Abstract

We give estimates for positive solutions for the Schrödinger equation $(\Delta_{\mu}+W)u=0$ on a wide class of parabolic weighted manifolds $(M, d\mu)$ when W decays to zero at infinity faster than quadratically. These can be combined with results of Grigor'yan [\[11\]](#page-28-0) to give matching upper and lower bounds for the heat kernel of the corresponding Schrödinger operator $\Delta_{\mu}+W$. In particular, this appears to complement known results for Schrödinger operators on \mathbb{R}^2 .

1 Introduction

We are interested in estimating the heat kernel for operators of the form $\Delta_{\mu} + W$, where Δ_{μ} is the Laplacian of a weighted manifold $(M, d\mu)$ and W is a function that decays faster than quadratically at infinity. We state our results on parabolic manifolds satisfying the parabolic Harnack inequality, a connectivity of annuli condition and a mild condition on volume growth. Notably our main result Theorem [6.4](#page-20-0) appears to give an addition to known results on \mathbb{R}^2 ; see Corollary [7.2.](#page-22-0)

1.1 Notation

For $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$ we let $|x| = \left(\sum_{j=1}^n x_j^2\right)$ $\int_{0}^{1/2}$ denote the norm of x. For a Riemannian manifold M we let $d(x, y)$ denote the geodesic distance between $x, y \in M$. When M has a distinguished point $o \in M$, we let $|x| = d(x, o)$ and $\langle x \rangle = 2 + |x|$.

We let $a \preceq b$ denote the existence of a constant $C > 0$ such that $a \leq C \cdot b$. We let $a \preceq b$ denote that both $a \leq b$ and $a \geq b$ hold. Exact constants may sometimes change line to line. Given a number $a \in \mathbf{R}$ we let $a_+ = \max(a, 0)$ and $a_- = \max(-a, 0)$. Given a real valued

function f we let $f_+ = \max(f, 0)$ and $f_- = \max(-f, 0)$ so that $f_+, f_- \ge 0$ and $f = f_+ - f_-.$ Given a smooth manifold M we let

> $C^{\infty}(M) = \{f : M \to \mathbf{R} \text{ smooth}\}\$ $C_c^{\infty}(M) = \{f \in C^{\infty}(M): f \text{ has compact support}\}\$ $C_0^{\infty}(M) = \{f \in C^{\infty}(M) : f \text{ vanishes at infinity}\}.$

Given a Borel measure $d\mu$ on a Riemannian manifold M, we let $B(x, r)$ and $\overline{B}(x, r)$ denote the open and closed geodesic balls of center $x \in M$ and radius $r > 0$ respectively. We let $V_\mu(x,r) = \mu(B(x,r))$. If M has a distinguished point $o \in M$, then we let $V_\mu(r)$ denote $V_\mu(o,r)$.

1.2 Background and Overview

The problem of estimating the heat kernel of $\Delta + W$ for various functions W has attracted considerable research interest. Aizenman and Simon in [\[1\]](#page-27-0) studied Harnack inequalities for Schrödinger operators and proved some heat kernel estimates in well-behaved bounded sets with Dirichlet boundary conditions. Due to the useful concept of Green-boundedness, which we will discuss below in Definition [4.1,](#page-11-0) many heat kernel estimates for Schrödinger operators have been obtained on manifolds that are non-parabolic, see Definition [1.4.](#page-3-0) See for example the papers by Takeda [\[27\]](#page-29-0), Devyver [\[7\]](#page-28-1), and Chen and Wang [\[2\]](#page-27-1) for results on heat kernels of Schrödinger operators on non-parabolic manifolds. See Davies and Simon [\[6\]](#page-28-2) and Zhang $[28]$, $[29]$ for results on Schrödinger operators with potentials that decay exactly quadratically. Fraas, Krejčiřík, and Pinchover in [\[8\]](#page-28-3) studied asymptotics of ratios of heat kernels for both subcritical and critical Schrödinger operators. Grigor'yan in [\[11\]](#page-28-0) obtained results for the heat kernel of a Schrödinger operator whose potential is positive and compactly supported on a parabolic manifold. Shen in [\[25\]](#page-29-3) studied the Green's functions of Schrödinger operators in \mathbb{R}^n , $n \geq 3$. Murata in [\[14\]](#page-28-4) and [\[16\]](#page-28-5) obtained large-time asymptotics for heat kernels of subcritical Schrödinger operators on Euclidean spaces including \mathbb{R}^2 .

Of particular relevance is the following result of Murata. See [1.7](#page-3-1) for the definition of the profile and [5.1](#page-14-0) for the definition of subcritical and critical. Here we let $\langle x \rangle = 2 + |x|$.

Theorem 1.1. (Murata [\[15\]](#page-28-6)) Let W be such that $\langle x \rangle^{\alpha-\frac{2}{p}} |W(x)| \in L^p(\mathbf{R}^2, dx)$ for $p > 1$, $\alpha > 2$. Then if $\Delta + W$ is subcritical, the profile $h > 0$ for $\Delta + W$ satisfies

$$
h(x) \asymp \log \langle x \rangle.
$$

If $\Delta + W$ is critical, the profile $h > 0$ for $\Delta + W$ satisfies

$$
h(x) \asymp 1.
$$

See also Murata [\[17\]](#page-28-7). The result below is a product of combining Murata's theorem above with Theorem 10.10 in Grigor'yan [\[11\]](#page-28-0).

Theorem 1.2. Let $W \in C^{\infty}(\mathbb{R}^2)$ be such that $\langle x \rangle^{\alpha - \frac{2}{p}} |W(x)| \in L^p(\mathbb{R}^2, dx)$ for $p > 1$, $\alpha > 2$. Let $p^{W}(t, x, y)$ denote the heat kernel of $\Delta + W$. There exist constants $c_1, c_2, c_3, c_4 > 0$ such that:

(i) If $\Delta + W$ is subcritical, then for all $t > 0$, $x, y \in \mathbb{R}^2$,

$$
\frac{c_1 \log \langle x \rangle \log \langle y \rangle}{t \log(\langle x \rangle + \sqrt{t}) \log(\langle y \rangle + \sqrt{t})} e^{-c_2 \frac{|x-y|^2}{t}} \le p^W(t, x, y) \le \frac{c_3 \log \langle x \rangle \log \langle y \rangle}{t \log(\langle x \rangle + \sqrt{t}) \log(\langle y \rangle + \sqrt{t})} e^{-c_4 \frac{|x-y|^2}{t}}.
$$

(ii) If $\Delta + W$ is critical, then for all $t > 0$, $x, y \in \mathbb{R}^2$,

$$
\frac{c_1}{t}e^{-c_2\frac{|x-y|^2}{t}} \le p^W(t,x,y) \le \frac{c_3}{t}e^{-c_4\frac{|x-y|^2}{t}}.
$$

In this paper we study Schrödinger operators whose potentials are smooth and vanish at infinity, and in that context give a result analogous to Murata's for a wide class of parabolic weighted manifolds. This can be then combined with Grigor'yan's theorem to give heat kernel estimates, although provide our own proof of this in Theorem [6.4.](#page-20-0) Looking back to \mathbb{R}^2 , our main result offers an addition to Theorem [1.2](#page-2-0) by including those $W \in C_0^{\infty}(\mathbb{R}^2)$ for which $\log \langle x \rangle |W(x)| \in L^1(\mathbf{R}^2, dx)$.

1.3 Setting: Weighted Manifolds

Definition 1.3. A weighted manifold (also called a manifold with density) is a pair $(M, d\mu)$ where M is a Riemannian manifold without boundary and $d\mu$ is a Borel measure on M that has a smooth positive density with respect to canonical Riemannian volume measure on M.

Given a smooth function f on M, let ∇f denote the gradient of f on M. Note that ∇f is defined using only f and the Riemannian metric, and is therefore independent of any choice of weighted measure on M. We define \mathcal{F}_{μ} to be the completion of $C_c^{\infty}(M)$ under the norm

$$
||f||_{\mathcal{E}^{1}} = \int_{M} |f|^{2} d\mu + \int_{M} |\nabla f|^{2} d\mu.
$$

There exists a (minimal) operator Δ_{μ} called the **Laplacian** of $(M, d\mu)$ such that whenever $f, g \in C_c^{\infty}(M)$,

$$
\int_M \langle \nabla f, \nabla g \rangle \, d\mu = \int_M f \Delta_\mu(g) d\mu.
$$

Here $\langle \cdot, \cdot \rangle$ is the Riemannian inner product.

Remark: We take the convention that $\Delta_{\mu} \geq 0$, so that e.g. on \mathbb{R}^{n} with the Euclidean metric and $d\mu$ = Lebesgue measure, we have $\Delta_{\mu} = -\sum_{j=1}^{n}$ ∂^2 $\frac{\partial^2}{\partial x_j^2}$.

Continuing, the quadratic form

$$
\mathcal{E}_{\mu}(f,f) = \int_M |\nabla f|^2 d\mu \tag{1.1}
$$

is a strictly local Dirichlet form on $L^2(M, d\mu)$ with domain \mathcal{F}_{μ} . This Dirichlet form has infinitesimal generator Δ_{μ} . We have the associated heat semigroup $e^{-t\Delta_{\mu}}$ and ensuing heat kernel $p_{\mu}(t, x, y)$, which is a fundamental solution of the heat equation $(\partial_t + \Delta_{\mu})u = 0$.

Definition 1.4. Let $(M, d\mu)$ be a complete, non-compact weighted manifold and let $p_{\mu}(t, x, y)$ be its heat kernel. If there exist $x, y \in M$ distinct such that

$$
\int_0^\infty p_\mu(t, x, y) dt = +\infty,
$$

we say $(M, d\mu)$ is **parabolic**. Otherwise we say $(M, d\mu)$ is **non-parabolic**.

For example, (\mathbf{R}^n, dx) is parabolic for $n = 1, 2$ and non-parabolic for $n \geq 3$.

Definition 1.5. Let $(M, d\mu)$ be a complete, non-compact, non-parabolic weighted manifold. The **Green's function** G_{μ} of $(M, d\mu)$ is defined as follows: for $x, y \in M$ distinct,

$$
G_{\mu}(x,y) = \int_0^{\infty} p_{\mu}(t,x,y)dt.
$$

The Green's function is the fundamental solution of Δ_{μ} , and for each $x \in M$, the function $G_{\mu}(x, \cdot)$ is Δ_{μ} -harmonic on $M \setminus \{x\}$, which we define below.

Definition 1.6. Let $\Omega \subseteq M$ be open and let u be a smooth function on Ω . We say that u is Δ_{μ} -harmonic on Ω if

$$
\Delta_{\mu}u=0.
$$

We say that u is Δ_{μ} -subharmonic (resp. Δ_{μ} -superharmonic) on Ω if

$$
\Delta_{\mu} u \le 0 \quad \text{(resp. } \Delta_{\mu} u \ge 0\text{)}.
$$

Definition 1.7. Let $(M, d\mu)$ be a complete, non-compact weighted manifold and let $W \in$ $C^{\infty}(M)$. A **profile** for $\Delta_{\mu} + W$ is a positive smooth function $h > 0$ satisfying

$$
(\Delta_{\mu} + W)h = 0.
$$

Definition 1.8. Let $(M, d\mu)$ be a complete, non-compact weighted manifold and let $W \in$ $C^{\infty}(M)$. We say that $\Delta_{\mu} + W \geq 0$ if for all $\varphi \in C^{\infty}_c(M)$ we have

$$
\int_M \varphi(\Delta_\mu + W) \varphi d\mu \ge 0.
$$

We finish this section by citing two useful classical results.

Theorem 1.9. (Allegretto-Piepenbrink Theorem) Let $(M, d\mu)$ be a complete, non-compact weighted manifold and let $W \in C^{\infty}(M)$ be bounded. Then $\Delta_{\mu} + W \ge 0$ if and only if there exists a profile for $\Delta_{\mu} + W$.

Proof: See e.g. the book by Pigola, Rigoli, and Setti [\[19\]](#page-28-8), Lemma 3.10 for unweighted manifolds. The proof for weighted manifolds is the same. \Box

Theorem 1.10. (Liouville's Theorem) Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold. Let $u > 0$ be a positive Δ_{μ} -superharmonic function on M. Then u is constant.

Proof: See e.g. Grigor'yan [\[10\]](#page-28-9) Theorem 5.1 for the case when M is unweighted, or Sturm [\[26\]](#page-29-4) Theorem 3 for a more general version in a strictly local recurrent Dirichlet space. \Box

2 Parabolic Manifolds and Harmonic Functions Outside a Ball

Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold. Let d denote geodesic distance on M. We let $B(x, r)$ denote the ball of radius $r > 0$ and center $x \in M$, and furthermore let $V_\mu(x,r) = \mu(B(x,r))$. When M has a distinguished point o, we let $V_\mu(r)$ $V_\mu(o,r)$.

Definition 2.1. We say that a Riemannian manifold M satisfies the **relatively connected annuli (RCA)** property with respect to $o \in M$ if there exists $A > 1$ such that for all $x, y \in M$ and all $R > 0$, if $d(x, o) = d(y, o) = R$, there exists a continuous path from x to y in the annulus $B(o, AR) \setminus B(o, A^{-1}R)$.

For example, \mathbb{R}^2 satisfies (RCA) with respect to the origin (or any point), and \mathbb{R} fails to satisfy (RCA). A connected sum of two Euclidean spaces fails to satisfy (RCA) with respect to any point.

Definition 2.2. We say that a complete, non-compact weighted manifold $(M, d\mu)$ satisfies **Gaussian-type heat kernel estimates (HKE)** if there exist constants $c_1, c_2, c_3, c_4 > 0$ such that for all $t > 0$ and all $x, y \in M$ we have

$$
\frac{c_1}{V_\mu(x,\sqrt{t})} \exp\left(-c_2 \frac{d(x,y)^2}{t}\right) \le p_\mu(t,x,y) \le \frac{c_3}{V_\mu(x,\sqrt{t})} \exp\left(-c_4 \frac{d(x,y)^2}{t}\right). \tag{2.1}
$$

Here $p_{\mu}(t, x, y)$ is the heat kernel of $(M, d\mu)$ and $V_{\mu}(x, r) = \mu(B(x, r)).$

The property (HKE) has wide-ranging implications, some of which we will discuss in [2.6.](#page-5-0) An application to Green's functions that will be particularly useful to us is stated below.

Lemma 2.3. Let $(M, d\mu)$ be a complete, non-compact weighted manifold satisfying (HKE). Then the Green's function $G_{\mu}(x, y)$ of $(M, d\mu)$ satisfies

$$
G_{\mu}(x,y) \asymp \int_{d(x,y)^2}^{\infty} \frac{dt}{V_{\mu}(x,\sqrt{t})}.
$$
\n(2.2)

Proof: See e.g. Saloff-Coste [\[24\]](#page-29-5), Corollary 5.4.13.

Now consider the following two properties.

Definition 2.4. A weighted manifold $(M, d\mu)$ satisfies **volume doubling (VD)** if there exists a constant $C_{VD} > 0$ such that for all $x \in M$ and $r > 0$, $\mu(B(x, 2r)) \leq C\mu(B(x, r))$.

Definition 2.5. A weighted manifold $(M, d\mu)$ satisfies the **Poincaré inequality (PI)** if there exist constants C_P , $A_P > 0$ such that for all $x \in M$, $r > 0$, and for all $f \in$ $C^1(B(x, A_P r))$, we have

$$
\int_{B(x,r)} |f - f_{B(x,r)}|^2 d\mu \le C_P r^2 \int_{B(x,Ar)} |\nabla f|^2 d\mu.
$$
\n(2.3)

Here $f_B = \frac{1}{\mu}$ $\frac{1}{\mu(B)}\int_B f d\mu.$ \Box

We now state an important theorem connecting (HKE) to (VD) and (PI).

Theorem 2.6. (Grigor'yan [\[9\]](#page-28-10), Saloff-Coste [\[23\]](#page-29-6)) Let $(M, d\mu)$ be a complete, non-compact weighted Riemannian manifold. Then $(M, d\mu)$ satisfies (HKE) if and only if $(M, d\mu)$ satisfies (VD) and (PI) .

In practice, (VD) and (PI) are often easier to check than (HKE). Gaussian-type heat kernel estimates imply a wide array of properties, including the parabolic Harnack inequality. The parabolic Harnack inequality, which is actually equivalent to (HKE), then implies the (scale-invariant) elliptic Harnack inequality, which we state now.

Lemma 2.7. Let $(M, d\mu)$ be a complete, non-compact weighted manifold satisfying (HKE). There exists a constant $C_H > 0$ such that for any open ball $B = B(x,r)$ in M and any positive Δ_{μ} -harmonic function $u > 0$ on $2B = B(x, 2r)$, we have

$$
\sup_B u \le C_H \inf_B u.
$$

Proof: See e.g. Saloff-Coste [\[23\]](#page-29-6) Theorem 3.1.

The conclusion of the following classical lemma is known as the metric doubling property.

Lemma 2.8. Assume that $(M, d\mu)$ is a complete, non-compact, weighted manifold satisfying (VD). There exists $N \in \mathbb{N}$ such that for all $x \in M$ and all $R > 0$, the ball $B(x, R)$ of radius R and center x can be covered by at most N balls of radius at most $R/2$.

Proof: See e.g. the book by Coifman and Weiss [\[5\]](#page-28-11), pages 67-68.

The above lemma can be combined with the scale-invariant elliptic Harnack inequality to produce the following radial version of the Harnack inequality.

Lemma 2.9. Assume that $(M, d\mu)$ is a complete, non-compact, weighted manifold satisfying (HKE) and (RCA) with respect to $o \in M$. Let $A > 0$ be the constant appearing the definition of (RCA). Let $R > 0$ and let $u > 0$ be Δ_{μ} -harmonic on $B(o, 2AR) \setminus \overline{B}(o,(2A)^{-1}R)$. Then there exists $C > 0$ independent of R such that if $d(x, o) = d(y, o)$, then $u(x) \leq Cu(y)$.

Proof: By iterating Lemma [2.8,](#page-5-1) we get $N \in \mathbb{N}$ such that for any $R > 0$ and any $x \in M$, the ball $B(x, R)$ can be covered in N balls of radius at most $R/16A^2$. Now fix $R > 0$ and cover the ball of radius $B(o, 2AR)$ with N balls of radius $R/8A$. Note that if B is such a ball that meets $B(o, AR) \setminus \overline{B}(o, A^{-1}R)$, then 2B lies in $B(o, 2AR) \setminus \overline{B}(o,(2A)^{-1}R)$.

Let x and y be such that $d(x, o) = d(y, o) = R$. By (RCA), there exists a continuous path from x to y in $B(o, A) \setminus B(o, A^{-1}R)$. By the previous, our path is covered by at most N balls B such that $2B \subseteq B(o, 2A) \setminus \overline{B}(o,(2A)^{-1}R)$. By Lemma [2.7,](#page-5-2) there exists a constant $C_H > 0$ independent of R such that for each such ball B we have

$$
\sup_B u \le C_H \inf_B u. \tag{2.4}
$$

 \Box

 \Box

Therefore by applying the [2.4](#page-5-3) to each of the balls covering the path without repetition, we obtain the desired result, namely that $u(x) \leq (C_H)^N u(y)$. \Box

Let $(M, d\mu)$ be a weighted manifold with distinguished point $o \in M$. For $r > 0$ let $V_{\mu}(r) = V_{\mu}(o, r)$ be the volume of the ball $B(o, r)$. Given $x \in M$ we set $|x| := d(x, o)$.

Let us define

$$
H(r) := 1 + \left(\int_1^{r^2} \frac{ds}{V_\mu(\sqrt{s})}\right)_+.
$$
\n(2.5)

Note that

$$
H(r) \asymp 1 + \left(\int_1^r \frac{s}{V_\mu(s)} ds\right)_+ \asymp \int_0^r \frac{s e^{-1/s}}{V_\mu(s)} ds.
$$

We wish to study positive functions that are harmonic outside a neighborhood of o . We have the following result due to Grigory'an and Saloff-Coste [\[12\]](#page-28-12):

Proposition 2.10. Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) with respect to $o \in M$. Let K be compact with nonempty interior and $o \in K$. There exists a positive smooth function u on M which is Δ_{μ} -harmonic in $M \setminus K$ and satisfies

$$
u(x) \asymp H(|x|) \tag{2.6}
$$

for all $x \in M$.

Note that because M is parabolic, $H(|x|) \to +\infty$ as $|x| \to \infty$.

We now introduce a potential q , which we will require to be well-behaved: namely smooth, nonnegative, and compactly supported. Profiles, defined in [1.7](#page-3-1) as positive solutions $h > 0$ to $(\Delta_{\mu} + q)h = 0$ will be highly important to our main results.

Lemma 2.11. Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) with respect to $o \in M$. Let $q \in C_c^{\infty}(M)$ be non-negative and not identically zero. Let $h > 0$ satisfy $(\Delta_{\mu} + q)h = 0$. Then

$$
h(x) \asymp H(|x|).
$$

Proof: Let $A > 0$ be as in the definition of (RCA) and let $h > 0$ be a profile for $\Delta_{\mu} + q$ as in the hypothesis. For $x \in M$ let $|x| = d(x, o)$. Let $R_0 > 0$ be such that $B(o, (2A)^{-1}R_0)$ contains the support of q. Let $K = \overline{B}(o,(2A)^{-1}R_0)$. Note that h is Δ_μ -harmonic in $M \setminus K$.

As in Proposition [2.10,](#page-6-0) let $u > 0$ be smooth on M that is Δ_{μ} -harmonic in $M \backslash K$ such that $u(x) \approx H(|x|)$ for all $x \in M$. By Lemma [2.9,](#page-5-4) there exists $C > 0$ such that if $|x| = |y| > R_0$, then $u(x) \leq Cu(y)$, and similarly for h. With this in mind for $r > 0$ and a function f on M we define $f(r) = \sup_{|x|=r} f(x)$.

It suffices to show that $h(x) \simeq u(x)$. Since $(\Delta_{\mu} + q)h = 0$, h is non-constant. Moreover we have $\Delta_{\mu}h = -qh \leq 0$ and so h is Δ_{μ} -subharmonic. If h were bounded, then for some $D > 0$, $D - h$ would be a positive Δ_{μ} -superharmonic function in M which contradicts Liouville's Theorem [1.10.](#page-3-2) So h is unbounded and in particular $\limsup_{r\to\infty} h(r) = +\infty$.

We can thus choose $\epsilon > 0$ sufficiently small so that for some $R > R_0$, $(h - \epsilon u)(R) >$ $(h - \epsilon u)(R_0) > 0$. By the maximum principle, we get that $(h - \epsilon u)(r) \ge (h - \epsilon u)(R)$ for all $r > R$. Thus if $|x| > R$, then let y be such that $|y| = |x|$ and $(h - \epsilon u)(y) = (h - \epsilon u)(r)$. By Harnack's inequality [2.9](#page-5-4) we have that $u(x) \leq Cu(y) \leq \frac{C}{\epsilon}$ $\frac{C}{\epsilon}h(y) \leq \frac{C^2}{\epsilon}$ $\frac{\partial^2}{\partial \epsilon}h(x)$. Thus we have $u \preceq h$ outside a compact set. This implies $u \preceq h$ on all of M.

Since all we needed for this argument was h and u to be positive, unbounded, and Δ_{μ} harmonic in $M \setminus K$, we can repeat this argument with h and u switched, yielding $h \simeq u$. \Box

3 Doob's h-transform

Let $(M, d\mu)$ be a weighted manifold with Laplacian Δ_{μ} . Let $W \in C^{\infty}(M)$ be bounded. Consider the Schrödinger form on M given by

$$
\mathcal{E}_{\mu}^{W}(f,f) = \int_{M} |\nabla f|^{2} d\mu + \int_{M} W |f|^{2} d\mu \qquad (3.1)
$$

with domain \mathcal{F}_{μ} , the same as that of \mathcal{E}_{μ} from [1.1.](#page-2-1) Assume there exists a profile $h > 0$ for $\Delta_{\mu} + W$ and let $d\nu = h^2 d\mu$. Consider the weighted manifold $(M, d\nu)$ with strictly local Dirichlet form

$$
\mathcal{E}_{\nu}(f,f) = \int_M |\nabla f|^2 \, d\nu. \tag{3.2}
$$

We can contexualize this in terms of the unitary operator $\mathfrak{u}_h : L^2(M, h^2 d\mu) \to L^2(M, d\mu)$ given by $\mathfrak{u}_h(f) = hf$. Integration by parts and the fact that h is a profile for $\Delta_\mu + W$ imply that

$$
\mathcal{E}_{\nu}(f,f) = \mathcal{E}_{\mu}^{W}(\mathfrak{u}_{h}(f),\mathfrak{u}_{h}(f))
$$
\n(3.3)

for $f \in C_c^{\infty}(M)$. This suggests defining the domain of \mathcal{E}_{ν} as $\mathcal{F}_{\nu} = \mathfrak{u}_h^{-1} \mathcal{F}_{\mu}$.

Let $d\nu = h^2 d\mu$. By Equation [3.3,](#page-7-0) the Laplacian of the weighted manifold $(M, d\nu)$ is related to that of $(M, d\mu)$ by $\Delta_{\nu}(f) = \frac{1}{h}(\Delta_{\mu} + W)(hf)$, i.e. $\Delta_{\nu} = \mathfrak{u}_h^{-1} \circ (\Delta_{\mu} + W) \circ \mathfrak{u}_h$. Let $p_{\nu}(t, x, y)$ denote the heat kernel of Δ_{ν} . One can verify that $p_{\nu}(t, x, y)$ is related to the heat kernel $p_{\mu}^{W}(t,x,y)$ of $\Delta_{\mu} + W$ via

$$
p_{\mu}^{W}(t,x,y) = h(x)h(y)p_{\nu}(t,x,y).
$$
\n(3.4)

Thus, an estimate of $p_{\nu}(t, x, y)$ together with an estimate of h yield an estimate of $p_{\mu}^{W}(t, x, y)$.

3.1 Iterated h-Transform

In this section we discuss the iterated h-transform.

Lemma 3.1. Let $(M, d\mu)$ be a weighted manifold and let $W_1, W_2 \in C^{\infty}(M)$. Let $g, h > 0$ be positive functions on M satisfying $(\Delta_{\mu} + W_1)h = 0$ and $(\Delta_{\nu} + W_2)g = 0$, where $d\nu = h^2 d\mu$. Then letting $d\theta = g^2 h^2 d\mu$, if $p_{\mu}^{W_1+W_2}(t,x,y)$ denotes the heat kernel of $\Delta_{\mu} + W_1 + W_2$ on $(M, d\mu)$ and $p_{\theta}(t, x, y)$ denotes the heat kernel of Δ_{θ} on $(M, d\theta)$, we have that

$$
p_{\mu}^{W_1 + W_2}(t, x, y) = g(x)h(x)g(y)h(y)p_{\theta}(t, x, y)
$$
\n(3.5)

 \Box

for all $t > 0$ and $x, y \in M$.

Proof: Note that

$$
(\Delta_{\mu} + W_1 + W_2)(gh) = h\Delta_{\nu}g + W_2gh = h(\Delta_{\nu} + W_2)g = 0.
$$
\n(3.6)

Thus gh is a profile for $\Delta_{\mu} + W_1 + W_2$. The conclusion then follows from Equation [3.4.](#page-7-1) \Box

Thus an estimate on $p_{\theta}(t, x, y)$ yields an estimate on $p_{\mu}^{W_1+W_2}(t, x, y)$. In practice, we will choose W_1 so that the profile h has tractible form and such that $(M, h^2 d\mu)$ satisfies (HKE). We will then choose W_2 so that $g \approx 1$ and such that $W_1 + W_2$ is of the desired form, leading to a heat kernel estimate for $\Delta_{\mu} + W_1 + W_2$.

Lemma 3.2. Let $(M, d\mu)$ be a weighted manifold and let $W_1, W_2 \in C^{\infty}(M)$. Let $h > 0$ be smooth satsifying $(\Delta_{\mu} + W_1)h = 0$ and let $d\nu = h^2 d\mu$. Let $g > 0$ be smooth satisfying $(\Delta_{\nu} + W_2)g = 0$ and let $d\theta = g^2 d\nu$. Then the following are equivalent: (a) $\Delta_{\mu} + W_1 + W_2$ has a Green's function. (b) Δ_{ν} + W_2 has a Green's function. (c) $(M, d\theta)$ is non-parabolic.

Proof: Follows directly from integrating Lemma [3.1](#page-8-0) over $t > 0$.

Remark: In Lemma [3.2,](#page-8-1) (a) \iff (b) holds even without assuming a profile $g > 0$ for Δ_{ν} + W_2 exists. In fact, the existence of a Green's function implies the existence of a profile.

3.2 Compactly Supported Potentials

Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) for a distinguished point $o \in M$. Let $q \ge 0$ be a smooth and compactly supported function on M that is not identically zero. In this section we develop heat kernel estimates for $\Delta_{\mu} + q$. These are already known; see Grigor'yan [\[11\]](#page-28-0) in particular. They will, however, be very useful for proving our main result on quadratically decaying potentials.

Let $h > 0$ be a profile for $\Delta_{\mu} + q$. Let $d\nu = h^2 d\mu$ and consider the weighted manifold $(M, d\nu)$. To show that $(M, d\nu)$ satisfies (HKE), it suffices to prove that $(M, d\nu)$ satisfies volume doubling and the Poincaré inequality. Showing these will involve the notion of remote and anchored balls. We only need a specific version of these concepts which we define below.

Definition 3.3. Given a distinguished point $o \in M$, a ball $B(x,r)$ is **remote** if $r \leq \frac{1}{2}$ $\frac{1}{2}d(o,x)$. A ball $B(x, r)$ is **anchored** if $x = 0$.

We also introduce the volume comparison property, abbreviated (VC).

Definition 3.4. A weighted manifold $(M, d\mu)$ satisfies the **volume comparison condition** (VC) with respect to $o \in M$ if there exists a constant $C > 0$ such that for all $x \in M$ with $d(o, x) = \rho$, we have

$$
V_{\mu}(o,\rho) \le CV_{\mu}\left(x, \frac{1}{64}\rho\right). \tag{3.7}
$$

Here we cite the main theorem from Grigor'yan and Saloff-Coste [\[13\]](#page-28-13).

Theorem 3.5. (Grigor'yan, Saloff-Coste 2005) Let $(M, d\mu)$ be a complete non-compact weighted manifold satisfying (RCA) with respect to $o \in M$. Assume that $(M, d\mu)$ satisfies (VD) and (PI) for remote balls with respect to o. Then $(M, d\mu)$ satisfies (VD) and (PI) for all balls if and only if it satisfies (VC) with respect to o.

Thus to prove that $(M, d\nu)$ satisfies (VD) and (PI), it suffices to check these properties for remote balls as well as verify (VC) with respect to o.

Lemma 3.6. Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) with respect to $o \in M$. Let $q \in C_c^{\infty}(M)$ be nonnegative and not *identically zero, let* $h > 0$ *be a profile for* $\Delta_{\mu} + q$ *, and let* $d\nu = h^2 d\mu$ *. Let* $V_{\nu}(x, r) = \nu(B(x, r))$ *.* We have that

$$
V_{\nu}(x,r) \simeq V_{\mu}(x,r)(H(|x|) + H(r))^2
$$
\n(3.8)

for all $x \in M$ and all $r > 0$.

Proof: the same proof as Lemma 4.8 in Grigor'yan and Saloff-Coste [\[12\]](#page-28-12).

Theorem 3.7. Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) with respect to $o \in M$. Let $q \in C_c^{\infty}(M)$ be nonnegative and not identically zero, let $h > 0$ be a profile for $\Delta_{\mu} + q$, and let $d\nu = h^2 d\mu$. The weighted manifold $(M, d\nu)$ satisfies (VD) and (PI), and hence also (HKE).

Proof: $(M, h^2d\mu)$ satisfies (VD) and (PI) for all remote balls by Lemma 4.7 in Grigor'yan and Saloff-Coste [\[12\]](#page-28-12). Thus we must check that it satisfies (VC). Let $x \in M$ and let $\rho =$ $d(x, o)$. We have that $V_{\nu}(o, \rho) = \int_{B(o,r)} h^2 d\mu \leq h(r)^2 V(o, r) \leq h(r)^2 V(x, r) \approx V_{\nu} \left(x, \frac{1}{64} \rho\right)$.

From here we could then write down a precise estimate for the heat kernel of $\Delta_{\mu} + q$, but we do not need it right now.

Note that in the theorem above, $(M, h^2 d\mu)$ is non-parabolic. One way to see this is that, letting $d\nu = h^2 d\mu$, $(M, d\nu)$ has a non-constant bounded Δ_{ν} -superharmonic function, namely $1/h$. Therefore it has a Green's function, which we will denote $G_{\nu}(x, y)$. We now turn to estimating $G_{\nu}(x, y)$.

Lemma 3.8. There exists a constant $C > 0$ such that for all $x, y \in M$ distinct, we have

$$
G_{\nu}(x,y) \le \frac{C}{h(y)^2} \left(\int_{d(x,y)^2}^{\max(1,|y|^2)} \frac{dt}{V_{\mu}(y,\sqrt{t})} \right)_+ + \frac{C}{h(y)}.\tag{3.9}
$$

 \Box

Proof: Lemma [2.3](#page-4-0) tells us that (HKE) implies the following estimate on the Green's function:

$$
G_{\nu}(x,y) \asymp \int_{d(x,y)^2}^{\infty} \frac{dt}{V_{\nu}(y,\sqrt{t})} \asymp \int_{d(x,y)^2}^{\infty} \frac{dt}{(H(|y|) + H(\sqrt{t}))^2 V_{\mu}(y,\sqrt{t})}.
$$
(3.10)

Note that $H'(r) = \frac{re^{-1/r}}{V(r)}$ and by the chain rule, if $f(t) = H(|y|) + H(\sqrt{t})$ then $f'(t) = \frac{e^{-1/\sqrt{t}}}{2V(\sqrt{t})}$ $\frac{e^{-t/\sqrt{t}}}{2V(\sqrt{t})}$. In particular, for $t > 1$ we have $f'(t) \approx V_\mu(\sqrt{t})^{-1}$. Also, if $t \ge |y|^2$, then $V_\mu(y, \sqrt{t}) \approx V_\mu(\sqrt{t})$ by volume doubling. Thus if $d(x, y) \ge \max(1, |y|)$, we have that

$$
\int_{d(x,y)^2}^{\infty} \frac{dt}{(H(|y|) + H(\sqrt{t}))^2 V_{\mu}(y,\sqrt{t})} \approx \int_{d(x,y)^2}^{\infty} \frac{f'(t)}{f(t)^2} dt = \frac{1}{H(|y|) + H(d(x,y))}.
$$

By the same token,

$$
\int_{\max(1,|y|^2)}^{\infty} \frac{dt}{(H(|y|) + H(\sqrt{t}))^2 V_{\mu}(y,\sqrt{t})} \approx \frac{1}{H(|y|) + H(\max(1,|y|))} \approx \frac{1}{H(|y|)}.
$$

Thus we have

$$
G_{\nu}(x,y) \asymp \frac{1}{(H(|y|) + H(d(x,y)))^2} \left(\int_{d(x,y)^2}^{\max(1,|y|^2)} \frac{dt}{V_{\mu}(y,\sqrt{t})} \right)_+ + \frac{1}{H(|y|) + H(d(x,y))},
$$
(3.11)

so in particular

$$
G_{\nu}(x,y) \preceq \frac{1}{h(y)^2} \left(\int_{d(x,y)^2}^{\max(1,|y|^2)} \frac{dt}{V_{\mu}(y,\sqrt{t})} \right)_+ + \frac{1}{h(y)}.
$$

Remark: Under the same hypotheses as Lemma [3.8,](#page-9-0) one has the following two-sided on $G_{\nu}(x,y)$:

$$
G_{\nu}(x,y) \asymp \frac{1}{(H(|y|) + H(|x|))^{2}} \left(\int_{d(x,y)^{2}}^{\max(1,|y|^{2},|x|^{2})} \frac{dt}{V_{\mu}(y,\sqrt{t})} \right)_{+} + \frac{1}{H(|y|) + H(|x|)}.
$$

This is symmetric in x and y due to volume doubling.

4 Gaugeability in Non-Parabolic Manifolds

In this section we move from considering compactly supported potentials to more general ones. In the course of applying the h-transform in the previous section, we turned a parabolic weighted manifold into a non-parabolic one. Working on a non-parabolic manifold will afford us various useful notions of boundedness with respect to the Green's function. Let $(M, d\mu)$ be a complete, non-compact, non-parabolic weighted manifold. Let Δ_{μ} be the Laplacian of $(M, d\mu)$ and assume $\Delta_{\mu} \geq 0$. Let $G_{\mu}(x, y)$ be the Green's function of $(M, d\mu)$ and let $(X_t)_{t>0}$ denote Brownian motion on $(M, d\mu)$.

Remark: $(M, d\mu)$ being non-parabolic is equivalent to Brownian motion $(X_t)_{t>0}$ being transient on M.

The Markov transition kernel of Brownian motion on $(M, d\mu)$ is the heat kernel $p_{\mu}(t, x, y)$ of Δ_{μ} . We let E^x denote expectation with respect to Brownian motion started at $x \in M$. Let $W: M \to \mathbf{R}$ be smooth.

Definition 4.1. Let $(M, d\mu)$ be a complete, non-compact, non-parabolic weighted manifold with Green's function $G_{\mu}(x, y)$. $W \in C^{\infty}(M)$ is **Green-bounded on** $(M, d\mu)$ if

$$
\sup_{x\in M}\int_M G_\mu(x,y)\,|W(y)|\,d\mu(y)<+\infty.
$$

When W is Green-bounded we let $||W||_{K^{\infty}} = \sup_{x \in M} \int_M G_{\mu}(x, y) |W(y)| d\mu(y)$. We now define the Kato class at infinity.

Definition 4.2. Let $(M, d\mu)$ be a complete, non-compact, non-parabolic weighted manifold. We say that $W \in C^{\infty}(M)$ is in the **Kato infinity class** of $(M, d\mu)$, $W \in K^{\infty}(M, d\mu)$, if for some (any) exhaustion $\{\Omega_k\}_{k=0}^{\infty}$ of smooth, relatively compact domains such that $\Omega_0 \neq \emptyset$, $\overline{\Omega_k} \subseteq \Omega_{k+1}$ and $M = \bigcup_{k=0}^{\infty} \Omega_k$, letting $\Omega_k^* = M \setminus \Omega_k$ we have

$$
\lim_{k \to +\infty} \sup_{x \in M} \int_{\Omega_k^*} G_{\mu}(x, y) |W(y)| d\mu(y) = 0.
$$

It is routine to check that this definition is independent of the choice of the exhaustion $\{\Omega_k\}_{k=0}^{\infty}$, and that $W \in K^{\infty}(M, d\mu)$ implies W is Green-bounded on $(M, d\mu)$. We have the following lemma, which is easy to check.

Lemma 4.3. Let $W \in K^{\infty}(M, d\mu)$. Then the family

$$
\{ |W(y)| \, G_\mu(x, y) \colon x \in M \}
$$

is uniformly integrable on $(M, d\mu)$.

The following lemma is a setup for results in Section 5. A similar result in Euclidean space appears in Section 8 in Pinchover [\[22\]](#page-29-7).

Lemma 4.4. Let $(M, d\mu)$ be a complete, non-compact, non-parabolic weighted manifold satisfying (HKE). Let $W \in K^{\infty}(M, d\mu)$ be smooth and let $\{\Omega_k\}_{k=0}^{\infty}$ be an exhaustion of M as in Definition [4.2.](#page-11-1) For each k let $\Omega_k^* = M \setminus \Omega_k$. Then

$$
\lim_{k \to \infty} \sup_{x,y \in \Omega_k^*} \int_{\Omega_k^*} \frac{G_\mu(x,z) G_\mu(z,y) |W(z)|}{G_\mu(x,y)} d\mu(z) = 0.
$$

Proof: Let us start with a claim known as the 3G Principle.

Claim: Under the hypotheses of Lemma [4.4,](#page-11-2) there exists $C > 0$ such that for all $x, y, z \in M$ distinct,

$$
\frac{G_{\mu}(x,z)G_{\mu}(z,y)}{G_{\mu}(x,y)} \leq C(G_{\mu}(x,z) + G_{\mu}(z,y)).
$$

Proof of Claim: Let $x, y, z \in M$ be distinct. Let $d(\cdot, \cdot)$ be the geodesic distance function. By the triangle inequality, $d(x, y) \leq d(x, z) + d(z, y)$ and therefore either $d(x, y) \leq 2d(x, z)$ or $d(x, y) \le 2d(z, y)$. Assume that $d(x, y) \le 2d(x, z)$. Using Lemma [2.3,](#page-4-0) we have that

$$
G_{\mu}(x,y) \asymp \int_{d(x,y)^2}^{\infty} \frac{dt}{V_{\mu}(x,\sqrt{t})} \ge \int_{4d(x,z)^2}^{\infty} \frac{dt}{V_{\mu}(x,\sqrt{t})} \asymp G_{\mu}(x,z),
$$

the last relation obtained by the using change of variables $s = \sqrt{2}t$ and applying volume doubling. Therefore in this case we have $G_{\mu}(x, z) \preceq G_{\mu}(x, y)$ and so

$$
\frac{G_{\mu}(x,z)G_{\mu}(z,y)}{G_{\mu}(x,y)} \preceq G_{\mu}(z,y).
$$

If instead $d(x, y) \le 2d(z, y)$, the proof is the same except to first use that $G_{\mu}(x, y) = G_{\mu}(y, x)$.
This proves the claim This proves the claim.

Now assume that $W \in K^{\infty}(M, d\mu)$ and let $\{\Omega_k\}_{k=0}^{\infty}$ be an exhaustion of M as in Definition [4.2.](#page-11-1) Let $\epsilon > 0$. By definition, there exists $k_0 \in \mathbb{N}$ such that for $k \geq k_0$,

$$
\sup_{x \in \Omega_k^*} \int_{\Omega_k^*} G_{\mu}(x, y) |W(y)| d\mu(y) < \frac{\epsilon}{2C}.
$$

Here $C > 0$ is as in the claim. Let $k \geq k_0$ and let $x, y \in \Omega_k^*$. We have

$$
\int_{\Omega_k^*} \frac{G_{\mu}(x, z)G_{\mu}(z, y) \, |W(z)|}{G_{\mu}(x, y)} d\mu(z) \le C \int_{\Omega_k^*} \left(G_{\mu}(x, z) + G_{\mu}(z, y) \right) |W(z)| \, d\mu(z) < \epsilon.
$$

This proves the lemma.

Remark: Potentials W satisfying the conclusion of Lemma [4.4](#page-11-2) are known in the literature as small perturbations. The ratio of three Green's functions that appears in Lemma [4.4](#page-11-2) will be used later in Lemma [5.9.](#page-16-0) It is also related to conditional Brownian motion; see for example Zhao [\[30\]](#page-29-8) for more details.

Lemma 4.5. Let $(M, d\mu)$ be a complete, non-compact, non-parabolic weighted manifold. Let $W: M \to \mathbf{R}$ be smooth. Then W is Green-bounded on $(M, d\mu)$ if and only if

$$
\sup_{x \in M} E^x \left[\int_0^\infty |W(X_s)| \, ds \right] < +\infty.
$$

Proof: Note that by the Fubini-Tonelli theorem and the fact that $p_{\mu}(t, x, y)$ is the transition kernel for $(X_t)_{t>0}$,

$$
\int_M G_\mu(x, y) |W(y)| d\mu(y) = \int_M \left(\int_0^\infty p_\mu(t, x, y) dt \right) |W(y)| d\mu(y)
$$

$$
= \int_0^\infty \int_M p_\mu(t, x, y) |W(y)| d\mu(y) dt = \int_0^\infty E^x [|W(X_t)|] dt = E^x \left[\int_0^\infty |W(X_s)| ds \right].
$$

result follows.

The result follows.

Definition 4.6. The **Feynman-Kac gauge** of W is the function

$$
e_W(x) := E^x \left[\exp \left(- \int_0^\infty W(X_s) ds \right) \right].
$$

We say that W is **gaugeable** on $(M, d\mu)$ if $e_W < +\infty$.

Note that e_W may not be finite, and may also be zero. For more on the gauge, see the book by Chung and Zhao [\[4\]](#page-27-2) as well as the articles by Chen [\[3\]](#page-27-3) and Zhao [\[30\]](#page-29-8). We have the following well-known result, known as Khasmin'skii's Lemma.

Lemma 4.7. (Khasmin'skii's Lemma) Let W be such that $||W||_{K^{\infty}} = \alpha < 1$. Then $\sup_{x \in M} e_W(x) < (1 - \alpha)^{-1}.$

The following is a essentially a consequence of Theorem 2 in Zhao [\[30\]](#page-29-8) in Euclidean space; we reproduce the proof on a weighted manifold.

Theorem 4.8. Let $(M, d\mu)$ be a complete, non-compact, non-parabolic weighted manifold. Let $W \in K^{\infty}(M, d\mu)$. Then W is gaugeable on $(M, d\mu)$ if and only if there exists a smooth function $h > 0$ satisfying $(\Delta_{\mu} + W)h = 0$ and $h \approx 1$.

Proof: (\Rightarrow) Set $h(x) = e_W(x)$. By hypothesis, h is bounded above. Let $C > 0$ such that $\sup_{x\in M}\int_M G_\mu(x,y)\,|W(y)|\,d\mu(y)\leq C.$ To see that h is bounded below, note that by Jensen's inequality,

$$
h(x) = E^x \left[\exp \left(- \int_0^\infty W(X_s) ds \right) \right] \ge \exp \left(- E^x \left[\int_0^\infty W(X_s) ds \right] \right) \ge e^{-C},
$$

the last by Lemma [4.5.](#page-12-0) Thus $h \approx 1$.

Now we show that $(\Delta_{\mu} + W)h = 0$. By the Fubini-Tonelli theorem as well as the Markov property and integrating by parts, we have

$$
\int_M G_\mu(x, y) W(y) h(y) d\mu(y) = E^x \left[\int_0^\infty W(X_t) E^{X_t} \left[\exp \left(- \int_0^\infty W(X_s) ds \right) \right] \right]
$$

=
$$
E^x \left[\int_0^\infty W(X_t) \exp \left(- \int_t^\infty W(X_s) ds \right) \right] = E^x \left[1 - \exp \left(- \int_0^\infty W(X_s) ds \right) \right]
$$

=
$$
1 - h(x).
$$

Applying the distributional version of Δ_{μ} to both sides of

$$
\int_{M} G_{\mu}(x, y) W(y) h(y) d\mu(y) = 1 - h(y)
$$
\n(4.1)

yields that $(\Delta_{\mu} + W)h = 0$ as a distribution. h is continuous using the result of Lemma [4.3](#page-11-3) that $\{G_{\mu}(x,y)W(y)h(y): x \in M\}$ is uniformly integrable. By elliptic regularity, h is smooth.

(←) Let $h > 0$ be smooth such that $(\Delta_{\mu} + W)h = 0$ and $h \approx 1$. Let $\{\Omega_k\}_{k=0}^{\infty}$ be an exhaustion as in Definition [4.2.](#page-11-1) Fix $x \in M$ and let $k_0 \in \mathbb{N}$ be such that $x \in \Omega_{k_0}$. By the Feynman-Kac formula, for all $k \geq k_0$ we have

$$
h(x) = E^x \left[\exp \left(- \int_0^{\tau_k} W(X_s) ds \right) h(X_{\tau_k}) \right] \asymp E^x \left[\exp \left(- \int_0^{\tau_k} W(X_s) ds \right) \right].
$$

Here $\tau_k = \inf \{ t : X_t \notin \Omega_k \}$ is the first exit time of Brownian motion from Ω_k . By Fatou's Lemma, we have

$$
E^x \left[\exp \left(- \int_0^\infty W(X_s) ds \right) \right] \le \liminf_{k \to \infty} E^x \left[\exp \left(- \int_0^{\tau_k} W(X_s) ds \right) \right] \preceq h(x) \preceq 1.
$$

 \Box

Thus W is gaugeable.

Remark: See Murata [\[18\]](#page-28-14) for a version of Equation [4.1](#page-13-0) for more general elliptic operators.

We finish this section with the following lemma.

Lemma 4.9. Let $W \in K^{\infty}(M, d\mu)$ such that

$$
\sup_{x\in M}\int_M G_\mu(x,y)W_-(y)d\mu(y)<1.
$$

Then $\Delta_{\mu} + W$ is gaugeable on $(M, d\mu)$.

Proof: By the hypothesis and Khasmin'skii's Lemma, $\Delta_{\mu} - W_{-}$ is gaugeable on $(M, d\mu)$.
By monotonicity of the Feynman-Kac gauge, $\Delta_{\mu} + W$ is gaugeable on $(M, d\mu)$. By monotonicity of the Feynman-Kac gauge, $\Delta_{\mu} + W$ is gaugeable on $(M, d\mu)$.

5 Subcriticality and Criticality Theory

Definition 5.1. Let $(M, d\mu)$ be a complete, non-compact weighted manifold and let $W \in$ $C^{\infty}(M)$. We say that:

(i) $\Delta_{\mu} + W$ is **subcritical** on $(M, d\mu)$ if $\Delta_{\mu} + W \geq 0$ and $\Delta_{\mu} + W$ admits a positive Green's function.

(ii) $\Delta_{\mu} + W$ is **critical** on $(M, d\mu)$ if $\Delta_{\mu} + W \geq 0$ and $\Delta_{\mu} + W$ is not subcritical. (iii) $\Delta_{\mu} + W$ is **supercritical** on $(M, d\mu)$ if $\Delta_{\mu} + W \not\geq 0$.

By the Allegretto-Piepenbrink Theorem, $\Delta_{\mu} + W \geq 0$ if and only if $\Delta_{\mu} + W$ has a profile $h > 0$ on M satisfying $(\Delta_{\mu} + W)h = 0$. Letting $d\nu = h^2 d\mu$, we see that the Green's function $G_{\mu}^{W}(x, y)$ of $\Delta_{\mu} + W$, if it exists, satisfies $G_{\mu}^{W}(x, y) = h(x)h(y)G_{\nu}(x, y)$, where $G_{\nu}(x, y)$ is the Green's function of Δ_{ν} on $(M, d\nu)$.

Lemma 5.2. Let $(M, d\mu)$ be a complete, non-compact weighted manifold. Let $q \in C^{\infty}(M)$ be such that there exists a profile $h > 0$ satisfying $(\Delta_{\mu} + q)h = 0$ and let $d\nu = h^2 d\mu$. Let $W \in C^{\infty}(M)$. Then $\Delta_{\mu} + W$ is subcritical on $(M, d\mu)$ if and only if $\Delta_{\nu} + W - q$ is subcritical on $(M, d\nu)$. The previous sentence also holds with "critical" or "supercritical" replacing "subcritical."

Proof: By Lemma [3.2](#page-8-1) and the subsequent remark, it suffices to prove that $\Delta_{\mu} + W \ge 0$ if and only if $\Delta_{\nu} + W - q \ge 0$. This is a routine exercise. and only if $\Delta_{\nu} + W - q \geq 0$. This is a routine exercise.

Lemma 5.3. Let $(M, d\mu)$ be a complete, non-compact, non-parabolic weighted manifold. Let $q \in C_c^{\infty}(M)$. Then q is Green-bounded on $(M, d\mu)$.

Proof: Follows from Lemma 10.3 (a) in Grigor'yan [\[11\]](#page-28-0).

Lemma 5.4. Let $(M, d\mu)$ be a complete, non-compact, non-parabolic weighted manifold. Let $q \in C_c^{\infty}(M)$. Then there exists $c > 0$ such that $\Delta_{\mu} + cq \geq 0$.

Proof: Since q is Green-bounded on $(M, d\mu)$ by the previous lemma, there exists $c > 0$ such that

$$
\sup_{x\in M}\int_M G(x,y)\,|cq(y)|\,d\mu(y)<1.
$$

By Theorem [4.8,](#page-13-1) $\Delta_{\mu} + cq$ has a profile $h > 0$ with $(\Delta_{\mu} + cq)h = 0$ and $h \approx 1$. By the Allegretto-Piepenbrink Theorem, $\Delta_{\mu} + cq > 0$. Allegretto-Piepenbrink Theorem, $\Delta_{\mu} + cq \geq 0$.

The next lemma, which goes back to Murata and Pinchover, connects subcriticality to compactly supported perturbations. See Devyver [\[7\]](#page-28-1), Theorem 3.7 for a similar result with different proof.

Lemma 5.5. Let $(M, d\mu)$ be a complete, non-compact weighted manifold. Let $W \in C^{\infty}(M)$ be bounded. Then $\Delta_{\mu} + W$ is subcritical if and only if there exists $q \in C_c^{\infty}(M)$ non-negative and not identically zero such that $\Delta_{\mu} + W - q \geq 0$.

Proof: (\Rightarrow) Assume $\Delta_{\mu} + W$ is subcritical. Let $h > 0$ be a profile for $\Delta_{\mu} + W$. Let $d\nu = h^2 d\mu$ and consider the weighted manifold $(M, d\nu)$. By Lemma [3.2,](#page-8-1) Δ_{ν} is subcritical, i.e. $(M, d\nu)$ is non-parabolic. Let $\varphi \in C_c^{\infty}(M)$ be non-positive and not identically zero. By Lemma [5.4,](#page-15-0) there exists $c > 0$ such that $\Delta_{\nu} + c\varphi \geq 0$. Set $q = -c\varphi$. Then since $\Delta_{\nu} - q \geq 0$ we have $\Delta_{\mu} + W - q \geq 0$ as desired.

(←) Let $q \in C_c^{\infty}(M)$ be non-negative and not identically zero such that $\Delta_{\mu} + W - q \ge 0$. By the Allegretto-Piepenbrink Theorem, there exists a profile $h > 0$ for $\Delta_{\mu} + W - q$. Let $d\nu = h^2 d\mu$. Since $\Delta_{\nu} \geq 0$, we clearly have $\Delta_{\nu} + q \geq 0$. Thus by the Allegretto-Piepenbrink Theorem, there exists a profile $g > 0$ for $\Delta_{\nu} + q$. Let $d\theta = g^2 d\nu$.

Now we have

$$
\Delta_{\theta}\left(\frac{1}{g}\right) = \frac{1}{g}\Delta_{\nu}(1) + \frac{q}{g} = \frac{q}{g} \ge 0.
$$

Thus $1/g$ is Δ_{θ} -superharmonic. Since $1/g$ is positive and non-constant, by Liouville's The-orem [1.10,](#page-3-2) $(M, d\theta)$ is non-parabolic. Therefore Δ_{θ} is subcritical. Unraveling we find via

□

Lemma [3.2](#page-8-1) that $\Delta_{\nu} + q$ is subcritical and so is $\Delta_{\mu} + (W - q) + q = \Delta_{\mu} + W$.

 \Box

We now have the following result from Devyver [\[7\]](#page-28-1).

Theorem 5.6. (Devyver [\[7\]](#page-28-1), Theorem 3.2) Let $(M, d\mu)$ be a complete, non-compact, nonparabolic weighted manifold. Let $W \in C^{\infty}(M)$ be Green-bounded such that $W_{-} \in K^{\infty}(M, d\mu)$ and such that $\Delta_{\mu}+W$ is subcritical. Then there exists a profile $h > 0$ satisfying $(\Delta_{\mu}+W)h =$ 0 as well as $h \approx 1$.

So subcritical operators have profiles that are approximately constant. We have the following result that ties together several concepts discussed so far. This is generally known; see Devyver [\[7\]](#page-28-1) Theorem 3.2 and Theorem 3.7 as well as Zhao [\[30\]](#page-29-8) Theorem 2, but we find it helpful to collect them in one place.

Theorem 5.7. Let $(M, d\mu)$ be a complete, non-compact, non-parabolic weighted manifold satisfying (HKE). Let $W \in K^{\infty}(M, d\mu)$. The following are equivalent:

(a) Δ_{μ} + W is subcritical.

(b) W is gaugeable on $(M, d\mu)$.

(c) There exists a profile $h > 0$ for $\Delta_{\mu} + W$ satisfying $h \approx 1$.

(d) There exists $q \in C_c^{\infty}(M)$ non-negative and not identically zero such that $\Delta_{\mu} + W - q \ge 0$.

Proof: (b) \iff (c), (a) \Rightarrow (c), and (a) \iff (d) were already shown in Theorem [4.8,](#page-13-1) Theorem [5.6,](#page-16-1) and Lemma [5.5](#page-15-1) respectively. Thus it suffices to show that $(c) \Rightarrow (a)$.

(c) \Rightarrow (a): Let $h > 0$ be a profile for $\Delta_{\mu} + W$ satisfying $h \approx 1$ and let $d\nu = h^2 d\mu$. Notably, since the property (HKE) is equivalent to the properties (VD) and (PI) , it is routine to check that (VD) and (PI) for $(M, d\mu)$ imply the same for $(M, d\nu)$ and so $(M, d\nu)$ satisfies (HKE). Furthermore, $(M, d\nu)$ is non-parabolic as well and so has a Green's function $G_{\nu}(x, y)$. We then see that a Green's function for $\Delta_{\mu}+W$ exists with $G_{\mu}^{W}(x, y) = h(x)h(y)G_{\nu}(x, y)$.

The following well-known proposition produces many examples of subcritical Schrödinger operators.

Proposition 5.8. Let $(M, d\mu)$ be a complete, non-compact, weighted manifold. Let $W \in$ $C^{\infty}(M)$ be bounded, nonnegative and not identically zero. Then $\Delta_{\mu} + W$ is subcritical on $(M, d\mu).$

Proof: By hypothesis there exists $q \in C_c^{\infty}(M)$ with $0 \le q \le W$. Thus $W - q \ge 0$ and so $\Delta_{\mu} + W - q \geq 0$. By Lemma [5.5,](#page-15-1) $\Delta_{\mu} + W$ is subcritical.

All this is in contrast to the critical case, which we now cite from Pinchover [\[20\]](#page-28-15).

Lemma 5.9. (Pinchover [\[20\]](#page-28-15), Lemma 2.5) Let $(M, d\mu)$ be a complete, non-compact, nonparabolic weighted manifold. Let $\{\Omega_k\}_{k=0}^{\infty}$ be an exhaustion of M as in Definition [4.2,](#page-11-1) and let $\Omega_k^* = M \setminus \Omega_k$. Let $W \in C^{\infty}(M)$ and assume that $\Delta_{\mu} + W$ is critical and that

$$
\lim_{k \to \infty} \sup_{x,y \in \Omega_k^*} \int_{\Omega_k^*} \frac{G_\mu(x,z) G_\mu(z,y) |W(z)|}{G_\mu(x,y)} d\mu(z) = 0.
$$

Let $o \in M$ be a distinguished point and let $h > 0$ be a profile for $\Delta_{\mu} + W$. Outside a compact set containing o we have

$$
h(x) \asymp G_{\mu}(x, o).
$$

With further estimates on the Green's function, we can estimate the profile of critical Schrödinger operator.

Lemma 5.10. Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) with respect to a distinguished point $o \in M$. Let $q \in C_c^{\infty}(M)$ be nonnegative and not identically zero, let $h > 0$ be a profile for $\Delta_{\mu} + q$, and let $d\nu = h^2 d\mu$. Let $W \in K^{\infty}(M, d\nu)$ be such that $\Delta_{\nu} + W$ is critical, and let $g > 0$ be a profile for $\Delta_{\nu} + W$. Then

$$
g \asymp \frac{1}{h}.
$$

Proof: Because $(M, d\nu)$ is non-parabolic and satisfies (HKE), Lemma [4.4](#page-11-2) implies that the hypotheses of Lemma [5.9](#page-16-0) are satisfied. Therefore by Lemma [5.9](#page-16-0)

$$
g(x) \asymp G_{\nu}(x, o)
$$

outside a compact set. However, by Expression [3.11](#page-10-0) in the proof of Lemma [3.8](#page-9-0) we have, for $|x| \geq 1$,

$$
G_{\nu}(x, o) = G_{\nu}(o, x) \asymp \frac{1}{(H(|x|) + H(|x|))^{2}} \left(\int_{|x|^{2}}^{\max(1, |x|^{2})} \frac{dt}{V_{\mu}(x, \sqrt{t})} \right)_{+} + \frac{1}{H(|x|) + H(|x|)}
$$

$$
\asymp \frac{1}{H(|x|)} \asymp \frac{1}{h(x)}.
$$

Th

$$
g\asymp \frac{1}{h}
$$

outside of a compact set, which can be extended to all of M by noting that each function is approximately a constant on any fixed compact set. □

Remark: The results in this section when $M = \mathbb{R}^2$ should be compared to those of Murata in $[15]$ and $[17]$, where similar results were obtained for W satisfying a form of polynomial decay.

6 Potentials with Faster Than Quadratic Decay: Main Results

We now turn to determining which potentials are Green-bounded and Kato infinity class.

Lemma 6.1. Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) with respect to $o \in M$. Let

$$
H(|y|) = 1 + \left(\int_1^{|y|^2} \frac{dt}{V_\mu(\sqrt{t})}\right)_+
$$

and let

$$
\widehat{H}(y) = 1 + \left(\int_1^{|y|^2} \frac{dt}{V_\mu(y, \sqrt{t})} \right)_+.
$$

Let $q \in C_c^{\infty}(M)$ be nonnegative and not identically zero, let $h > 0$ be a profile for $\Delta_{\mu} + q$, and let $d\nu = h^2 d\mu$. Let $W \in C^{\infty}(M)$ be bounded such that

$$
\int_M |W(y)| (H(|y|) + \widehat{H}(y))d\mu(y) < +\infty.
$$

Then W is Green-bounded on $(M, d\nu)$.

Proof: Let W be as in the hypothesis, let $C = \sup_M |W|$ and let $I = \int_M |W(y)| h(y) d\mu(y)$. We have that

$$
\int_M G_{\nu}(x, y) |W(y)| d\nu(y) = \int_M G_{\nu}(x, y) |W(y)| h(y)^2 d\mu(y)
$$

$$
\leq \int_M |W(y)| \left(\int_{d(x, y)^2}^{\max(1, |y|^2)} \frac{dt}{V_{\mu}(y, \sqrt{t})} \right)_+ d\mu(y) + \int_M |W(y)| h(y) d\mu(y).
$$

Let us estimate $\int_M |W(y)| \left(\int_{d(x,y)^2}^{\max(1,|y|^2)} \right)$ $\frac{d}{dx} \frac{d(x,y)^2}{dx} \frac{dt}{V_\mu(y,\sqrt{t})}$ $\overline{ }$ $+\frac{d\mu(y)}{dy}$ by breaking the domain of integration into pieces, namely $M = B(x, 1) \cup (M \setminus B(x, 1)).$

We have that

$$
\int_{B(x,1)} |W(y)| \left(\int_{d(x,y)^2}^{\max(1,|y|^2)} \frac{dt}{V_{\mu}(y,\sqrt{t})} \right)_+ d\mu(y)
$$
\n
$$
\leq \int_{B(x,1)} |W(y)| \left(\int_{d(x,y)^2}^1 \frac{dt}{V_{\mu}(y,\sqrt{t})} \right)_+ d\mu(y) + \int_{B(x,1) \setminus B(o,1)} |W(y)| \left(\int_1^{|y|^2} \frac{dt}{V_{\mu}(y,\sqrt{t})} \right) d\mu(y)
$$
\n
$$
\leq \left(\sup_{B(x,1)} |W| \right) \int_{B(x,1)} \left(\int_{d(x,y)^2}^1 \frac{dt}{V_{\mu}(y,\sqrt{t})} \right)_+ d\mu(y) + \int_{B(x,1)} |W(y)| \widehat{H}(y) d\mu(y).
$$

Note that if $y \in B(x,\sqrt{t})$, then $B(x,\sqrt{t}) \subseteq B(y,2\sqrt{t})$. Thus by volume doubling, $V_{\mu}(x, \sqrt{t}) \leq C_{VD} V_{\mu}(y, \sqrt{t})$. By the Fubini-Tonelli theorem, we have

$$
\int_{B(x,1)} \left(\int_{d(x,y)^2}^1 \frac{dt}{V_\mu(y,\sqrt{t})} \right)_+ d\mu(y) = \int_0^1 \int_{B(x,\sqrt{t})} \frac{1}{V_\mu(y,\sqrt{t})} d\mu(y) dt
$$
\n
$$
\leq \int_0^1 \int_{B(x,\sqrt{t})} \frac{C_{VD}}{V_\mu(x,\sqrt{t})} d\mu(y) dt \leq C_{VD}.
$$

The next piece is integrating over $M \setminus B(x, 1)$. We have that

$$
\int_{M\setminus B(x,1)} |W(y)| \left(\int_{d(x,y)^2}^{\max(1,|y|^2)} \frac{dt}{V_{\mu}(y,\sqrt{t})} \right)_+ d\mu(y)
$$

$$
\leq \int_{M\setminus B(x,1)} |W(y)| \left(\int_1^{|y|^2} \frac{dt}{V_{\mu}(y,\sqrt{t})} \right)_+ d\mu(y) \leq \int_{M\setminus B(x,1)} |W(y)| \widehat{H}(y) d\mu(y).
$$

Putting it all together we have that

$$
\int_{M} |W(y)| \left(\int_{d(x,y)^2}^{\max(1,|y|^2)} \frac{dt}{V_{\mu}(\sqrt{t})} \right)_{+} d\mu(y)
$$
\n
$$
= \int_{B(x,1)} |W(y)| \left(\int_{d(x,y)^2}^{\max(1,|y|^2)} \frac{dt}{V_{\mu}(\sqrt{t})} \right)_{+} d\mu(y) + \int_{M \setminus B(x,1)} |W(y)| \left(\int_{d(x,y)^2}^{\max(1,|y|^2)} \frac{dt}{V_{\mu}(\sqrt{t})} \right)_{+} d\mu(y)
$$
\n
$$
\leq C_{VD} \sup_{B(x,1)} |W| + \int_{M} |W(y)| \widehat{H}(y) d\mu(y).
$$

Thus we have that

$$
\int_{M} G_{\nu}(x, y) |W(y)| d\nu(y)
$$

\n
$$
\leq \int_{M} |W(y)| \left(\int_{d(x, y)^{2}}^{\max(1, |y|^{2})} \frac{dt}{V_{\mu}(\sqrt{t})} \right)_{+} d\mu(y) + \int_{M} |W(y)| h(y) d\mu(y)
$$

\n
$$
\leq C_{VD} \sup_{B(x, 1)} |W| + \int_{M} |W(y)| (H(|y|) + \widehat{H}(y)) d\mu(y) < +\infty.
$$

Since this bound is uniform in $x \in M$, we are done.

Lemma 6.2. Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) with respect to $o \in M$. Let $q \in C_c^{\infty}(M)$ be nonnegative and not *identically zero, let* $h > 0$ *be a profile for* $\Delta_{\mu} + q$ *, and let* $d\nu = h^2 d\mu$ *. Let* $W \in C_0^{\infty}(M)$ such that Z

$$
\int_M |W(y)| (H(|y|) + \widehat{H}(y))d\mu(y) < +\infty.
$$

Then $W \in K^{\infty}(M, d\nu)$.

Proof: The same proof as that of Lemma [6.1](#page-17-0) above, except using that if $\{\Omega_k\}_{k=0}^{\infty}$ is an exhaustion of M as in Definition [4.2,](#page-11-1) then

$$
\lim_{k \to \infty} \sup_{\Omega_k^*} |W| = \lim_{k \to \infty} \int_{\Omega_k^*} |W(y)| (H(|y|) + \widehat{H}(y)) d\mu(y) = 0.
$$

 \Box

 \Box

Proposition 6.3. Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) with respect to $o \in M$. Assume further there exists $C > 0$ with

$$
H(y) \leq CH(|y|)
$$

for all $y \in M$, and that there exist $\delta > 0$ and $C_{\delta} > 0$ such that for all $1 \leq s < r$ we have

$$
\frac{V_{\mu}(r)}{V_{\mu}(s)} \le C_{\delta} \left(\frac{r}{s}\right)^{2+\delta}.
$$
\n(6.1)

Let $W \in C^{\infty}(M)$ be such that for constants $c, \epsilon > 0$ and all $x \in M$ we have

$$
|W(x)| \le \langle x \rangle^{-(2+\delta+\epsilon)}.
$$
\n(6.2)

Let $q \geq 0$ be smooth, compactly supported and not identically zero, let $h > 0$ be a profile for $\Delta_{\mu} + q$, and let $d\nu = h^2 d\mu$. Then $W \in K^{\infty}(M, d\nu)$.

Proof: By Lemma [6.2,](#page-19-0) it suffices to prove that $\int_M |W(y)| (H(|y|) + \hat{H}(y))d\mu(y) < +\infty$. We now have

$$
\int_{M} |W(y)| (H(|y|) + \hat{H}(y)) d\mu(y) \leq \int_{M} |W(y)| H(|y|) d\mu(y)
$$

\n
$$
\leq \int_{B(o,1)} |W(y)| H(|y|) d\mu(y) + \sum_{n=0}^{\infty} \int_{B(o,2^{n+1}) \setminus B(o,2^{n})} (2^{n})^{-(2+\delta+\epsilon)} \left(\int_{1}^{2^{n}} \frac{s}{V_{\mu}(s)} ds \right) d\mu
$$

\n
$$
\leq 1 + \sum_{n=0}^{\infty} (2^{n})^{-(2+\delta+\epsilon)} \left(\int_{1}^{2^{n}} \frac{s}{V_{\mu}(s)} ds \right) V_{\mu}(2^{n}) = 1 + \sum_{n=0}^{\infty} \left(\int_{1}^{2^{n}} \frac{V_{\mu}(2^{n})}{V_{\mu}(s)} s ds \right) (2^{n})^{-(2+\delta+\epsilon)}
$$

\n
$$
\leq 1 + \sum_{n=0}^{\infty} \left(\int_{1}^{2^{n}} C_{\delta} \left(\frac{2^{n}}{s} \right)^{2+\delta} s ds \right) (2^{n})^{-(2+\delta+\epsilon)} = 1 + C_{\delta} \sum_{n=0}^{\infty} \left(\int_{1}^{2^{n}} s^{-(1+\delta)} ds \right) (2^{n})^{-\epsilon}
$$

\n
$$
\leq 1 + C_{\delta} \left(\frac{1}{\delta} \right) \sum_{n=0}^{\infty} (2^{-\epsilon})^{n} = 1 + C_{\delta} \left(\frac{1}{\delta} \right) \frac{1}{1 - 2^{-\epsilon}} < +\infty.
$$

Remark: The condition $\widehat{H}(y) \leq CH(|y|)$ follows if we know that $V_{\mu}(r) \preceq V_{\mu}(y, r)$ over all $y \in M$, $0 < r < |y|$. We will see later in [7.5](#page-24-0) an example that satisfies the first of these properties but not the second.

This brings us to our main theorem. Let us recall once again that $H(r) = 1 + \left(\int_1^{r^2}$ 1 dt $\frac{dv}{V_\mu(\sqrt{t})}$ $\overline{ }$ + and $\widehat{H}(y) = 1 + \left(\int_{1}^{|y|^2}$ 1 $\frac{dt}{V_\mu(y,\sqrt{t})}$ \setminus + .

Theorem 6.4. Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) with respect to $o \in M$. Let $W \in C_0^{\infty}(M)$ be such that

$$
\int_M |W(y)| (H(|y|) + \widehat{H}(y))d\mu(y) < +\infty.
$$

Let $p_{\mu}^{W}(t,x,y)$ denote the heat kernel of $\Delta_{\mu}+W$. There exist constants $c_1, c_2, c_3, c_4 > 0$ such that:

(i) If $\Delta_{\mu} + W$ is subcritical on $(M, d\mu)$, then for all $t > 0$ and all $x, y \in M$ we have

$$
\frac{c_1H(|x|)H(|y|)}{(H(|y|) + H(\sqrt{t}))^2 V_\mu(y, \sqrt{t})}e^{-c_2\frac{d(x,y)^2}{t}} \le p_\mu^W(t,x,y) \le \frac{c_3H(|x|)H(|y|)}{(H(|y|) + H(\sqrt{t}))^2 V_\mu(y, \sqrt{t})}e^{-c_4\frac{d(x,y)^2}{t}}.
$$

(ii) If $\Delta_{\mu} + W$ is critical on $(M, d\mu)$, then for all $t > 0$ and $x, y \in M$ we have

$$
\frac{c_1}{V_\mu(y,\sqrt{t})}e^{-c_2\frac{d(x,y)^2}{t}} \le p_\mu^W(t,x,y) \le \frac{c_3}{V_\mu(y,\sqrt{t})}e^{-c_4\frac{d(x,y)^2}{t}}.
$$

Proof: Let $q \in C_c^{\infty}(M)$ be nonnegative and not identically zero. Let $h > 0$ be such that $(\Delta_{\mu} + q)h = 0$ and let $d\nu = h^2 d\mu$. By Lemma [6.2](#page-19-0) we have that $W - q \in K^{\infty}(M, d\nu)$.

(i) Since $\Delta_{\mu} + W$ is subcritical on $(M, d\mu)$, $\Delta_{\nu} + W - q$ is subcritical on $(M, d\nu)$. Hence by Theorem [5.6,](#page-16-1) there exists a profile $g > 0$ for $\Delta_{\nu} + W - q$ with $g \approx 1$. Thus if we let $d\theta = g^2 d\nu$, the weighted manifold $(M, d\theta)$ satisfies (VD) and (PI) since $(M, d\nu)$ does. Therefore $(M, d\theta)$ satisfies (HKE). The result then follows from Lemma [3.1](#page-8-0) as well as using Lemma [3.6](#page-9-1) to get $V_{\theta}(x,\sqrt{t}) \asymp (H(|y|) + H(\sqrt{t}))^2 V_{\mu}(x,\sqrt{t}).$ \Box

(ii) Next, instead assume that $\Delta_{\mu} + W$ is critical on $(M, d\mu)$. By Lemma [5.2,](#page-15-2) $\Delta_{\nu} + W - q$ is critical on $(M, d\nu)$. Let $g > 0$ be a profile for $\Delta_{\nu} + W - q$. By Lemma [5.10](#page-17-1) we have that $g \approx 1/h$. Therefore $gh \approx 1$ and so $(M, d\theta)$ as in the proof of *(i)* satisfies (HKE) because $(M, d\mu)$ does. Furthermore, we have $V_{\theta}(x, \sqrt{t}) \approx V_{\mu}(x, \sqrt{t})$. The result follows. $(M, d\mu)$ does. Furthermore, we have $V_{\theta}(x, \sqrt{t}) \approx V_{\mu}(x, \sqrt{t})$. The result follows.

Remark: This result should be compared with Theorem 10.10 of Grigor'yan [\[11\]](#page-28-0) as well as our combined statement of Murata and Grigor'yan in Theorem [1.2.](#page-2-0) In fact, using our estimates on the profiles, Theorem [6.4](#page-20-0) can be proved using Grigor'yan's result, which is stated when $W = \frac{\Delta_{\mu}\varphi}{\varphi}$ $\frac{\mu \varphi}{\varphi}$, with assumptions on the behavior of $\varphi > 0$. What we have supplied is an estimate of the profile $h > 0$ for $\Delta_{\mu} + W$ when W satisfies the hypothesis of Theorem [6.4;](#page-20-0) in part (i), we have $h(x) \approx H(|x|)$, and in part (ii), we have $h(x) \approx 1$. In this sense we can view our result as building on that of Murata in [\[15\]](#page-28-6) stated in Theorem [1.1.](#page-1-0)

7 Applications and Examples

By Proposition [5.8,](#page-16-2) positive smooth potentials W yield subcritical operators $\Delta_{\mu} + W$. Let us now address a wide class of W to which our Main Theorem [6.4](#page-20-0) applies: W that decay to zero at infinity faster than quadratically.

Theorem 7.1. Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) with respect to $o \in M$. Assume that there exists $C > 0$ such that

$$
\widehat{H}(y) \leq CH(|y|)
$$

for all $y \in M$ and that there exist $\delta > 0$ and $C_{\delta} > 0$ such that for all $1 \leq s < r$ we have

$$
\frac{V_{\mu}(r)}{V_{\mu}(s)} \leq C_{\delta} \left(\frac{r}{s}\right)^{2+\delta}.
$$

Let $W \in C^{\infty}(M)$ be not identically zero for which there exist $c, \epsilon > 0$ such that for all $x \in M$,

$$
0 \le W(x) \le c \langle x \rangle^{-(2+\delta+\epsilon)}.
$$

Letting $p_{\mu}^{W}(t,x,y)$ denote the heat kernel of $\Delta_{\mu} + W$, there exist constants c_1, c_2, c_3, c_4 such that for all $t > 0$ and $x, y \in M$ we have

$$
\frac{c_1H(|x|)H(|y|)}{(H(|y|) + H(\sqrt{t}))^2 V_\mu(y, \sqrt{t})}e^{-c_2\frac{d(x,y)^2}{t}} \le p_\mu^W(t,x,y) \le \frac{c_3H(|x|)H(|y|)}{(H(|y|) + H(\sqrt{t}))^2 V_\mu(y, \sqrt{t})}e^{-c_4\frac{d(x,y)^2}{t}}.
$$

Proof: Since $W \geq 0$ is not identically zero, $\Delta_{\mu} + W$ is subcritical by Proposition [5.8.](#page-16-2) By Proposition [6.3,](#page-20-1) W satisfies the hypotheses of the Main Theorem [6.4\(](#page-20-0)i), and the conclusion follows. □

Consider the case when $(M, d\mu) = (\mathbf{R}^2, dx)$, where \mathbf{R}^2 has the Euclidean metric and dx denotes Lebesgue measure. Potentials that decay faster than quadratically as in Theorem [7.1](#page-21-0) are already covered by the results of Murata and Grigor'yan mentioned in the introduction as Theorem [1.2.](#page-2-0) We note, however, that the Main Theorem [6.4](#page-20-0) still offers the following addition.

Corollary 7.2. Let $W \in C_0^{\infty}(\mathbb{R}^2)$ be such that $\log \langle x \rangle |W(x)| \in L^1(\mathbb{R}^2, dx)$. Let $p^W(t, x, y)$ denote the heat kernel of $\Delta + W$. There exist constants $c_1, c_2, c_3, c_4 > 0$ such that: (i) If $\Delta + W$ is subcritical, then for all $t > 0$, $x, y \in \mathbb{R}^2$,

$$
\frac{c_1 \log \langle x \rangle \log \langle y \rangle}{t \log(\langle x \rangle + \sqrt{t}) \log(\langle y \rangle + \sqrt{t})} e^{-c_2 \frac{|x-y|^2}{t}} \le p^W(t, x, y) \le \frac{c_3 \log \langle x \rangle \log \langle y \rangle}{t \log(\langle x \rangle + \sqrt{t}) \log(\langle y \rangle + \sqrt{t})} e^{-c_4 \frac{|x-y|^2}{t}}.
$$

(ii) If $\Delta + W$ is critical, then for all $t > 0$, $x, y \in \mathbb{R}^2$,

$$
\frac{c_1}{t}e^{-c_2\frac{|x-y|^2}{t}} \le p^W(t,x,y) \le \frac{c_3}{t}e^{-c_4\frac{|x-y|^2}{t}}.
$$

Proof: It is routine to check that (\mathbb{R}^2, dx) is complete, non-compact, parabolic, satisfies (HKE) as well as (RCA) with respect to the origin. If $W \in C_0^{\infty}(\mathbb{R}^2)$ is such that $\log \langle x \rangle |W(x)| \in L^1(\mathbf{R}^2, dx)$, then by noting that $H(|y|) \approx \hat{H}(y) \approx \log \langle y \rangle$ we can apply Theorem [6.4](#page-20-0) as well as symmetrization.

Remark: Subcritical operators are plentiful, as any non-negative, not identically zero potential satisfying the hypothesis will yield a subcritical operator. On the other hand, critical operators other than Δ_{μ} are difficult to describe, but we show that many exist in Proposition [7.3.](#page-23-0)

7.1 Existence of Critical Operators

The suspicious reader of Theorem [6.4\(](#page-20-0)ii) may wonder whether, on a parabolic manifold, there exist critical Schrödinger operators $\Delta_{\mu} + W$ other than $W = 0$. It is difficult to write down examples explicitly, but we can show that many exist. See Pinchover [\[21\]](#page-29-9) Theorem 4.1 for a related result.

Proposition 7.3. Let $(M, d\mu)$ be a complete, non-compact, parabolic weighted manifold satisfying (HKE) as well as (RCA) with respect to $o \in M$. Let $q \in C_c^{\infty}(M)$ be nonnegative and not identically zero, let $h > 0$ be a profile for $\Delta_{\mu} + q$, and let $d\nu = h^2 d\mu$. Let $W_1, W_2 \in$ $C^{\infty}(M)$ be bounded such that:

(i) $\Delta_{\mu} + W_1$ is subcritical on $(M, d\mu)$, (ii) $W_1, W_2 \in K^{\infty}(M, d\nu)$, and (iii) $W_2(x) > q(x)$ for some point $x \in M$. Then there exists $c > 0$ such that $\Delta_{\mu} + W_1 - c(W_2 - q)$ is critical on $(M, d\mu)$.

Proof: By Lemma [5.2,](#page-15-2) $\Delta_{\nu} + W_1 - q$ is subcritical on $(M, d\nu)$. Note that $W_1 - q$, $W_2 - q \in$ $K^{\infty}(M, d\nu)$ as well. Since $(M, d\nu)$ satisfies (HKE), by Theorem [5.7,](#page-16-3) there exists a profile $g > 0$ for $\Delta_{\nu} + W_1 - q$ such that $g \approx 1$.

Let $d\theta = g^2 d\nu$. Since $(M, d\nu)$ satisfies (HKE), so does $(M, d\theta)$. In fact, by Lemma [2.3](#page-4-0) and the fact that $V_{\nu}(x, r) \simeq V_{\theta}(x, r)$ over $x \in M$ and $r > 0$, we have that $G_{\nu}(x, y) \simeq G_{\theta}(x, y)$. Thus we again have that $W_2 - q \in K^{\infty}(M, d\theta)$. In particular, $W_2 - q$ is Green-bounded on $(M, d\theta)$, so there exists $c' > 0$ such that

$$
\sup_{x \in M} \int_M G_\theta(x, y) |c'(W_2 - q)(y)| d\theta(y) < 1.
$$

By Lemma [4.9,](#page-14-1) $c'(W_2 - q)$ is gaugeable and thus $\Delta_{\theta} - c'(W_2 - q)$ is subcritical. I claim that there exists $c > 0$ such that $\Delta_{\theta} - c(W_2 - q) \not\geq 0$. Indeed, by hypothesis there exists $\mathcal{O} \subseteq M$ open and $\epsilon > 0$ such that $W_2 > q + \epsilon$ on \mathcal{O} . Let $\varphi \in C_c^{\infty}(M)$ be such that $\varphi \geq 0$, φ is not identically zero and $\text{supp}(\varphi) \subseteq \mathcal{O}$. Then picking $c > 0$ large such that

$$
\int_{\mathcal{O}} (\Delta_{\theta} \varphi) \varphi d\theta < c \epsilon \int_{\mathcal{O}} \varphi^2 d\theta \leq \int_{\mathcal{O}} c (W_2 - q) \varphi^2 d\theta
$$

implies that $\Delta_{\theta} - c(W_2 - q) \not\geq 0$, proving the claim.

Thus we can let $c = \sup \{c' : \Delta_\theta - c'(W_2 - q) \ge 0\}$. Clearly $\Delta_\theta - c(W_2 - q) \ge 0$. If $\Delta_{\theta} - c(W_2 - q)$ is subcritical, then repeating the proof leading up to the claim using the h-transform as well as gaugeability implies that $\Delta_{\theta} - (c + \epsilon)(W_2 - q)$ is subcritical for some $\epsilon > 0$. But this is impossible. Thus $\Delta_{\theta} - c(W_2 - q)$ is critical.

Unraveling, by Lemma [5.2](#page-15-2) we see that $\Delta_{\nu} + W_1 - q - c(W_2 - q)$ is critical and hence $+ W_1 - c(W_2 - q)$ is critical, as desired. $\Delta_{\mu} + W_1 - c(W_2 - q)$ is critical, as desired.

Remark: If for example we are under the hypotheses of Theorem [7.1,](#page-21-0) then if we take $W_1, W_2 \geq 0$ with $|W_1(x)|, |W_2(x)| \leq \langle x \rangle^{-(2+\epsilon)}$ with W_1 and W_2 not identically zero, then we

can take any $q \in C_c^{\infty}(M)$ such that $q \geq 0$ for which there exists $x \in M$ with $0 < q(x) < W_2(x)$ and apply the above to get $c > 0$ such that $\Delta_{\mu} + W_1 - c(W_2 - q)$ is critical.

7.2 More Examples

Example 7.4. The Infinite Half-Cylinder

For $n \geq 2$ let $S^n = \{x \in \mathbb{R}^{n+1} : ||x|| = 1\}$ be the *n*-dimensional sphere, with Riemannian metric inherited from \mathbb{R}^{n+1} . Let $Q^n = \{x = (x_1, \ldots, x_n) \in S^n : x_1 \leq 0\}$ be the closed hemisphere. Define a manifold $M = Q^{n+1} \cup (0, \infty) \times S^n$. This is not necessarily smooth at the juncture between Q^{n+1} and $(0, \infty) \times S^n$, but this can be smoothed out, yielding a Riemannian manifold. Let $d\mu$ be the canonical Riemannian volume, making $(M, d\mu)$ a weighted manifold.

Since M has nonnegative Ricci curvature outside a compact set, $(M, d\mu)$ satisfies (HKE). (See citation.) Let $o \in M$ in the hemisphere be a distinguished point. Note that M satisfies (RCA) with respect to *o*. We have that $V_\mu(r) \approx r^n$ for $0 < r < 1$ and $V_\mu(r) \approx r$ for $r \ge 1$. Also $V_{\mu}(r) \asymp V_{\mu}(x,r)$ uniformly in $x \in M$ and $r > 0$. Since \int_{1}^{∞} dt $\frac{dt}{V_{\mu}(\sqrt{t})}$ = $+\infty$, $(M, d\mu)$ is parabolic.

In particular we have that

$$
\widehat{H}(y) \asymp H(|y|) \asymp 1 + \left(\int_1^{|y|} \frac{sds}{V_\mu(s)}\right)_+ \asymp 2 + |y| = \langle y \rangle. \tag{7.1}
$$

Hence if $q \in C_c^{\infty}(M)$ is nonnegative and not identically zero, and $h > 0$ is a profile for $\Delta_{\mu} + q$, we have

$$
h(x) \asymp \langle x \rangle. \tag{7.2}
$$

Thus if $W \in C^{\infty}(M)$ is not identically zero such that $0 \leq W(x) \leq \langle x \rangle^{-(2+\epsilon)}$ for some $\epsilon > 0$, then if $p_{\mu}^{W}(t,x,y)$ is the heat kernel of $\Delta_{\mu} + W$ on $(M, d\mu)$ we get the heat kernel estimate

$$
\frac{c_1 \langle x \rangle \langle y \rangle}{\min(t^{n/2}, t^{1/2}) (\langle x \rangle + \sqrt{t}) (\langle y \rangle + \sqrt{t})} \exp\left(-c_2 \frac{d(x, y)^2}{t}\right) \le p_{\mu}^W(t, x, y)
$$

$$
\le \frac{c_3 \langle x \rangle \langle y \rangle}{\min(t^{n/2}, t^{1/2}) (\langle x \rangle + \sqrt{t}) (\langle y \rangle + \sqrt{t})} \exp\left(-c_4 \frac{d(x, y)^2}{t}\right)
$$

where $c_1, c_2, c_3, c_4 > 0$ are constants and $t > 0$, $x, y \in M$ are arbitrary.

The previous example may be viewed as a model manifold, which we define now. Our presentation is largely the same as that in Grigor'yan and Saloff-Coste [\[13\]](#page-28-13).

Example 7.5. Model Manifolds

A model manifold is \mathbb{R}^N , $N \geq 2$, with a Riemannian metric given in polar coordinates $(r, \theta) \in (0, +\infty) \times S^{N-1}$ by

$$
ds^2 = dr^2 + \psi(r)^2 d\theta^2 \tag{7.3}
$$

where $d\theta^2$ is the standard metric on S^{N-1} and ψ is a smooth positive function on $(0, +\infty)$. The metric ds^2 can be extended smoothly to all of \mathbb{R}^N (i.e. across the origin) under the conditions that $\psi(0) = 0, \psi'(0) = 1$, and $\psi''(0) = 0$. Given such a ψ , we let M_{ψ} denote the model manifold \mathbf{R}^{N} equipped with the metric ds^{2} . Letting $d\mu$ be the Riemannian volume measure on M_{ψ} , we obtain a weighted manifold $(M_{\psi}, d\mu)$.

Let $o \in M_{\psi}$ be the origin so that $V_{\mu}(r) = V_{\mu}(o, r)$. Due to the radial nature of the metric, $(M_{\psi}, d\mu)$ satisfies (RCA) with respect to o. We have that

$$
V_{\mu}(r) = \omega_N \int_0^r \psi(s)^{N-1} ds,
$$
\n(7.4)

where $\omega_N > 0$ is a constant depending on N. The volume of a remote ball is given by

$$
V_{\mu}(x,r) \simeq \begin{cases} r^N, & r \le \psi(|x|) \\ r\psi(|x|)^{N-1}, & r \ge \psi(|x|) \end{cases}
$$
(7.5)

By Proposition 4.10 in Grigor'yan and Saloff-Coste [\[13\]](#page-28-13), if

$$
\sup_{[r,2r]} \psi \preceq \inf_{[r,2r]} \psi,
$$

$$
\psi(r) \preceq r,
$$

and

$$
\int_0^r \psi(s)^{N-1} ds \preceq r \psi(r)^{N-1}
$$

over all $r > 0$, then $(M_{\psi}, d\mu)$ satisfies (HKE). In particular, if $\psi(r) \approx r^{\beta}$ for $r > 1$, then $(M_{\psi}, d\mu)$ satisfies (HKE) if and only if $-1/(N-1) < \beta \leq 1$.

The infinite half-cylinder Example [7.4](#page-24-1) is analogous to $\beta = 0$. The case $\beta = 1$ is analogous to \mathbf{R}^N with its Euclidean metric. By (HKE), $(M_{\psi}, d\mu)$ is parabolic if and only if \int_1^∞ dt $\frac{dt}{V_{\mu}(\sqrt{t})}$ = + ∞ , so using Equation [7.4,](#page-25-0) if $\psi(r) \asymp r^{\beta}$ for $r > 1$ with $-1/(N-1) < \beta \le 1$, then $(M_{\psi}, d\mu)$ is parabolic if and only if $\beta \leq 1/(N-1)$. In fact we have $V_{\mu}(r) \approx r^{\beta(N-1)+1}$ for $r > 1$. We assume from here on out that $-1/(N-1) < \beta \le 1/(N-1)$.

For a remote ball $B(y, r)$ with $r > 1$ and $|y| > 1$, if $r \ge \psi(|y|) \asymp |y|^{\beta}$, then $V_{\mu}(y, r) \asymp$ $r |y|^{\beta(N-1)}$. If $r \leq \psi(|y|)$, then $V_{\mu}(y,r) \asymp r^N$.

Thus we have that for $|y| > 1$,

$$
\widehat{H}(y) = 1 + \left(\int_1^{|y|^2} \frac{dt}{V_\mu(y, \sqrt{t})} \right)_+ \times 1 + \int_1^{\max(1, |y|^{2\beta})} \frac{dt}{t^{N/2}} + \int_{\max(1, |y|^{2\beta})}^{|y|^2} \frac{dt}{\sqrt{t} |y|^{\beta(N-1)}} \approx |y|^{1-\beta(N-1)}
$$

.

Similarly, if $\beta < 1/(N-1)$, then

$$
H(|y|) \asymp \langle y \rangle^{1-\beta(N-1)} \asymp \widehat{H}(y).
$$

If $\beta = 1/(N-1)$, then

$$
H(|y|) \asymp \log \langle y \rangle.
$$

In both cases we have

$$
\widehat{H}(y) \preceq H(|y|) \tag{7.6}
$$

over all $y \in M$. Notably, if $\beta < 0$, then for a fixed $r > 1$ we have that

$$
\lim_{|y| \to \infty} \frac{V_{\mu}(y,r)}{V_{\mu}(r)} = 0
$$

and yet we still have $\widehat{H}(y) \preceq H(|y|)$.

Due to $\beta \leq 1/(N-1)$, we have that for $1 \leq s < r$ we have

$$
\frac{V_{\mu}(r)}{V_{\mu}(s)} \preceq \left(\frac{r}{s}\right)^2.
$$
\n(7.7)

Putting it all together, we have that: for $-1/(N-1) < \beta \leq 1/(N-1)$ with $\psi(r) \asymp r^{\beta}$ for $r > 1$, the model manifold $(M_{\psi}, d\mu)$ is complete, non-compact, parabolic, satisfies (HKE) as well as (RCA) with respect to the origin o. By [7.6](#page-26-0) and [7.7,](#page-26-1) if $W \in C^{\infty}(M)$ is not identically zero with $0 \leq W(x) \leq \langle x \rangle^{-(2+\epsilon)}$ for some $\epsilon > 0$, then for $\beta = 1/(N-1)$, letting $p_{\mu}^{W}(t, x, y)$ be the heat kernel of $\Delta_{\mu} + W$, we get the constants $c_1, c_2, c_3, c_4 > 0$ such that

$$
\frac{c_1 \log \langle x \rangle \log \langle y \rangle}{\log^2(\langle x \rangle + \sqrt{t}) V_\mu(x, \sqrt{t})} e^{-c_2 \frac{d(x, y)^2}{t}} \le p^W(t, x, y) \le \frac{c_3 \log \langle x \rangle \log \langle y \rangle}{\log^2(\langle x \rangle + \sqrt{t}) V_\mu(x, \sqrt{t})} e^{-c_4 \frac{d(x, y)^2}{t}}.
$$

For $\beta < 1/(N-1)$, we instead get $c_1, c_2, c_3, c_4 > 0$ such that

$$
\frac{c_1 \langle x \rangle^{\sigma} \langle y \rangle^{\sigma}}{(\langle x \rangle + \sqrt{t})^{2\sigma} V_{\mu}(x,\sqrt{t})} e^{-c_2 \frac{d(x,y)^2}{t}} \leq p_{\mu}^W(t,x,y) \leq \frac{c_3 \langle x \rangle^{\sigma} \langle y \rangle^{\sigma}}{(\langle x \rangle + \sqrt{t})^{2\sigma} V_{\mu}(x,\sqrt{t})} e^{-c_4 \frac{d(x,y)^2}{t}}
$$

for all $t > 0$ and $x, y \in M_{\psi}$, where $\sigma = 1 - \beta(N - 1)$. One can write further expand using our bounds on $V_\mu(x, \sqrt{t})$ if desired.

Example 7.6. A Parabolic Manifold with Faster Than Quadratic Volume Growth

Consider the manifold \mathbb{R}^2 with weighted measure $d\mu = \log \langle x \rangle dx$, where dx is Lebesgue measure. Let $o \in \mathbb{R}^2$ be the origin so that $(\mathbb{R}^2, d\mu)$ satisfies (RCA) with respect to o. Note first that $V_{\mu}(r) \approx r^2 \log(2+r)$, so that volume grows faster than quadratically.

If $B(x, r)$ is a remote ball then $\log \langle y \rangle \approx \log \langle x \rangle$ for all $y \in B(x, r)$. This immediately yields (VD) and (PI) for remote balls in $(M, d\mu)$. Volume comparison also follows from the fact that if $r = |x|$, then $V_{\mu}(r) \approx r^2 \log(2+r) = r^2 \log \langle x \rangle \approx V_{\mu}(x, r/64)$. Therefore by

Theorem [3.5,](#page-9-2) $(M, d\mu)$ satisfies (HKE).

Since $V_\mu(r) \preceq V_\mu(y,r)$ for $0 < r \leq |y|$, we immediately have that $\widehat{H}(y) \preceq H(|y|)$. Next we have that

$$
H(|y|) = 1 + \left(\int_1^{|y|^2} \frac{dt}{V_\mu(\sqrt{t})}\right)_+ \asymp 1 + \left(\int_1^{|y|^2} \frac{dt}{t \log(2 + \sqrt{t})}\right)_+ \asymp \log \log \langle y \rangle.
$$

Since $H(|y|) \to +\infty$ as $|y| \to \infty$, $(M, d\mu)$ is parabolic. Note that $V_{\mu}(x, r) \approx r^2 \log(\langle x \rangle + r)$. Considering all of the above, if $W \in C^{\infty}(M)$ is not identically zero with $0 \leq W(x) \leq$ $\langle x \rangle^{-(2+\epsilon)}$, then we can take $0 < \delta < \epsilon$ and note that for $1 \leq s < r$,

$$
\frac{V_{\mu}(r)}{V_{\mu}(s)} \preceq \left(\frac{r}{s}\right)^{2+\delta},
$$

with constant depending on δ . Therefore we get constants $c_1, c_2, c_3, c_4 > 0$ such that, letting $p_{\mu}^{W}(t,x,y)$ be the heat kernel of $\Delta_{\mu} + W$,

$$
\frac{c_1 \log \log \langle x \rangle \log \log \langle y \rangle}{t \log(\langle y \rangle + \sqrt{t})(\log \log(\langle y \rangle + \sqrt{t}))^2} e^{-c_2 \frac{|x-y|^2}{t}} \le p_{\mu}^W(t, x, y) \le
$$

$$
\frac{c_3 \log \log \langle x \rangle \log \log \langle y \rangle}{t \log(\langle y \rangle + \sqrt{t})(\log \log(\langle y \rangle + \sqrt{t}))^2} e^{-c_4 \frac{|x-y|^2}{t}}
$$

for all $t > 0$ and $x, y \in \mathbb{R}^2$.
