0}$ is the Carlitz-type q-polynomial sequence associated to the real sequence of general term $a_k = \frac{1}{(a-1)!}$ $\frac{1}{(q-1)[k+r]}$ (∀ $k \in \mathbb{N}_0$). By introducing the q-polynomial sequence $(T_k(X))_{k \in \mathbb{N}_0}$ defined by:

$$
T_k(X) = \begin{cases} 0 & \text{if } k < d \\ k(k-1)\cdots(k-d+1)q^{dX}S_{k-d}(X) & \text{else} \end{cases} \qquad (\forall k \in \mathbb{N}_0),
$$

the closed form of the sum of q -powers above is transformed to

$$
\sum_{k=0}^{N-1} q^{rk} [k]^{n-d} = \frac{q^{(r-d)N} T_n(N) - T_n(0)}{n(n-1)\cdots(n-d+1)}.
$$

So it remains to verify that $(T_k(X))_k$ is Carlitz-type with the associated sequence that given by the theorem. For an integer $k \geq d$, we have

$$
T_k(X) := k(k-1)\cdots(k-d+1)q^{dX}S_{k-d}(X)
$$

9

$$
= k(k - 1) \cdots (k - d + 1)q^{dX} \cdot (q - 1)^{-k+d} \sum_{i=0}^{k-d} (-1)^{k-d-i} {k - d \choose i} \frac{1}{(q - 1)[i + r]} q^{iX}
$$

= $k(k - 1) \cdots (k - d + 1)q^{dX} (q - 1)^{-k+d} \sum_{j=d}^{k} (-1)^{k-j} {k - d \choose j - d} \frac{1}{(q - 1)[j + r - d]} q^{(j - d)X}$

(by setting $j = i + d$). But since $k(k-1)\cdots(k-d+1)\binom{k-d}{i-d}$ j_{j-d}^{k-d}) = $j(j-1)\cdots(j-d+1){k \choose j}$ $\binom{k}{j}$ (for all integers $k, j \ge d$, it follows that for all integer $k \ge d$:

$$
T_k(X) = (q-1)^{-k} \sum_{j=d}^k (-1)^{k-j} {k \choose j} (q-1)^{d-1} \frac{j(j-1)\cdots(j-d+1)}{[j+r-d]} q^{jX}
$$

= $(q-1)^{-k} \sum_{j=0}^k (-1)^{k-j} {k \choose j} (q-1)^{d-1} \frac{j(j-1)\cdots(j-d+1)}{[j+r-d]} q^{jX}.$

By remarking that the last formula for $T_k(X)$ is obviously valid for $0 \leq k \leq d$, we conclude that $(T_k(X))_k$ is Carlitz-type and its associated real sequence has the general term $b_j = (q-1)^{d-1} \frac{j(j-1)\cdots(j-d+1)}{[j+r-d]}$ $(\forall j \in \mathbb{N}_0)$. The theorem is thus proved. \Box

Remark 2.8. It is important to note that the general term of the real sequence $(b_k)_{k \in \mathbb{N}_0}$ as-sociated to the q-polynomial sequence in Theorem [2.7](#page-8-0) has the form $\frac{P(k)}{[k+s]}$, with P is a real polynomial and s is a nonnegative integer. This fact will be used below for establishing some important symbolic formulas.

In the following theorem, we will establish symbolic formulas generating the values at 0 of some particular Carlitz-type q-polynomial sequences.

Theorem 2.9. *Let* r *and* d *be two nonnegative integers and* P *be a real polynomial of degree* d*.* Let also $(T_n(X))_{n\in\mathbb{N}_0}$ be the Carlitz-type q-polynomial sequence whose associated real sequence $is\left(\frac{P(k)}{[k+r]}\right)$ $\frac{P(k)}{[k+r]}$ $\lim_{k \in \mathbb{N}_0}$ and $(t_n)_{n \in \mathbb{N}_0}$ be the real sequence defined by $t_n := T_n(0)$ ($\forall n \in \mathbb{N}_0$). Then $(t_n)_n$ *satisfies the symbolic formula:*

$$
q^r (qt+1)^n = t^n \qquad (\forall n > d).
$$

Proof. Let $n > d$ be a fixed integer. From the definition of $T_n(X)$, we have that

$$
T_n(X) = (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} \frac{P(k)}{[k+r]} q^{kX}.
$$

Thus

$$
q^{r}T_{n}(1) - T_{n}(0) = (q - 1)^{-n} \sum_{k=0}^{n} (-1)^{n-k} {n \choose k} \frac{P(k)}{[k+r]} (q^{k+r} - 1)
$$

= $(q - 1)^{-n+1} \sum_{k=0}^{n} (-1)^{n-k} {n \choose k} P(k)$ (since $q^{k+r} - 1 = (q - 1)[k+r]$)
= $(q - 1)^{-n+1} (\Delta^{n} P) (0)$ (according to (1.3))
= 0 (since $n > \text{deg} P = d$).

Consequently, we have

$$
q^r T_n(1) = T_n(0) = t_n. \tag{2.10}
$$

On the other hand, we have (according to Theorem [2.2\)](#page-4-0) the symbolic formula:

$$
T_n(X) = (q^X t + [X])^n.
$$

In particular, we have symbolically

$$
T_n(1) = (qt+1)^n.
$$

By inserting this into [\(2.10\)](#page-10-0), it finally follows that we have symbolically

$$
q^r (qt+1)^n = t^n,
$$

as required.

Examples 2.10*.*

1. Since the general term of the associated real sequences of the Carlitz-type q-polynomial sequences $(\eta_n(X))_{n \in \mathbb{N}_0}$ and $(\beta_n(X))_{n \in \mathbb{N}_0}$ are respectively $\frac{k}{[k]}$ and $\frac{k+1}{[k+1]}$ then (according to Theorem [2.9\)](#page-9-0) the real sequences $(\eta_n)_{n \in \mathbb{N}_0}$ and $(\beta_n)_{n \in \mathbb{N}_0}$ satisfy the symbolic formulas:

$$
(q\eta + 1)^n = \eta^n
$$

$$
q (q\beta + 1)^n = \beta^n
$$
 (\forall n > 1).

2. Let us put ourselves in the situation of Theorem [2.7](#page-8-0) and set $t_k := T_k(0)$ (for all $k \in \mathbb{N}_0$). Since the general term of the associated real sequence of the Carlitz-type q-polynomial sequence $(T_k(X))_k$ has the form $\frac{P(k)}{[k+r-d]}$, where P is a real polynomial of degree d, then (according to Theorem [2.9\)](#page-9-0) the sequence $(t_k)_k$ satisfy the symbolic formula:

$$
q^{r-d} (qt+1)^k = t^k \qquad (\forall k > d).
$$

In the following proposition, we provide some important properties of Carlitz-type qpolynomial sequences. For simplicity, given a real or functional sequence $(f_n)_{n\in\mathbb{N}_0}$, we denote (with a slight abuse of notation) by $(nf_{n-1})_{n\in\mathbb{N}_0}$ the sequence whose terms are defined as

$$
\begin{cases} 0 & \text{if } n = 0, \\ nf_{n-1} & \text{otherwise} \end{cases}.
$$

Proposition 2.11. Let $(T_n(X))_{n \in \mathbb{N}_0}$ be a Carlitz-type q-polynomial sequence and $(a_k)_{k \in \mathbb{N}_0}$ be *its associated real sequence. Then the following properties hold.*

1. The q-polynomial sequence $(q^X n T_{n-1}(X))_{n \in \mathbb{N}_0}$ is Carlitz-type with associated real sequence $((q-1)ka_{k-1})_{k \in \mathbb{N}_0}$.

- 2. If $T_0(X) = 0$ _{*c*} (i.e., $a_0 = 0$) then the q-polynomial sequence $\left(\frac{q^{-X}T_{n+1}(X)}{n+1}\right)_{n \in \mathbb{N}_0}$ is Carlitz*type with associated real sequence* $\left(\frac{1}{q}\right)$ $q-1$ $\frac{a_{k+1}}{k+1}\Big)_{k\in\mathbb{N}_0}.$
- 3. The sequence $(q^{-X}(T_n(X) + (q-1)T_{n+1}(X)))_{n \in \mathbb{N}_0}$ is a Carlitz-type q-polynomial sequence $with\ associated\ real\ sequence\ $(a_{k+1})_{k\in\mathbb{N}_0}$$ *.*
- 4. The q-polynomial sequence $(n (T_{n-1}(X) + (q-1)T_n(X)))_{n \in \mathbb{N}_0}$ is Carlitz-type with asso*ciated real sequence* $((q-1)ka_k)_{k \in \mathbb{N}_0}$.

Proof. By definition, we have for all $n \in \mathbb{N}_0$:

$$
T_n(X) = (q-1)^{-n} \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} a_k q^{kX}.
$$
 (2.11)

• Let us show the 1st item of the proposition. Using [\(2.11\)](#page-11-0), we have for all $n \in \mathbb{N}_0$:

$$
q^{X}nT_{n-1}(X) = (q-1)^{-n+1} \sum_{k=0}^{n-1} (-1)^{n-1-k} n {n-1 \choose k} a_k q^{(k+1)X}
$$

= $(q-1)^{-n} \sum_{k=1}^{n} (-1)^{n-k} n {n-1 \choose k-1} (q-1) a_{k-1} q^{kX}.$

Remarking that $n\binom{n-1}{k-1}$ $\binom{n-1}{k-1} = k \binom{n}{k}$ ${k \choose k}$ (for all $1 \leq k \leq n$), it follows that for all $n \in \mathbb{N}_0$:

$$
q^X n T_{n-1}(X) = (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} ((q-1)ka_{k-1}) q^{kX},
$$

showing that the q-polynomial sequence $(q^X n T_{n-1}(X))_{n \in \mathbb{N}_0}$ is Carlitz-type with associated real sequence $((q-1)ka_{k-1})_{k\in\mathbb{N}_0}$. The first item of the proposition is proved.

• Next, let us show the 2nd item of the proposition. So, suppose that $T_0(X) = 0_{\mathscr{E}}$, that is $a_0 = 0$. Using [\(2.11\)](#page-11-0), we have for all $n \in \mathbb{N}_0$:

$$
q^{-X} \frac{T_{n+1}(X)}{n+1} = (q-1)^{-n-1} \sum_{k=1}^{n+1} (-1)^{n+1-k} \frac{1}{n+1} {n+1 \choose k} a_k q^{(k-1)X}
$$

= $(q-1)^{-n} \sum_{k=0}^{n} (-1)^{n-k} \frac{1}{n+1} {n+1 \choose k+1} \frac{1}{q-1} a_{k+1} q^{kX}.$

Remarking that $\frac{1}{n+1} {n+1 \choose k+1} = \frac{1}{k+1} {n \choose k}$ ${k \choose k}$ (for all $0 \le k \le n$), it follows that for all $n \in \mathbb{N}_0$:

$$
q^{-X} \frac{T_{n+1}(X)}{n+1} = (q-1)^{-n} \sum_{k=0}^{n} (-1)^{n-k} {n \choose k} \left(\frac{1}{q-1} \frac{a_{k+1}}{k+1} \right) q^{kX},
$$

showing that the q-polynomial sequence $(q^{-X}\frac{T_{n+1}(X)}{n+1})_{n\in\mathbb{N}_0}$ is Carlitz-type with associated real sequence $\left(\frac{1}{a}\right)$ $q-1$ $\binom{a_{k+1}}{k+1}_{k \in \mathbb{N}_0}$. The second item of the proposition is proved.

• Now, let us show the 3rd item of the proposition. Using [\(2.11\)](#page-11-0), we have for all $n \in \mathbb{N}_0$:

$$
q^{-X}(T_n(X) + (q-1)T_{n+1}(X)) = (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} {n \choose k} a_k q^{(k-1)X}
$$

+
$$
(q-1)^{-n} \sum_{k=0}^{n+1} (-1)^{n+1-k} {n+1 \choose k} a_k q^{(k-1)X}
$$

=
$$
(q-1)^{-n} \sum_{k=0}^{n+1} (-1)^{n-k+1} \left({n+1 \choose k} - {n \choose k} \right) a_k q^{(k-1)X}.
$$

But since $\binom{n+1}{k}$ $\binom{+1}{k} - \binom{n}{k}$ $\binom{n}{k} =$ $\sqrt{ }$ \int \mathcal{L} 0 if $k = 0$ $\binom{n}{k}$ $\binom{n}{k-1}$ if $k \geq 1$ (for all $0 \leq k \leq n+1$), it follows that:

$$
q^{-X}(T_n(X) + (q-1)T_{n+1}(X)) = (q-1)^{-n} \sum_{k=1}^{n+1} (-1)^{n-k+1} {n \choose k-1} a_k q^{(k-1)X}
$$

$$
= (q-1)^{-n} \sum_{k=0}^{n} (-1)^{n-k} {n \choose k} a_{k+1} q^{kX},
$$

showing that the sequence $(q^{-X}(T_n(X) + (q-1)T_{n+1}(X)))_{n \in \mathbb{N}_0}$ is q-polynomial of Carlitz-type with associated real sequence $(a_{k+1})_{k \in \mathbb{N}_0}$. The third item of the proposition is proved.

• Finally, the $4th$ item of the proposition follows by successively applying its $3rd$ and $1st$ items, which have already been proven. This completes the proof. \Box

Example 2.12. Since the real sequence associated to $(\eta_n(X))_{n\in\mathbb{N}_0}$ (which is a Carlitz-type qpolynomial sequence) is $\left(\frac{k}{[k]}\right)_{k \in \mathbb{N}_0}$ then (according to Item 3 of Proposition [2.11\)](#page-10-1) the sequence $(q^{-X}(\eta_n(X) + (q-1)\eta_{n+1}(X)))_{n \in \mathbb{N}_0}$ is a Carlitz-type q-polynomial sequence with associated real sequence $\left(\frac{k+1}{[k+1]}\right)_{k\in\mathbb{N}_0}$. Hence $(q^{-X}(\eta_n(X)+(q-1)\eta_{n+1}(X)))$ coincides with $(\beta_n(X))_n$; that is

$$
\beta_n(X) = q^{-X} \left(\eta_n(X) + (q-1)\eta_{n+1}(X) \right) \qquad (\forall n \in \mathbb{N}_0). \tag{2.12}
$$

.

We now derive from Theorem [2.7](#page-8-0) formulas for q -analogues of sums of powers of positive integers, which involve the q-polynomial sequences $(\eta_n(X))_{n \in \mathbb{N}_0}$ and $(\beta_n(X))_{n \in \mathbb{N}_0}$ introduced by Carlitz in [\[1\]](#page-23-0). The following corollaries are obtained:

Corollary 2.13. *For all positive integers* n *and* N*, we have*

$$
\sum_{k=0}^{N-1} q^k [k]^{n-1} = \frac{\eta_n(N) - \eta_n}{n}
$$

Proof. Take in Theorem [2.7:](#page-8-0) $r = d = 1$.

Corollary 2.14. *For all positive integers* n *and* N*, we have*

$$
n\sum_{k=0}^{N-1} q^{2k} [k]^{n-1} + (q-1) \sum_{k=0}^{N-1} q^k [k]^n = q^N \beta_n(N) - \beta_n.
$$

Proof. Let n and N be fixed positive integers. By applying Theorem [2.7](#page-8-0) for the couples $(r, d) = (2, 1)$ and $(r, d) = (1, 0)$, we respectively obtain the two following formulas:

$$
\sum_{k=0}^{N-1} q^{2k} [k]^{n-1} = \frac{q^N T_n(N) - T_n(0)}{n},
$$

$$
\sum_{k=0}^{N-1} q^k [k]^n = q^N S_n(N) - S_n(0),
$$

where $(T_k(X))_{k \in \mathbb{N}_0}$ and $(S_k(X))_{k \in \mathbb{N}_0}$ represent the Carlitz-type q-polynomial sequences, associated respectively to the real sequences $\left(\frac{k}{[k+1]}\right)_{k \in \mathbb{N}_0}$ and $\left(\frac{1}{q-1}\right)_{k \in \mathbb{N}_0}$ $q-1$ $\frac{1}{[k+1]}$ _{$k \in \mathbb{N}_0$}. By combining the two above formulas, we derive that:

$$
n\sum_{k=0}^{N-1} q^{2k} [k]^{n-1} + (q-1) \sum_{k=0}^{N-1} q^k [k]^n = q^N U_n(N) - U_n(0),
$$

where

$$
U_k(X) := T_k(X) + (q-1)S_k(X) \qquad (\forall k \in \mathbb{N}_0).
$$

Next, from the fact that $(T_k(X))_k$ and $(S_k(X))_k$ are Carlitz-type q-polynomial sequences whose associated real sequences are respectively $\left(\frac{k}{[k+1]}\right)_k$ and $\left(\frac{1}{q-1}\right)_k$ $q-1$ $\frac{1}{[k+1]}$, we derive that $(U_k(X))_k$ is also a Carlitz-type q-polynomial sequence, with an associated real sequence having the general term:

$$
\frac{k}{[k+1]} + (q-1)\left(\frac{1}{q-1}\frac{1}{[k+1]}\right) = \frac{k+1}{[k+1]}
$$
 (\forall k \in \mathbb{N}_0).

Consequently, $(U_k(X))_k$ is nothing else than the q-polynomial sequence $(\beta_k(X))_k$ of Carlitz q-Bernoulli polynomials. This completes the proof. \Box

2.2 Extended Carlitz q-Bernoulli numbers and polynomials

2.2.1 Definitions and basic results

We begin by introducing the following definition:

Definition 2.15. We define $(\beta_n^{(r)}(X))$ r,n∈ \mathbb{N}_0 recursively by:

$$
\beta_n^{(0)}(X) := \eta_n(X) \tag{2.13}
$$

$$
\beta_n^{(r+1)}(X) := q^{-X} \left(\beta_n^{(r)}(X) + (q-1)\beta_{n+1}^{(r)}(X) \right) \qquad (\forall r, n \in \mathbb{N}_0). \tag{2.14}
$$

Besides, we define $(\beta_n^{(r)})$ $\sum_{r,n\in\mathbb{N}_0}$ by:

$$
\beta_n^{(r)} := \beta_n^{(r)}(0) \qquad (\forall r, n \in \mathbb{N}_0). \tag{2.15}
$$

So, it follows from (2.13) and (2.14) that:

$$
\beta_n^{(0)} = \eta_n \qquad (\forall n \in \mathbb{N}_0), \qquad (2.16)
$$

$$
\beta_n^{(r+1)} = \beta_n^{(r)} + (q-1)\beta_{n+1}^{(r)} \qquad (\forall r, n \in \mathbb{N}_0). \tag{2.17}
$$

Since $(\beta_n^{(0)}(X))$ $\eta_{n\in\mathbb{N}_0} = (\eta_n(X))_{n\in\mathbb{N}_0}$ is a Carlitz-type q-polynomial sequence (see Examples [2.5\)](#page-6-2) then (according to Item 3 of Proposition [2.11](#page-10-1) and a simple induction on r) all the sequences $\left(\beta_n^{(r)}(X)\right)$ $_{n\in\mathbb{N}_0}$ ($r \in \mathbb{N}_0$) are Carlitz-type q-polynomial sequences.

Definition 2.16. Giving $r \in \mathbb{N}_0$, the q-polynomials $\beta_n^{(r)}(X)$ $(n \in \mathbb{N}_0)$ are called *the extended Carlitz* q-Bernoulli polynomials of order r, and the numbers $\beta_n^{(r)}$ $(n \in \mathbb{N}_0)$ are called the extended *Carlitz* q*-Bernoulli numbers of order* r.

Taking $r = 0$ in [\(2.14\)](#page-13-1), we find in particular that for all $n \in \mathbb{N}_0$:

$$
\beta_n^{(1)}(X) = q^{-X} \left(\eta_n(X) + (q-1)\eta_{n+1}(X) \right) = \beta_n(X)
$$

(according to (2.12)). So, the Carlitz q-Bernoulli polynomials of order 1 are nothing else than the Carlitz q-Bernoulli polynomials $\beta_n(X)$ (introduced by Carlitz in [\[1\]](#page-23-0)). Consequently, the Carlitz q -Bernoulli numbers of order 1 are nothing else than the Carlitz q -Bernoulli numbers β_n of [\[1\]](#page-23-0). Furthermore, Carlitz [1] showed that the q-polynomials $\beta_n(X) = \beta_n^{(1)}(X)$ $(n \in \mathbb{N}_0)$ are well-defined for $q = 1$ and coincide with the Bernoulli polynomials when specializing q to 1; that is $\beta_n^{(1)}(X)|_{q=1} = B_n(X)$ for all $n \in \mathbb{N}_0$. Consequently, in view of [\(2.14\)](#page-13-1), the q-polynomials $\beta_n^{(r)}(X)$ $(r \in \mathbb{N}, n \in \mathbb{N}_0)$ are also well-defined for $q = 1$, and for all $r \in \mathbb{N}$ and $n \in \mathbb{N}_0$, we have:

$$
\beta_n^{(r+1)}(X)|_{q=1} = \beta_n^{(r)}(X)|_{q=1}.
$$

By induction on r, it follows that for all $r \in \mathbb{N}$ and $n \in \mathbb{N}_0$:

$$
\beta_n^{(r)}(X)|_{q=1} = \beta_n^{(1)}(X)|_{q=1} = B_n(X).
$$

This demonstrates that for all $r \in \mathbb{N}$, the q-polynomials $\beta_n^{(r)}(X)$ $(n \in \mathbb{N}_0)$ can serve as a q-analogue of the classical Bernoulli polynomials. In view of [\(2.15\)](#page-13-2), it follows that for all $r \in \mathbb{N}$, the numbers $\beta_n^{(r)}$ $(n \in \mathbb{N}_0)$ can also serve as a q-analogue of the classical Bernoulli numbers. This justify the terminology introduced in Definition [2.16.](#page-13-3)

The following proposition gathers several formulas for the Carlitz q -Bernoulli polynomials and numbers of a given order, which can be directly derived from the results of §[2.1.](#page-4-2)

Proposition 2.17. *For all* $r, n \in \mathbb{N}_0$ *, we have that:*

$$
\beta_n^{(r)}(X) = (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} \frac{k+r}{[k+r]} q^{kX},\tag{2.18}
$$

$$
\beta_n^{(r)} = (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} \frac{k+r}{[k+r]},\tag{2.19}
$$

$$
\beta_n^{(r)}(X) = \sum_{k=0}^n \binom{n}{k} \beta_k^{(r)} q^{kX} [X]^{n-k}.
$$
\n(2.20)

In addition, for a given $r \in \mathbb{N}_0$ *, the Carlitz* q-Bernoulli polynomials and numbers of order r *satisfy the following symbolic formulas:*

$$
q^{r} (q\beta^{(r)} + 1)^{n} = (\beta^{(r)})^{n} \qquad (\forall n \ge 2), \qquad (2.21)
$$

$$
\beta_n^{(r)}(X) = \left(q^X \beta^{(r)} + [X]\right)^n \qquad (\forall n \in \mathbb{N}_0). \tag{2.22}
$$

 \Box

Proof. Using Item 3 of Proposition [2.11](#page-10-1) together with Formula (2.14) , we immediately show by induction that for all $r \in \mathbb{N}_0$, the associated real sequence of the Carlitz-type q-polynomial sequence $(\beta_n^{(r)}(X))$ $_{n\in\mathbb{N}_0}$ is $\left(\frac{k+r}{[k+r]}\right)$ $\frac{k+r}{[k+r]}$ Formula (2.18) of the proposition then follows. Next, Formula [\(2.19\)](#page-14-1) of the proposition follows by taking $X = 0$ in Formula [\(2.18\)](#page-14-0), which we have just proven. Formulas [\(2.20\)](#page-14-2) and [\(2.22\)](#page-14-3) of the proposition immediately follow from Theorem [2.2.](#page-4-0) Finally, Formula [\(2.21\)](#page-14-4) of the proposition immediately follows from Theorem [2.9.](#page-9-0) This completes this proof. \Box

We now see, for a general $r \in \mathbb{N}_0$, how the q-polynomials $\beta_n^{(r)}(X)$ arise in q-analogues of sums of powers of consecutive positive integers. We have the following theorem providing a generalization of Corollaries [2.13](#page-12-1) and [2.14.](#page-12-2)

Theorem 2.18. *Let* r *be a nonnegative integer. Then we have for all positive integers* n *and* N*:*

$$
n\sum_{k=0}^{N-1} q^{(r+1)k} [k]^{n-1} + (q-1)r \sum_{k=0}^{N-1} q^{rk} [k]^{n} = q^{rN} \beta_{n}^{(r)}(N) - \beta_{n}^{(r)}.
$$

Proof. Let n and N be fixed positive integers. By applying Theorem [2.7](#page-8-0) for the couples $(r, 0)$ and $(r + 1, 1)$ (instead of (r, d)), we respectively obtain the two following formulas:

$$
\sum_{k=0}^{N-1} q^{rk}[k]^n = q^{rN}T_n(N) - T_n(0),
$$

$$
\sum_{k=0}^{N-1} q^{(r+1)k}[k]^{n-1} = \frac{q^{rN}S_n(N) - S_n(0)}{n},
$$

where $(T_k(X))_{k\in\mathbb{N}_0}$ and $(S_k(X))_{k\in\mathbb{N}_0}$ are the Carlitz-type q-polynomial sequences associated respectively to the real sequences of general term:

$$
a_k = \frac{1}{q-1} \frac{1}{[k+r]} \quad \text{and} \quad b_k = \frac{k}{[k+r]} \qquad (\forall k \in \mathbb{N}_0).
$$

By combining the above formulas, we derive that:

$$
n\sum_{k=0}^{N-1} q^{(r+1)k} [k]^{n-1} + (q-1)r \sum_{k=0}^{N-1} q^{rk} [k]^{n} = q^{rN} U_{n}(N) - U_{n}(0),
$$

where

$$
U_k(X) := S_k(X) + (q-1)rT_k(X) \qquad (\forall k \in \mathbb{N}_0).
$$

On the other hand, from the fact that $(T_k(X))_k$ and $(S_k(X))_k$ are Carlitz-type q-polynomial sequences whose associated real sequences are respectively $\left(\frac{1}{a}\right)$ $q-1$ 1 $\frac{1}{[k+r]}$ $_{k}$ and $\left(\frac{k}{\left[k+\right]}\right)$ $\frac{k}{[k+r]}$ κ , we derive that $(U_k(X))_k$ is also a Carlitz-type q-polynomial sequence, with an associated real sequence having the general term:

$$
\frac{k}{[k+r]} + (q-1)r\left(\frac{1}{q-1}\frac{1}{[k+r]}\right) = \frac{k+r}{[k+r]} \qquad (\forall k \in \mathbb{N}_0).
$$

Hence $(U_k(X))_k$ coincides with $(\beta_k^{(r)})$ $_{k}^{(r)}(X)\Big)$ κ , concluding to the required result.

.

.

,

2.2.2 Representation of the $\beta_n^{(r)}$'s as series

We now turn our attention to the representation of the extended Carlitz q -Bernoulli numbers $\beta_n^{(r)}$ as numerical series. We have the following theorem:

Theorem 2.19. *Suppose that* $|q| < 1$ *. Then we have for all* $r \in \mathbb{N}_0$ *and* $n \in \mathbb{N}$ *:*

$$
\beta_n^{(r)} = \begin{cases}\n-n \sum_{k=0}^{+\infty} q^k [k]^{n-1} + (1-q)^{-n} & \text{if } r = 0 \\
-n \sum_{k=0}^{+\infty} q^{(r+1)k} [k]^{n-1} + r(1-q) \sum_{k=0}^{+\infty} q^{rk} [k]^n & \text{else}\n\end{cases}
$$

Proof. The result follows by letting $N \to +\infty$ in the formula of Theorem [2.18.](#page-15-0) However, before doing so, we must evaluate $\lim_{N\to+\infty} q^{rN} \beta_n^{(r)}(N)$ (for given $r \in \mathbb{N}_0$, $n \in \mathbb{N}$). To achieve this, we use Formula [\(2.18\)](#page-14-0) of Proposition [2.17.](#page-14-5) Let $r \in \mathbb{N}_0$ and $n, N \in \mathbb{N}$ be fixed. According to Formula [\(2.18\)](#page-14-0) of Proposition [2.17,](#page-14-5) we have that:

$$
\beta_n^{(r)}(N) = (q-1)^{-n} \sum_{k=0}^n (-1)^{n-k} {n \choose k} \frac{k+r}{[k+r]} q^{kN}
$$

= $(q-1)^{-n} \left[(-1)^n \frac{r}{[r]} + \sum_{k=1}^n (-1)^{n-k} {n \choose k} \frac{k+r}{[k+r]} q^{kN} \right].$

Since $|q|$ < 1 by hypothesis, we derive that:

$$
\lim_{N \to +\infty} \beta_n^{(r)}(N) = (1 - q)^{-n} \frac{r}{[r]}.
$$

Thus

$$
\lim_{N \to +\infty} q^{rN} \beta_n^{(r)}(N) = \begin{cases} \lim_{N \to +\infty} \beta_n^{(r)}(N) = (1 - q)^{-n} & \text{if } r = 0\\ 0 & \text{else} \end{cases}
$$

Finally, by letting $N \to +\infty$ in the formula of Theorem [2.18](#page-15-0) and incorporating the result we just obtained, we get

$$
n\sum_{k=0}^{+\infty} q^{(r+1)k} [k]^{n-1} + (q-1)r \sum_{k=0}^{+\infty} q^{rk} [k]^n = \begin{cases} (1-q)^{-n} - \beta_n^{(r)} & \text{if } r=0\\ -\beta_n^{(r)} & \text{else} \end{cases}
$$

implying the desired result of the theorem and completes the proof.

Remark 2.20. For $r \in \mathbb{N}$, the formula of Theorem [2.19](#page-15-1) can be written more simply as:

$$
\beta_n^{(r)} = \sum_{k=0}^{+\infty} \left(r q^{rk} - (n+r) q^{(r+1)k} \right) [k]^{n-1}.
$$
 (2.23)

Taking in particular $r = 1$, we derive the following important representation of the Carlitz q-Bernoulli numbers as series:

$$
\beta_n = \sum_{k=0}^{+\infty} \left(q^k - (n+1)q^{2k} \right) [k]^{n-1}
$$
 (2.24)

(valid for $|q| < 1$ and $n \in \mathbb{N}$).

From Remark [2.20](#page-16-0) and the fact that the extended Carlitz q-Bernoulli numbers of any positive order are q-analogues of the classical Bernoulli numbers, we immediately derive the following corollary:

Corollary 2.21. For all $r, n \in \mathbb{N}$, we have that

$$
B_n = \lim_{q \to 1} \sum_{k=0}^{+\infty} \left(r q^{rk} - (n+r) q^{(r+1)k} \right) [k]^{n-1}.
$$

Remark 2.22*.* If, in the formula of Corollary [2.21,](#page-16-1) we allow the limit to be taken inside the sum and also permit the manipulation of divergent series, we obtain, for all $n \in \mathbb{N}$:

$$
B_n = \sum_{k=0}^{+\infty} -nk^{n-1} = -n \sum_{k=1}^{+\infty} k^{n-1} = -n\zeta(1-n).
$$

This provides a well-known and valid formula for the classical Bernoulli numbers, where ζ denotes the Riemann zeta function.

2.2.3 Expression of the $\beta_n^{(r)}$'s in terms of q-Stirling numbers of the second kind

The following theorem provides a generalization of Formula [\(1.8\)](#page-3-0) of Carlitz, which express the Carlitz q-Bernoulli numbers in terms of q -Stirling numbers of the second kind.

Theorem 2.23. *For all* $r \in \mathbb{N}$ *and* $n \in \mathbb{N}_0$ *, we have*

$$
\beta_n^{(r)} = \sum_{k=0}^n \varphi_r(q,k) S_q(n,k),
$$

where

$$
\varphi_r(q,k) = (-1)^k [k]! \sum_{i=0}^{r-1} q^{ik} \frac{[r-1]_i}{[k+r]_{i+1}}
$$

= $(-1)^k [k]! [r-1]! q^{-r+1} \sum_{i=0}^{r-1} \frac{(q-1)^i q^{\frac{1}{2}i(i+1)-i(r-1)}}{[r-1-i]!} \frac{1}{[k+i+1]}$

(for all $k \in \mathbb{N}$ *).*

The proof of this theorem needs some preparations which are presented below. We begin with the following proposition:

Proposition 2.24. *For all* $r, N \in \mathbb{N}$ *and* $k \in \mathbb{N}_0$ *, we have*

$$
\sum_{i=0}^{N-1} q^{ir} [i]_k = \left(\sum_{\ell=0}^{r-1} q^{(r-\ell-1)N + (\ell+1)k} \frac{[r-1]_{\ell}}{[k+r]_{\ell+1}} \right) [N]_{k+1}.
$$

Proof. Let $k \in \mathbb{N}_0$ and $N \in \mathbb{N}$ be fixed. For all $r \in \mathbb{N}$, we have

$$
\Delta (q^{(r-1)X}[X]_{k+1}) = q^{(r-1)(X+1)}[X+1]_{k+1} - q^{(r-1)X}[X]_{k+1}
$$

= $q^{(r-1)(X+1)}[X+1][X] \cdots [X-k+1] - q^{(r-1)X}[X][X-1] \cdots [X-k]$
= $(q^{(r-1)(X+1)}[X+1] - q^{(r-1)X}[X-k] [X]_k.$

 \Box

But since

$$
q^{(r-1)(X+1)}[X+1] - q^{(r-1)X}[X-k] = q^{(r-1)(X+1)}\frac{q^{X+1}-1}{q-1} - q^{(r-1)X}\frac{q^{X-k}-1}{q-1}
$$

$$
= \frac{q^{r(X+1)} - q^{(r-1)(X+1)} - q^{rX-k} + q^{(r-1)X}}{q-1}
$$

$$
= \frac{q^{rX-k}(q^{k+r}-1) - q^{(r-1)X}(q^{r-1}-1)}{q-1}
$$

$$
= q^{rX-k}[k+r] - q^{(r-1)X}[r-1],
$$

it follows that:

$$
\Delta (q^{(r-1)X}[X]_{k+1}) = (q^{rX-k}[k+r] - q^{(r-1)X}[r-1])[X]_{k}.
$$

By multiplying both sides of this last equality by $\frac{q^k}{k+1}$ $\frac{q^m}{[k+r]}$ and then summing both sides of the resulting equality from $X = 0$ to $N - 1$, we get (after simplifying and rearranging)

$$
\sum_{X=0}^{N-1} q^{rX} [X]_k = \frac{q^{(r-1)N+k}}{[k+r]} [N]_{k+1} + q^k \frac{[r-1]}{[k+r]} \sum_{X=0}^{N-1} q^{(r-1)X} [X]_k.
$$

By reiterating this last formula r times, we get

$$
\sum_{X=0}^{N-1} q^{rX} [X]_k = q^{(r-1)N+k} \frac{1}{[k+r]} [N]_{k+1} + q^{(r-2)N+2k} \frac{[r-1]}{[k+r][k+r-1]} [N]_{k+1}
$$

+ $q^{(r-3)N+3k} \frac{[r-1]_2}{[k+r]_3} [N]_{k+1} + \dots + q^{rk} \frac{[r-1]_{r-1}}{[k+r]_r} [N]_{k+1} + q^{rk} \frac{[r-1]_r}{[k+r]_r} \sum_{X=0}^{N-1} [X]_k$
= $\left(\sum_{\ell=0}^{r-1} q^{(r-\ell-1)N+(\ell+1)k} \frac{[r-1]_\ell}{[k+r]_{\ell+1}} \right) [N]_{k+1}$ (since $[r-1]_r = 0$).

The proposition is proved.

In what follows, for $r, N \in \mathbb{N}$ and $k \in \mathbb{N}_0$, we set

$$
f_r(q,k,N) := q^{\frac{k(k-1)}{2}} \sum_{i=0}^{N-1} q^{ir}[i]_k,
$$

which is q-polynomial in N (according to Proposition [2.24\)](#page-17-0). We let also $f_r(q, k, X)$ denote the unique q-polynomial interpolating $f_r(q, k, N)$ at the positive integers $X = N$, and $g_r(q, k)$ denote the limit:

$$
g_r(q, k) := \lim_{X \to 0} \frac{1}{[X]} f_r(q, k, X).
$$

A first useful expression for $g_r(q, k)$ is directly derived from Proposition [2.24.](#page-17-0) We have the following corollary:

Corollary 2.25. *For all* $r \in \mathbb{N}$ *and* $k \in \mathbb{N}_0$ *, we have*

$$
g_r(q,k) = (-1)^k [k]! \left(\sum_{i=0}^{r-1} q^{ik} \frac{[r-1]_i}{[k+r]_{i+1}} \right).
$$

Proof. Let $r \in \mathbb{N}$ and $k \in \mathbb{N}_0$ be fixed. According to Proposition [2.24,](#page-17-0) we have for all $N \in \mathbb{N}$:

$$
f_r(q,k,N) = q^{\frac{k(k-1)}{2}} \left(\sum_{\ell=0}^{r-1} q^{(r-\ell-1)N+(\ell+1)k} \frac{[r-1]_{\ell}}{[k+r]_{\ell+1}} \right) [N]_{k+1}.
$$

Hence

$$
f_r(q,k,X) = q^{\frac{k(k-1)}{2}} \left(\sum_{\ell=0}^{r-1} q^{(r-\ell-1)X + (\ell+1)k} \frac{[r-1]_{\ell}}{[k+r]_{\ell+1}} \right) [X]_{k+1}.
$$

Consequently, we have

$$
g_r(q,k) := \lim_{X \to 0} \frac{1}{[X]} f_r(q,k,X)
$$

\n
$$
= \lim_{X \to 0} q^{\frac{k(k-1)}{2}} \left(\sum_{\ell=0}^{r-1} q^{(r-\ell-1)X+(\ell+1)k} \frac{[r-1]_{\ell}}{[k+r]_{\ell+1}} \right) [X-1]_k
$$

\n
$$
= q^{\frac{k(k+1)}{2}} \left(\sum_{\ell=0}^{r-1} q^{\ell k} \frac{[r-1]_{\ell}}{[k+r]_{\ell+1}} \right) [-1]_k
$$

\n
$$
= (-1)^k [k]! \sum_{\ell=0}^{r-1} q^{\ell k} \frac{[r-1]_{\ell}}{[k+r]_{\ell+1}}
$$

(since $[-1]_k = (-1)^k q^{-\frac{k(k+1)}{2}}[k]!$). The corollary is proved.

An equally interesting formula for $g_r(q, k)$ $(r \in \mathbb{N}, k \in \mathbb{N}_0)$ can be derived by decomposing the q-rational function $\frac{q^{iX}}{[X]}$ $\frac{q^{i\alpha}}{[X]_{i+1}}$ $(0 \leq i \leq r-1)$ into q-partial fractions. This decomposition is given by the following proposition:

Proposition 2.26. *For all* $k \in \mathbb{N}_0$ *, we have*

$$
\frac{q^{kX}}{[X]_{k+1}} = \frac{1}{[k]!} \sum_{i=0}^{k} \left((-1)^{k-i} \binom{k}{i} q^{\frac{k^2+k}{2} + \frac{i^2-i}{2}} \frac{1}{[X-i]} \right).
$$

Proof. Let $k \in \mathbb{N}_0$ be fixed. We will first establish the existence and uniqueness of real numbers $\alpha_{k,i}(q)$ $(0 \leq i \leq k)$ such that the following holds:

$$
\frac{q^{kX}}{[X]_{k+1}} = \sum_{i=0}^{k} \frac{\alpha_{k,i}(q)}{[X-i]}.
$$
\n(2.25)

We have:

$$
(2.25) \iff q^{kX} = \sum_{i=0}^{k} \alpha_{k,i}(q) \frac{[X]_{k+1}}{[X-i]}
$$

$$
\iff q^{kX} = \sum_{i=0}^{k} \alpha_{k,i}(q) \left(\prod_{\substack{0 \le j \le k \\ j \ne i}} [X-j] \right).
$$
(2.26)

Consider the family $\mathscr B$ of $(k+1)$ q-polynomials of degree k given by:

$$
\mathscr{B} := \left\{ \prod_{\substack{0 \le j \le k \\ j \ne i}} [X - j] \right\}_{0 \le i \le k}.
$$

It can be observed that any k arbitrary q-polynomials from $\mathscr B$ always share a common root that is not a root of the remaining q-polynomial in \mathscr{B} . Therefore, no q-polynomial in \mathscr{B} can be expressed as a linear combination of the others, which shows that $\mathscr B$ is a linearly independent family in \mathscr{E}_k . Consequently, since Card $\mathscr{B} = \dim \mathscr{E}_k = k + 1$, \mathscr{B} is a basis of \mathscr{E}_k . It follows that the q-polynomial q^{kX} (belonging to \mathscr{E}_k) can be uniquely expressed as a linear combination of the q-polynomials in \mathscr{B} . This establishes the existence and uniqueness of real numbers $\alpha_{k,i}(q)$ $(0 \leq i \leq k)$ satisfying (2.26) (equivalently (2.25)).

Let us now determine the real numbers $\alpha_{k,i}(q)$ $(0 \leq i \leq k)$. For a given $\ell \in \{0, 1, \ldots, k\},$ by multiplying both sides of [\(2.25\)](#page-19-0) by $[X - \ell]$ and then substituting $X = \ell$ into the resulting identity, we obtain:

$$
\frac{q^{k\ell}}{[\ell][\ell-1]\cdots[1]\cdot[-1][-2]\cdots[\ell-k]} = \alpha_{k,\ell}(q).
$$
\n
$$
\frac{q^{k\ell}}{[\ell][\ell-1]\cdots[1]\cdot[1][-2]\cdots[\ell-k]} = \alpha_{k,\ell}(q).
$$

But since $[\ell][\ell-1]\cdots[1] = [\ell]!$ and $[-1][-2] \cdots [\ell-k] = (-1)^{k-\ell}q^{-1}$ $\frac{2}{2}$ $|k - \ell|!$ (using the property $[-X] = -q^{-X}[X]$, it follows that:

$$
\alpha_{k,\ell}(q) = \frac{(-1)^{k-\ell} q^{\frac{(k-\ell)(k-\ell+1)}{2} + k\ell}}{[\ell]![k-\ell]!}
$$

=
$$
\frac{1}{[k]!} (-1)^{k-\ell} {k \brack \ell} q^{\frac{k^2+k}{2} + \frac{\ell^2-\ell}{2}},
$$

as required. This completes the proof.

Using the formula from Proposition [2.26,](#page-19-2) the formula of Corollary [2.25](#page-18-0) for $g_r(q, k)$ can be transformed into another, more interesting form for studying the limiting case as $q \to 1$. We have the following proposition:

Proposition 2.27. *For all* $r \in \mathbb{N}$ *and* $k \in \mathbb{N}_0$ *, we have*

$$
g_r(q,k) = (-1)^k [k]![r-1]!q^{-r+1} \sum_{i=0}^{r-1} \frac{(q-1)^i q^{\frac{1}{2}i(i+1)-i(r-1)}}{[r-1-i]!} \frac{1}{[k+i+1]}.
$$

Proof. Let $r \in \mathbb{N}$ and $k \in \mathbb{N}_0$ be fixed. By successively applying Corollary [2.25](#page-18-0) and Proposition [2.26,](#page-19-2) we obtain

$$
g_r(q,k) = (-1)^k [k]! \sum_{i=0}^{r-1} q^{-ir} [r-1]_i \left\{ \frac{q^{i(k+r)}}{[k+r]_{i+1}} \right\}
$$

$$
= (-1)^k [k]! \sum_{i=0}^{r-1} q^{-ir} [r-1]_i \frac{1}{[i]!} \sum_{j=0}^i (-1)^{i-j} {i \choose j} q^{\frac{i^2+i}{2} + \frac{j^2-j}{2}} \frac{1}{[k+r-j]}
$$

$$
= (-1)^k [k]! \sum_{\substack{0 \le i \le r-1 \\ 0 \le j \le i}} q^{-ir} \frac{[r-1]_i}{[i]!} {i \choose j} (-1)^{i-j} q^{\frac{i^2+i}{2} + \frac{j^2-j}{2}} \frac{1}{[k+r-j]}.
$$

By inverting the summations over i and j and noting that $\frac{[r-1]_i}{[i]!}\left[\frac{i}{j}\right]$ $\begin{bmatrix} i \\ j \end{bmatrix} = \begin{bmatrix} r-1 \\ j \end{bmatrix}$ $\begin{bmatrix} 1 \\ j \end{bmatrix} \begin{bmatrix} r-1-j \\ i-j \end{bmatrix}$ $\begin{bmatrix} -1-j \\ i-j \end{bmatrix}$ and that $q^{-ir} \cdot q^{\frac{i^2+i}{2}+\frac{j^2-j}{2}} = q^{\frac{(i-j)^2+(i-j)}{2}-i(r-j)}$ (for all $0 \le i \le r-1$ and $0 \le j \le i$), we derive that:

$$
g_r(q,k) = (-1)^k [k]! \sum_{0 \le j \le r-1} \left(\sum_{i=j}^{r-1} \begin{bmatrix} r-1-j \\ i-j \end{bmatrix} (-1)^{i-j} q^{\frac{(i-j)^2 + (i-j)}{2} - i(r-j)} \right) \begin{bmatrix} r-1 \\ j \end{bmatrix} \frac{1}{[k+r-j]}.
$$

Then, performing the change of index $\ell = i - j$ in the inner summation gives

$$
g_r(q,k) = (-1)^k [k]! \sum_{0 \le j \le r-1} \left(\sum_{\ell=0}^{r-1-j} q^{\frac{\ell(\ell-1)}{2}} {r-1-j \choose \ell} \left(-q^{1-r+j} \right)^{\ell} \right) q^{j^2 - jr} {r-1 \brack j} \frac{1}{[k+r-j]}.
$$

But according to the Gauss binomial formula [\(1.2\)](#page-2-1), we have for all $j \in \{0, 1, \ldots, r - 1\}$:

$$
\sum_{\ell=0}^{r-1-j} q^{\frac{\ell(\ell-1)}{2}} {r-1-j \choose \ell} \left(-q^{1-r+j}\right)^{\ell} = \left(1-q^{1-r+j}\right) \left(1-q^{2-r+j}\right) \cdots \left(1-q^{-1}\right)
$$

$$
= q^{1-r+j} \left(q^{r-1-j}-1\right) \cdot q^{2-r+j} \left(q^{r-2-j}-1\right) \cdots q^{-1} (q-1)
$$

$$
= q^{-\frac{(r-1-j)(r-j)}{2}} (q-1)^{r-1-j} [r-1-j]!.
$$

Substituting this into the last obtained expression for $g_r(q, k)$, we get

$$
g_r(q,k) = (-1)^k [k]! \sum_{j=0}^{r-1} q^{-\frac{(r-1-j)(r-j)}{2}} (q-1)^{r-1-j} [r-1-j]! q^{j^2-jr} \binom{r-1}{j} \frac{1}{[k+r-j]}.
$$

Finally, changing the index $i = r - 1 - j$ and rearranging yields

$$
g_r(q,k) = (-1)^k [k]![r-1]!q^{-r+1} \sum_{i=0}^{r-1} \frac{(q-1)^i q^{\frac{1}{2}i(i+1)-i(r-1)}}{[r-1-i]!} \frac{1}{[k+i+1]},
$$

as required.

We are now ready to prove Theorem [2.23.](#page-17-1)

Proof of Theorem [2.23.](#page-17-1) Let $r \in \mathbb{N}$ and $n \in \mathbb{N}_0$ be fixed. In view of Corollary [2.25](#page-18-0) and Proposition [2.27,](#page-20-0) we need to show that:

$$
\beta_n^{(r)} = \sum_{k=0}^n g_r(q, k) S_q(n, k).
$$

To achieve this, consider $N \in \mathbb{N}$ and evaluate the sum

$$
\sum_{i=0}^{N-1}q^{ri}[i]^n
$$

in two different ways. On the one hand, from Theorem [2.6,](#page-7-0) we have

$$
\sum_{i=0}^{N-1} q^{ri}[i]^n = q^{rN} S_n(N) - S_n(0),
$$

where $(S_k(X))_{k\in\mathbb{N}_0}$ is the Carlitz-type q-polynomial sequence associated to the real sequence of general term $a_k := \frac{1}{q-1}$ 1 $\frac{1}{[k+r]}$ ($\forall k \in \mathbb{N}_0$). So, putting $s_k := S_k(0)$ ($\forall k \in \mathbb{N}_0$) and using the formula of Theorem [2.2](#page-4-0) for $S_k(X)$, we derive that:

$$
\sum_{i=0}^{N-1} q^{ri}[i]^n = q^{rN} \sum_{k=0}^n \binom{n}{k} s_k q^{kN} [N]^{n-k} - s_n
$$

=
$$
\sum_{k=0}^{n-1} \binom{n}{k} s_k q^{(k+r)N} [N]^{n-k} + \left(q^{(n+r)N} - 1 \right) s_n.
$$
 (2.27)

On the other hand, by using Formula [\(1.7\)](#page-3-1), we have that:

$$
\sum_{i=0}^{N-1} q^{ri}[i]^n = \sum_{i=0}^{N-1} q^{ri} \left(\sum_{k=0}^n q^{\frac{1}{2}k(k-1)} S_q(n,k)[i]_k \right)
$$

=
$$
\sum_{k=0}^n S_q(n,k) \left(q^{\frac{1}{2}k(k-1)} \sum_{i=0}^{N-1} q^{ri}[i]_k \right)
$$

=
$$
\sum_{k=0}^n S_q(n,k) f_r(q,k,N).
$$
 (2.28)

Comparing [\(2.27\)](#page-22-0) and [\(2.28\)](#page-22-1), we derive the identity:

$$
\sum_{k=0}^{n-1} \binom{n}{k} s_k q^{(k+r)N} [N]^{n-k} + \left(q^{(n+r)N} - 1 \right) s_n = \sum_{k=0}^{n} S_q(n,k) f_r(q,k,N).
$$

Since this identity consists of q-polynomials in N and it is valid for all $N \in \mathbb{N}$ then it extends as a q-polynomial identity. Namely, we have

$$
\sum_{k=0}^{n-1} {n \choose k} s_k q^{(k+r)X} [X]^{n-k} + (q^{(n+r)X} - 1) s_n = \sum_{k=0}^{n} S_q(n,k) f_r(q,k,X).
$$

Dividing through by $[X]$ and letting $X \to 0$, we derive

$$
ns_{n-1} + (q-1)(n+r)s_n = \sum_{k=0}^{n} g_r(q,k)S_q(n,k).
$$
 (2.29)

Now, setting for all $k \in \mathbb{N}_0$:

$$
T_k(X) := kS_{k-1}(X) + (q-1)(k+r)S_k(X)
$$

= $(q-1)rS_k(X) + k(S_{k-1}(X) + (q-1)S_k(X)),$

it is clear that $ns_{n-1} + (q-1)(n+r)s_n = T_n(0)$. Next, the q-polynomial sequence $((q-1) r S_k(X))_{k \in \mathbb{N}_0}$ is clearly Carlitz-type with associated real sequence $((q-1) r a_k)_k = \left(\frac{r}{|k|^2}\right)^{k}$ $\frac{r}{[k+r]}$ k . Besides, according to Item 4 of Proposition [2.11,](#page-10-1) the q-polynomial sequence $(k(S_{k-1}(X) + (q-1)S_k(X)))_{k \in \mathbb{N}_0}$ is also Carlitz-type with associated real sequence $((q-1)ka_k)_k = \left(\frac{k}{|k|}\right)$ $\frac{k}{[k+r]}$. Consequently, the q-polynomial sequence $(T_k(X))_{k \in \mathbb{N}_0}$ is Carlitz-type with associated real sequence $\left(\frac{r}{|k+1|}\right)$ $\frac{r}{[k+r]}$ $_{k}+\left(\frac{k}{\left[k\right] }% \frac{m}{k}\right) ^{k}$ $\frac{k}{[k+r]}$ $\frac{k}{k} = \left(\frac{k+r}{[k+r]}\right)$ $\frac{k+r}{[k+r]}$. Thus $(T_k(X))_k$ coincides with

 \Box

 $\left(\beta_k^{(r)}\right)$ $\binom{(r)}{k}(X)$ _k, that is $T_k(X) = \beta_k^{(r)}$ $k_k^{(r)}(X)$ ($\forall k \in \mathbb{N}_0$). In particular, we have $ns_{n-1}+(q-1)(n+r)s_n =$ $T_n(0) = \beta_n^{(r)}(0) = \beta_n^{(r)}$. Substituting this into [\(2.29\)](#page-22-2) yields the required formula. This completes the proof. \Box

From Theorem [2.23,](#page-17-1) we derive the following curious corollary:

Corollary 2.28. For all $n \in \mathbb{N}_0$, we have

$$
\beta_n + q\beta_{n+1} = \sum_{k=0}^n (-1)^k \frac{[k]!}{[k+2]} S_q(n,k).
$$

Proof. Let $n \in \mathbb{N}_0$ be fixed. According to Formula [\(2.17\)](#page-13-4), we have

$$
\beta_n^{(2)} = \beta_n^{(1)} + (q-1)\beta_{n+1}^{(1)} = \beta_n + (q-1)\beta_{n+1},
$$

which gives $\beta_{n+1} = \frac{\beta_n^{(2)} - \beta_n}{a-1}$ $\frac{q^{n}-\beta_n}{q-1}$, and then

$$
\beta_n + q\beta_{n+1} = \beta_n + q \left(\frac{\beta_n^{(2)} - \beta_n}{q - 1} \right) = \frac{q\beta_n^{(2)} - \beta_n^{(1)}}{q - 1}
$$

It follows by using Theorem [2.23](#page-17-1) that

$$
\beta_n + q\beta_{n+1} = \sum_{k=0}^n \frac{q\varphi_2(q, k) - \varphi_1(q, k)}{q - 1} S_q(n, k).
$$
 (2.30)

.

Further, from the second expression of $\varphi_r(q, k)$ in Theorem [2.23,](#page-17-1) we have that

$$
\varphi_1(q,k) = (-1)^k \frac{[k]!}{[k+1]}
$$
 and $\varphi_2(q,k) = (-1)^k [k]! q^{-1} \left(\frac{1}{[k+1]} + \frac{q-1}{[k+2]} \right).$

Thus

$$
\frac{q\varphi_2(q,k) - \varphi_1(q,k)}{q-1} = (-1)^k \frac{[k]!}{[k+2]}.
$$

Substituting this into [\(2.30\)](#page-23-1) yields the required formula. This achieves the proof.

Letting $q \rightarrow 1$ in Corollary [2.28](#page-22-3) gives the following result on the classical Bernoulli numbers, which is very recently pointed out by the author [\[4,](#page-24-1) Page 12, Formula (2.3)]:

Corollary 2.29. *For all* $n \in \mathbb{N}_0$ *, we have*

$$
B_n + B_{n+1} = \sum_{k=0}^n (-1)^k \frac{k!}{k+2} S(n,k).
$$
