#### ABSTRACT

We propose a new method based on sparse optimal discriminant clustering (SODC), by a penalty term to scoring matrix based on convex clustering. With the addition of this penalty term, it is expected to improve the accuracy of cluster identification by attaching points from the same cluster closer together and points from different clusters further apart. Moreover, we develop a novel algorithm to derive the updated formula of this scoring matrix using majorizing function. It solves the difficulty to satisfy both constraint and containing the clustering structure to the scoring matrix. We have demonstrated the numerical simulations and its an application to real data to assess the performance of the proposed method.

*Keywords* dimension reduction clustering · optimal scoring · MM algorithm · ADMM

# 1 Introduction

Dimension reduction clustering has been utilized to interpret the characteristic of large and complex data. It estimates a low dimensional space for identifying clusters, allowing efficient handling while preserving important features of high dimensional data. For this, these methods enable to facilitate the interpretation of information including visualization. Various dimension reduction clustering methods have been proposed [e.g. [Soete and Carroll, 1994,](#page-19-0) [Vichi and Kiers,](#page-19-1) [2001,](#page-19-1) [Timmerman et al., 2013,](#page-19-2) [Zhang and Dai, 2009,](#page-19-3) [Wang et al., 2016\]](#page-19-4). Among these methods, we focus on Optimal discriminant clustering (ODC) [\[Zhang and Dai, 2009\]](#page-19-3) in this study.

ODC has been proposed as an unsupervised learning method based on optimal scoring for Fisher's linear discriminant analysis (LDA) [\[Hastie et al., 1994\]](#page-19-5). Optimal scoring for LDA method uses class information with scoring matrix when reducing dimension. ODC substitutes unknown scoring matrix for this class information matrix of optimal scoring for LDA because it is not known in advance which cluster each subject belongs to. The objective function of ODC is same form as that of linear regression, and the components are defined as a linear combination of the original features. That aids to enhance interpretability. Based on this method, sparse optimal discriminant clustering (SODC) has also been proposed by [Wang et al.](#page-19-4) [\[2016\]](#page-19-4), which adds a group lasso term [\[Yuan and Lin, 2006\]](#page-19-6). ODC and SODC describe the cluster more clearly than principal components analysis [\[Wang et al., 2016\]](#page-19-4). However, the scoring matrix in ODC and SODC does not have a structure to identify cluster. It might affect the accuracy of clustering estimation. In addition,

<sup>∗</sup>Use footnote for providing further information about author (webpage, alternative address)—*not* for acknowledging funding agencies.

SODC may not describe well-separated clustering structure when reduced to a lower dimension and visualized the results.

Therefore, we propose a method in SODC by adding a penalty term based on convex clustering [\[Pelckmans et al.,](#page-19-7) [2005,](#page-19-7) [Hocking et al., 2011,](#page-19-8) [Lindsten et al., 2011\]](#page-19-9) for the scoring matrix named regularized sparse optimal discriminant clustering (RSODC). With this additional term, it is expected to improve the identification of clusters by having clusters visually attached to each other further apart than in the conventional SODC. This also allows to draw the clustering structure more clearly when the estimated results are visualized. The clustering structure in the scoring matrix is then expected to improve the classification accuracy of the clustering. Unlike [Berends et al.](#page-19-10) [\[2022\]](#page-19-10) and [Buch et al.](#page-19-11) [\[2024\]](#page-19-11), the model of the proposed method is approximated on the low dimensions, not on the original dimensions. In addition to that, we develop a new algorithm with the majorizing function [\[Hunter and Lange, 2004,](#page-19-12) [Pietersz and Groenen, 2004\]](#page-19-13) to derive the updated formula of the scoring matrix with the addition of penalty term based on convex clustering. The scoring matrix is updated from alternating direction method of multiplier (ADMM) [\[Boyd et al., 2011\]](#page-19-14), which is often used for calculating the parameters of the objective function for convex clustering. On the other hand, the proposed method has orthogonal constraint to the scoring matrix as the conventional SODC does. Therefore, the proposed method needs to satisfy orthogonal constraint to the scoring matrix while retaining clustering structure. In the process of ADMM, the updated formula of the scoring matrix is derived with orthogonal procrustes analysis [\[Schönemann, 1966\]](#page-19-15). To solve this problem, the scoring matrix needs to be expressed only in linear form, however, it also has a quadratic form. Therefore, we derive the majorizing function for the scoring matrix. This algorithm achieves both the constraint in the scoring matrix and retaining clustering structure simultaneously.

In Section 2, we first explain the study related to the proposed method. Then, we present the objective function and its algorithm of the proposed method in Section 3. In Section 4, we demonstrate the numerical simulations, and report the application to the real gene data in Section 5. Finally, we conclude the discussion in Section 6.

# 2 Related methods

The proposed method is extended based on sparse optimal discriminant clustering (SODC). We first explain related methods before presenting the proposed method.

#### 2.1 Sparse optimal discriminant clustering (SODC)

Sparse optimal discriminant clustering (SODC) [\[Wang et al., 2016\]](#page-19-4) has been developed with sparse penalty from optimal discriminant clustering (ODC) [\[Zhang and Dai, 2009\]](#page-19-3). ODC is a method to be unsupervised from optimal scoring for the Fisher's linear discriminant analysis (LDA) [\[Hastie et al., 1994\]](#page-19-5). Given data matrix  $X=(x_1,x_2,\cdots,x_n)^\top\in\mathbb{R}^{n\times p}$ , centering matrix  $H_n = I_n - \frac{1}{n} \mathbf{1}_n \mathbf{1}_n^\top \in \mathbb{R}^{n \times n}$  where  $\mathbf{1}_n = (1, 1, \dots, 1)$  and  $I_n \in \mathbb{R}^{n \times n}$  is identity matrix, and known indicator matrix for class information  $\mathbf{E} = (e_{i\ell}) \in \mathbb{R}^{n \times k}$   $(i = 1, 2, \cdots, n; \ell = 1, 2, \cdots k)$ , where  $e_{i\ell} = 1$  if subject i belongs to the cluster  $\ell$ , otherwise  $e_{i\ell} = 0$ , the objective function of optimal scoring for LDA is as follow:

$$
\min_{\boldsymbol{B}, \boldsymbol{\theta}} \frac{1}{2} \| \boldsymbol{E}\boldsymbol{\theta} - \boldsymbol{H}_n \boldsymbol{X}\boldsymbol{B} \|_F^2 + \eta_2 \| \boldsymbol{B} \|_F^2
$$

s.t.  $\boldsymbol{\theta}^\top \boldsymbol{E}^\top \boldsymbol{E} \boldsymbol{\theta} = \boldsymbol{I}_{k-1}$  and  $(\boldsymbol{E} \boldsymbol{\theta})^\top \boldsymbol{1} = \boldsymbol{0}$ ,

where,  $\eta_2$   $(\eta_2 \ge 0)$  is a tuning parameter, k is the number of class, and  $\|\cdot\|_F$  is Frobenius norm.  $\theta \in \mathbb{R}^{k \times (k-1)}$  is a scoring matrix, and its  $\ell$ th row indicates score for  $\ell$ th class.  $\mathbf{B} = (\beta_1, \beta_2, \cdots, \beta_p)^\top \in \mathbb{R}^{p \times (k-1)}$  is weight for each variable to interpret  $XB$ , the coordinates in low-dimensional space, which is estimated in the form of a regression with E $\theta$  as the objective variable. Each data  $x_i$  is assumed to belong to one group.

In unsupervised learning, [Zhang and Dai](#page-19-3) [\[2009\]](#page-19-3) proposed optimal discriminant clustering (ODC) based on this optimal scoring for LDA. Class information is already obtained in the supervised method, whereas in unsupervised learning method, no information is given a priori as to which cluster a subject belongs. Therefore, ODC modified the class information variables  $\bm E\bm\theta$  in optimal scoring for LDA to  $\bm Y^\dagger=(\bm y_1^\dagger,\bm y_2^\dagger,\cdots,\bm y_n^\dagger)^\top\in\mathbb R^{n\times (k-1)}$  as unknown scoring matrix. This objective function is

<span id="page-1-0"></span>
$$
\min_{\mathbf{B},\mathbf{Y}^{\dagger}}\frac{1}{2}\|\mathbf{Y}^{\dagger}-\mathbf{H}_{n}\mathbf{X}\mathbf{B}\|_{F}^{2}+\eta_{2}\|\mathbf{B}\|_{F}^{2}
$$
\n(1)

s.t.  $\boldsymbol{Y}^{\dagger\top}\boldsymbol{Y}^{\dagger} = \boldsymbol{I}_{k-1}$  and  $\boldsymbol{Y}^{\dagger\top}\boldsymbol{1} = \boldsymbol{0}$ .

ODC also has the same constraints on  $Y^{\dagger}$  as  $E\theta$  in the optimal scoring for LDA. With Eq. [\(1\)](#page-1-0), [Wang et al.](#page-19-4) [\[2016\]](#page-19-4) have proposed to extend it with sparse penalty, and its objective function is

<span id="page-2-0"></span>
$$
\min_{\mathbf{B},\mathbf{Y}^{\dagger}}\frac{1}{2}\|\mathbf{Y}^{\dagger}-\mathbf{H}_{n}\mathbf{X}\mathbf{B}\|_{F}^{2}+\eta_{2}\|\mathbf{B}\|_{F}^{2}+\eta_{1}\sum_{j=1}^{p}\|\beta_{j}\|_{2}
$$
\n(2)

s.t.  $\boldsymbol{Y}^{\dagger\top}\boldsymbol{Y}^{\dagger}=\boldsymbol{I}_{(k-1)}$  and  $\boldsymbol{Y}^{\dagger\top}\boldsymbol{1}=\boldsymbol{0}$ .

Here,  $\eta_1$  ( $\eta_1 \ge 0$ ) and  $\eta_2$  ( $\eta_2 \ge 0$ ) are tuning parameters, and  $\|\cdot\|_2$  is the Euclidean norm. SODC has group lasso penalty [\[Yuan and Lin, 2006\]](#page-19-6) for variable selection. Eq. [\(2\)](#page-2-0), is used to obtain the final solution by alternately updating the parameters,  $Y^{\dagger}$  by singular value decomposition and  $B$  in a manner similar to updating the group lasso [\[Yuan and](#page-19-6) [Lin, 2006\]](#page-19-6).

# 2.2 Convex clustering

Convex clustering [\[Pelckmans et al., 2005,](#page-19-7) [Hocking et al., 2011,](#page-19-8) [Lindsten et al., 2011\]](#page-19-9) is a method for dividing data points into clusters using convex optimization to achieve stable clustering. It detects the clustering structure by finding parameters that minimize an objective function, which includes a penalty term based on the distances between data points.

Given data matrix  $X \in \mathbb{R}^{n \times p}$ , the objective function of convex clustering is as follows:

$$
\min_{\mathbf{V} \in \mathbb{R}^{n \times p}} \frac{1}{2} \|\mathbf{X} - \mathbf{V}\|_{2}^{2} + \gamma \sum_{i < j} \alpha_{i,j} \|\mathbf{v}_{i} - \mathbf{v}_{j}\|_{2} \tag{3}
$$

where  $\gamma$  ( $\gamma \ge 0$ ) is a tuning parameter.  $\mathbf{V} = (\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n) \in \mathbb{R}^{n \times p}$  is the cluster centroid, and  $\mathbf{v}_i \in \mathbb{R}^p$  indicates the *i*th row of  $\vec{V}$ .  $\alpha_{i,j}$  ( $\alpha_{i,j} \ge 0$ ) is the weight. There are various ways to calculate this weight [\[Hocking et al., 2011,](#page-19-8) [Chi and Lange, 2015\]](#page-19-16). In this study, we apply the following weight proposed by [Chi and Lange](#page-19-16) [\[2015\]](#page-19-16):

<span id="page-2-4"></span><span id="page-2-1"></span>
$$
\alpha_{i,j} = \iota_{i,j}^{m^*} \exp(-\phi^* \| \boldsymbol{x}_i - \boldsymbol{x}_j \|_2^2)
$$
\n(4)

where  $\iota_{i',j}^{m^*}$  returns 1 if j is among i's  $m^*$  nearest neighbors or if i is among j's  $m^*$  nearest neighbors, otherwise returns 0.  $\phi^*$   $(\phi^* \ge 0)$  is a tuning parameter. For the second term of Eq. [\(3\)](#page-2-1), convex clustering with  $L_1$ ,  $L_2$ , and  $L_\infty$  penalties for each are proposed [\[Boyd et al., 2011\]](#page-19-14), but we treat  $L_2$  norm in this study. To solve this optimization problem, the alternating direction method of multipliers (ADMM) [\[Boyd et al., 2011,](#page-19-14) [Chi and Lange, 2015\]](#page-19-16) is adapted. For the implementation of ADMM, Eq. [\(3\)](#page-2-1) can be firstly rewritten as the following equivalent equation:

$$
\min_{\boldsymbol{V} \in \mathbb{R}^{n \times p}} \frac{1}{2} \|\boldsymbol{X} - \boldsymbol{V}\|_2^2 + \gamma \sum_{l \in \varepsilon} \alpha_l \|\boldsymbol{v}_l^{\dagger}\|_2, \tag{5}
$$

s.t.  $(v_i - v_j) - v_i^{\dagger} = 0$ . Here,  $l = (i, j)$  is a pair of subject, and  $\varepsilon = \{l = (i, j) : \alpha_l > 0, i < j, i, j = 1, 2, \cdots, n\}$ .  $v_l^{\dagger}$  is the difference between  $v_i$  and  $v_j$ .

# 3 Regularized Sparse Optimal Discriminant Clustering (RSODC)

We introduce the proposed method named Regularized Sparse Optimal Discriminant Clustering (RSODC). In [3.1,](#page-2-2) we describe the objective function of the proposed. Then, we explain overall of the algorithm in [3.2.](#page-3-0) After that, we introduce updated formula for each parameters in [3.3](#page-4-0) to [3.5.](#page-8-0)

## <span id="page-2-2"></span>3.1 Optimization problem of RSODC

We propose a new method for SODC by adding a regularization term used in convex clustering in order to provide more discriminative optimal scoring of SODC. By adding this regularization term, ADMM algorithm [\[Boyd et al., 2011,](#page-19-14) [Chi](#page-19-16) [and Lange, 2015\]](#page-19-16) is employed. To handle this problem easier, the proposed method needs to be transformed into the form of augmented Lagrangian function. In this subsection, we first define the optimization problem of the proposed method, then show the process of the transformation for its augmented Lagrangian function.

Given data X and centering matrix  $H_n$ , the optimization problem is defined as

<span id="page-2-3"></span>
$$
\min_{\mathbf{B},\mathbf{Y}^{\dagger}}\frac{1}{2}\|\mathbf{Y}^{\dagger}-\mathbf{H}_{n}\mathbf{X}\mathbf{B}\|_{F}^{2}+\eta_{2}\|\mathbf{B}\|_{F}^{2}+\eta_{1}\sum_{j=1}^{p}\|\beta_{j}\|_{2}+\gamma\sum_{i\n(6)
$$

s.t.  $\boldsymbol{Y}^{\dagger\top}\boldsymbol{Y}^{\dagger} = \boldsymbol{I}_{k-1}$  and  $\boldsymbol{Y}^{\dagger\top}\boldsymbol{1} = \boldsymbol{0}$ .

Here,  $\eta_1(\eta_1 \geq 0), \eta_2(\eta_2 \geq 0)$  and  $\gamma(\gamma \geq 0)$  are tuning parameters.  $\mathbf{B} = (\beta_1, \beta_2, \dots, \beta_p)^\top =$  $(\beta_{(1)}, \beta_{(2)}, \cdots, \beta_{(k-1)}) \in \mathbb{R}^{p \times (k-1)}$  is weight for each variable. The first to the third terms of Eq. [\(6\)](#page-2-3) are the same terms as SODC [\[Wang et al., 2016\]](#page-19-4). We add a penalty term of convex clustering [\[Hocking et al., 2011\]](#page-19-8) to SODC as a penalty term to  $Y^{\dagger} \in \mathbb{R}^{n \times (k-1)}$ , corresponding to the fourth term of Eq. [\(6\)](#page-2-3). With this term, similar subjects are attached closer to each other.  $\alpha_{i,j} = \alpha_l(\alpha_l \ge 0)$  is the weight, which is calculated using Eq. [\(4\)](#page-2-4). When  $\alpha_{i,j}$  is larger, the value of  $L_2$  norm of  $y_i^{\dagger} - y_j^{\dagger}$  is close to 0.

Next, we describe the approach to solve Eq. [\(6\)](#page-2-3). The proposed method employs alternating direction method of multipliers (ADMM) algorithm [\[Boyd et al., 2011\]](#page-19-14) used for solving convex clustering [\[Chi and Lange, 2015\]](#page-19-16). First, the proposed method is rewritten as

$$
\min_{\mathbf{B}, \mathbf{Y}, \mathbf{V}^{\dagger}, \mathbf{\Lambda}} \frac{1}{2} \|\mathbf{Y} - \mathbf{H}_n \mathbf{X} \mathbf{B}\|_F^2 + \eta_2 \|\mathbf{B}\|_F^2 + \eta_1 \sum_{j=1}^p \|\beta_j\|_2 + \gamma \sum_{l \in \varepsilon} \alpha_l \|\mathbf{v}_l^{\dagger}\|_2, \tag{7}
$$

s.t.

$$
\mathbf{y}_i - \mathbf{y}_j = \mathbf{v}_l^{\dagger},\tag{8}
$$

$$
\boldsymbol{Y}^{\top}\boldsymbol{Y} = \boldsymbol{I}_{k-1}, \text{and} \tag{9}
$$

<span id="page-3-5"></span><span id="page-3-4"></span><span id="page-3-3"></span><span id="page-3-2"></span><span id="page-3-1"></span>
$$
Y^{\top}1 = 0. \tag{10}
$$

 $\boldsymbol{V}^\dagger = (\boldsymbol{v}_1^\dagger, \boldsymbol{v}_2^\dagger, \cdots, \boldsymbol{v}_{|_{\ell}}^\dagger)$  $|E|_{\epsilon}|^{\top}$ , where  $|\cdot|$  is a cardinality of a set, is the difference between two cluster centroids.  $Y^{\dagger}$ represents optimal scoring in the original optimization problem in Eq. [\(6\)](#page-2-3), whereas the problem of estimating  $Y^{\dagger}$ is treated as that to be solved by decomposing into  $\mathbf{Y} = (\mathbf{y}_{(1)}, \mathbf{y}_{(2)}, \cdots, \mathbf{y}_{(k-1)}) \in \mathbb{R}^{n \times (k-1)}$   $(\mathbf{y}_{(j)} \in \mathbb{R}^n, j = 1)$  $1, 2, \dots, k-1$  and  $V^{\dagger}$  in Eq. [\(7\)](#page-3-1). Solving Eq. (7) is equivalent to minimizing the augmented Lagrangian function, which can be defined as

$$
\min_{\boldsymbol{B}, \boldsymbol{Y}, \boldsymbol{V}^{\dagger}, \boldsymbol{\Lambda}} \frac{1}{2} \|\boldsymbol{Y} - \boldsymbol{H}_n \boldsymbol{X} \boldsymbol{B}\|_F^2 + \eta_2 \|\boldsymbol{B}\|_F^2 + \sum_{j=1}^p \|\beta_j\|_2 + \gamma \sum_{l \in \varepsilon} \alpha_l \|\boldsymbol{v}_l^{\dagger}\|_2
$$

$$
+ \sum_{l \in \varepsilon} \boldsymbol{\lambda}_l^{\top} (\boldsymbol{v}_l^{\dagger} - \boldsymbol{y}_i + \boldsymbol{y}_j) + \frac{\rho}{2} \sum_{l \in \varepsilon} \|\boldsymbol{v}_l^{\dagger} - \boldsymbol{y}_i + \boldsymbol{y}_j\|_2^2, \tag{11}
$$

where  $\rho(\rho > 0)$  is a tuning parameter, and  $\Lambda = (\lambda_1, \lambda_2, \cdots, \lambda_{|\varepsilon|})^\top$  is Lagrangian multiplier.

# <span id="page-3-0"></span>3.2 Algorithm

In this subsection, the general framework of the algorithm of the proposed method is presented. **STEP 2.** contains further update steps within it resulting from the addition of the penalty term.

As used in SODC, alternating least squares (ALS) method is used to update B and  $Y^{\dagger}$ . In updating  $Y^{\dagger}$ , alternating direction method of multipliers (ADMM) [\[Boyd et al., 2011,](#page-19-14) [Chi and Lange, 2015\]](#page-19-16) is used. The overall algorithm is the following steps:

#### Algorithm of the proposed method

**STEP 0.** Set initial value of  $B, Y^{\dagger}, V^{\dagger}$ , and  $\Lambda$ .

**STEP 1.** Update *B* under given  $Y^{\dagger}$ .

**STEP 2.** Update  $Y^{\dagger}$  under given B by using ADMM algorithm.

**STEP 2-1.** Update Y under given  $V^{\dagger}$  and  $\Lambda$ .

**STEP 2-2.** Update  $V^{\dagger}$  under given Y and  $\Lambda$ .

**STEP 2-3.** Update  $\Lambda$  under given Y and  $V^{\dagger}$ .

STEP 2-4. Repeat STEP 2-1. to STEP 2-3. until the value of the objective function converges.

STEP 3. Repeat STEP 1. and STEP 2. until the value of the objective function converges.

 $\textbf{STEP 4.} \text{ Calculate } \bm{G}^* = (\bm{g}_1^*, \bm{g}_2^*, \cdots, \bm{g}_n^*)^\top = \bm{H}_n \bm{X} \hat{\bm{B}}.$ 

**STEP 5.** Apply *k*-means to  $G^*$ .

**STEP 6.** Obtain the clustering result of  $g_i^*$ .

In STEP 2-1., the proposed method needs to satisfy constrains for SODC, in Eq. [\(9\)](#page-3-2) and Eq. [\(10\)](#page-3-3), and the constraint for the penalty term on Y in Eq. [\(8\)](#page-3-4) simultaneously, however, it is difficult to solve this problem with applying the updated procedure in the conventional SODC directly. Therefore, we propose a novel algorithm for  $Y$  by deriving the majorizing function.

The updated formula of  $\bm{B}$  will be explained in [3.3.](#page-4-0) Then, the deriving the majorization function for updated formula  $\bm{Y}$ will be presented in [3.4.](#page-5-0) After that, the update procedure for  $Y^{\dagger}$  will be described in [3.5.](#page-8-0) Hyperparameter  $\eta_1, \eta_2, \gamma$ , and  $\rho$  are determined by the modified version of cross-validation based on the kappa

coefficient [\[Cohen, 1960\]](#page-19-17) proposed by [\[Wang et al., 2016,](#page-19-4) [Sun et al., 2013\]](#page-19-18) with the idea of clustering stability.

# <span id="page-4-0"></span>3.3 Update formula of B

In this subsection, we explain the updated formula for B. This uses coordinate descent algorithm [\[Friedman et al.,](#page-19-19) [2007\]](#page-19-19) for the group lasso [\[Yuan and Lin, 2006\]](#page-19-6) update procedure.

First, in order to update in the form of linear regression, the terms on  $\bf{B}$  are transposed in vector form. In this study, we set  $\eta_2 = 0$ . For the terms related to **B** in Eq. [\(6\)](#page-2-3),

<span id="page-4-1"></span>
$$
\|\mathbf{Y} - \mathbf{H}_n \mathbf{X} \mathbf{B}\|_F^2 + \eta_2 \|\mathbf{B}\|_F^2 + \eta_1 \sum_{j=1}^p \|\beta_j\|_2
$$
  

$$
\Longleftrightarrow \|\mathbf{y}^* - \mathbf{Z}^* \boldsymbol{\beta}^*\|_F^2 + \eta_1 \sum_{j=1}^p \|\beta_j\|_2,
$$
 (12)

 $\text{where} \; vec(\boldsymbol{Y}) \;=\; \boldsymbol{y}^{\ddagger} \;=\; \big(\boldsymbol{y}_{(1)}^{\top}, \boldsymbol{y}_{(2)}^{\top}, \cdots, \boldsymbol{y}_{(k-1)}^{\top} \big)^{\top} \;\in\; \mathbb{R}^{n(k-1)\times 1}, \; vec(\boldsymbol{B}) \;=\; \boldsymbol{\beta}^{\ast} \;=\; \big(\boldsymbol{\beta}_{(1)}^{\top}, \boldsymbol{\beta}_{(2)}^{\top}, \cdots, \boldsymbol{\beta}_{(k-1)}^{\top} \big)^{\top} \;\in\;$  $\mathbb{R}^{p(k-1)\times 1}$ , and

$$
Z^{\ddagger} = \left(\begin{array}{cccc} Z & O & \cdots & O \\ O & Z & \cdots & O \\ \vdots & \vdots & \ddots & \vdots \\ O & O & \cdots & Z \end{array}\right),\ Z = (z_{(1)}, z_{(2)}, \cdots, z_{(p)}), \text{where } H_n X = Z.
$$

Then, we set  $y^*$  and  $Z^*$  as follows:

$$
\boldsymbol{y}^* = \left(\begin{array}{c} \boldsymbol{y}^{\ddagger} \\ \boldsymbol{0}_{p(k-1)} \end{array}\right), \ \boldsymbol{Z}^* = \left(\begin{array}{c} \boldsymbol{Z}^{\ddagger} \\ \sqrt{\eta_2} \boldsymbol{I}_{p(k-1)} \end{array}\right).
$$

This algorithm is updated for every  $\beta_j$   $(j = 1, 2, \dots, p)$ . Here,  $\mathbb{Z}_j^* \in \mathbb{R}^{(n+p)(k-1)\times (k-1)}$  is submatrix of  $\mathbb{Z}^*$ corresponding to *j*th variables of  $X$ .

**Proposition 1.** Given  $Y, Z^*, \eta_1$  ( $\eta_1 \ge 0$ ),  $\eta_2$  ( $\eta_2 \ge 0$ ),  $\nu$  ( $\nu > 0$ ), the updated formula for  $B$  is derived as follows:

<span id="page-4-3"></span>
$$
\beta_j \leftarrow \begin{cases} \phi\bigg(1 - \frac{\nu\eta_1}{\|\phi\|_2}\bigg), & (\|\phi\|_2 > \nu\eta_1) \\ \mathbf{0}, & (\|\phi\|_2 \leq \nu\eta_1) \end{cases}
$$
(13)

where  $\phi = \beta_j + \nu Z_j^{*T} (r_j - Z_j^* \beta_j), r_j = y^* - \sum_{o \neq j} Z_o \beta_o$ , and  $\nu$  is a threshold parameter for updating.

*Proof.* For any  $j$ , we obtain the following equation from Eq. [\(12\)](#page-4-1):

<span id="page-4-2"></span>
$$
\left\|\boldsymbol{y}^* - \left(\boldsymbol{Z}_j^*\boldsymbol{\beta}_j + \sum_{o \neq j} \boldsymbol{Z}_o^*\boldsymbol{\beta}_o\right)\right\|_F^2 + \eta_1 \|\boldsymbol{\beta}_j\|_2.
$$
 (14)

When  $r_j = y^* - \sum_{o \neq j} Z_o \beta_o$ , Eq. [\(14\)](#page-4-2) can be rewritten as

<span id="page-5-1"></span>
$$
\left\| \bm{r}_j - \bm{Z}_j^* \bm{\beta}_j \right\|_F^2 + \eta_1 \|\bm{\beta}_j\|_2.
$$
 (15)

Since Eq. [\(15\)](#page-5-1) has the same equation as the conventional group lasso, it can be solved using the proximal gradient method for group lasso. In some given  $\beta_i$ , Eq. [\(15\)](#page-5-1) can be divided respectively into the differentiable terms and the other items.

<span id="page-5-5"></span><span id="page-5-2"></span>
$$
\begin{cases}\nf(\beta_j) = \left\| \mathbf{r}_j - \mathbf{Z}_j^* \beta_j \right\|_F^2 \\
g(\beta_j) = \eta_1 \|\beta_j\|_2\n\end{cases}
$$
\n(16)

First,  $f(\beta_j)$  differentiated by  $\beta_j$  can be obtain  $-Z_j^{*\top}r_j+Z_j^{*\top}Z_j^*\beta_j$ , and the gradient for  $f(\beta_j)$  is as follows, and let this formula be  $\phi$ .

<span id="page-5-3"></span>
$$
\phi \equiv \beta_j - \nu(-\mathbf{Z}_j^{*T} \mathbf{r}_j + \mathbf{Z}_j^{*T} \mathbf{Z}_j^* \beta_j)
$$
  
=  $\beta_j + \nu \mathbf{Z}_j^{*T} (\mathbf{r}_j - \mathbf{Z}_j^* \beta_j)$  (17)

Then, with Eq. [\(17\)](#page-5-2), the proximal operator of  $g(\beta_i)$  is as follows:

$$
\mathbf{prox}_{\nu g}(\boldsymbol{\phi}) = \underset{\boldsymbol{\beta}_j}{\text{argmin}} \left( \nu \eta_1 \| \boldsymbol{\beta}_j \|_2 + \frac{1}{2} \| \boldsymbol{\beta}_j - \boldsymbol{\phi} \|_2^2 \right). \tag{18}
$$

When  $\phi \neq 0$ , Eq. [\(18\)](#page-5-3) is differentiated by  $\beta_i$ , and is assumed as 0.

$$
\nu \eta_1 \frac{\beta_j}{\|\beta_j\|_2} + (\beta_j - \phi) = 0
$$
\n
$$
\Leftrightarrow \qquad \beta_j \left( 1 + \nu \eta_1 \frac{1}{\|\beta_j\|_2} \right) = \phi \qquad (i)
$$
\n
$$
\Leftrightarrow \qquad \left( 1 + \nu \eta_1 \frac{1}{\|\beta_j\|_2} \right)^{\top} \beta_j^{\top} \beta_j \left( 1 + \nu \eta_1 \frac{1}{\|\beta_j\|_2} \right) = \phi^{\top} \phi
$$
\n
$$
\Leftrightarrow \qquad \left( 1 + \nu \eta_1 \frac{1}{\|\beta_j\|_2} \right)^2 \|\beta_j\|_2^2 = \|\phi\|_2^2
$$
\n
$$
\Leftrightarrow \qquad \left( 1 + \nu \eta_1 \frac{1}{\|\beta_j\|_2} \right) \|\beta_j\|_2 = \|\phi\|_2
$$
\n
$$
\Leftrightarrow \qquad \|\beta_j\|_2 + \nu \eta_1 = \|\phi\|_2
$$
\n
$$
\Leftrightarrow \qquad \|\beta_j\|_2 = \|\phi\|_2 - \nu \eta_1 \qquad (ii)
$$

Therefore, substitute Eq.(ii) into Eq.(i).

$$
\beta_j \left( 1 + \nu \eta_1 \frac{1}{\|\phi\|_2 - \nu \eta_1} \right) = \phi
$$
  
\n
$$
\Leftrightarrow \beta_j \left( \frac{\|\phi\|_2 - \nu \eta_1 + \nu \eta_1}{\|\phi\|_2 - \nu \eta_1} \right) = \phi
$$
  
\n
$$
\Leftrightarrow \beta_j = \phi \left( 1 - \frac{\nu \eta_1}{\|\phi\|_2} \right)
$$

<span id="page-5-4"></span> $\Box$ 

# <span id="page-5-0"></span>3.4 Deriving the majorizing function for updated formula of  $Y$

Before explaining updated formula for  $Y^{\dagger}$ , we present a novel algorithm to derive updated formula for  $Y$  by using majorizing function, which corresponds to **STEP 2-1.** in this subsection.  $Y^{\dagger}$  is updated by alternately solving for the minimization of Y,  $V^{\dagger}$ , and  $\Lambda$  using the ADMM algorithm. We prove that the updated formula of Y is equivalent to the orthogonal procrustes problem [\[Schönemann, 1966\]](#page-19-15) for a certain matrix  $D \in \mathbb{R}^{n \times (k-1)}$ . Here, we briefly explain the orthogonal procrustes problem. For  $D$ , the optimization problem of the orthogonal procrustes analysis is

$$
\min_{Y} \|\mathbf{Y} - \mathbf{D}\|_{F}^{2},\tag{19}
$$

s.t.  $\boldsymbol{Y}^\top \boldsymbol{Y} = \boldsymbol{I}$ .

For this problem, Y to minimize Eq. [\(19\)](#page-5-4) can be  $Y = LR^{\top}$ , where the singular value decomposition  $D = L\Sigma R^{\top}$ . Here, L is left singular matrix, R is right singular matrix, and  $\Sigma$  is singular value matrix. Expanding Eq. [\(19\)](#page-5-4), the terms related to  $\boldsymbol{Y}$  are

$$
\|\mathbf{Y} - \mathbf{D}\|_{F}^{2} = \text{tr}(\mathbf{Y}^{\top}\mathbf{Y}) - 2\text{tr}(\mathbf{Y}^{\top}\mathbf{D}) + \text{const},\tag{20}
$$

where const is constant value. Eq.  $(20)$  can be solved as follows:

<span id="page-6-2"></span><span id="page-6-1"></span><span id="page-6-0"></span> $Y \leftarrow LR^{\top}.$ 

where L and R come from the singular value decomposition from  $D = L\Sigma R^{\top}$ .

Now we show the procedure for deriving the updated formula for  $Y$  from the proposed method using the orthogonal procrustes analysis, when other parameters are given. The terms containing  $\boldsymbol{Y}$  in Eq. [\(11\)](#page-3-5) can be rewritten as follows:

$$
\frac{1}{2} \|\mathbf{Y} - \mathbf{H}_n \mathbf{X} \mathbf{B}\|_F^2 + \sum_{l \in \varepsilon} \boldsymbol{\lambda}_l^\top (\mathbf{v}_l^\dagger - \mathbf{y}_i + \mathbf{y}_j) + \frac{\rho}{2} \sum_{l \in \varepsilon} \|\mathbf{v}_l^\dagger - \mathbf{y}_i + \mathbf{y}_j\|_2^2
$$
\n
$$
= \frac{1}{2} \|\mathbf{Y} - \mathbf{X}^\dagger\|_F^2 + \sum_{l \in \varepsilon} \boldsymbol{\lambda}_l^\top (\mathbf{v}_l^\dagger - \mathbf{Y}^\top \mathbf{g}_l) + \frac{\rho}{2} \sum_{l \in \varepsilon} \|\mathbf{v}_l^\dagger - \mathbf{Y}^\top \mathbf{g}_l\|_2^2.
$$
\n(21)

where  $H_nXB = X^{\dagger}$  and  $y_i - y_j = Y^{\top}g_l$ . Here,  $g_l = (g_{1l}, g_{2l}, \cdots, g_{nl})^{\top}$ , where  $g_{il} = 1, g_{jl} = -1$ , and  $g_{m^{\dagger}l} = 0$   $(m^{\dagger} \neq i, j)$ .

From Eq. [\(21\)](#page-6-1), we have

$$
\frac{1}{2} \|\mathbf{Y} - \mathbf{X}^{\dagger}\|_{F}^{2} + \sum_{l \in \varepsilon} \boldsymbol{\lambda}_{l}^{\top} (\mathbf{v}_{l}^{\dagger} - \mathbf{Y}^{\top} \mathbf{g}_{l}) + \frac{\rho}{2} \sum_{l \in \varepsilon} \|\mathbf{v}_{l}^{\dagger} - \mathbf{Y}^{\top} \mathbf{g}_{l}\|_{2}^{2} \n= -\operatorname{tr}(\mathbf{Y}^{\top} \mathbf{X}^{\dagger}) - \operatorname{tr} \Big( \sum_{l \in \varepsilon} \boldsymbol{\lambda}_{l}^{\top} \mathbf{Y}^{\top} \mathbf{g}_{l} \Big) - \rho \operatorname{tr} \Big( \sum_{l \in \varepsilon} \mathbf{Y}^{\top} \mathbf{g}_{l} \mathbf{v}_{l}^{\dagger} \Big) + \frac{\rho}{2} \operatorname{tr} \Big( \sum_{l \in \varepsilon} \mathbf{Y}^{\top} \mathbf{g}_{l} \mathbf{g}_{l}^{\top} \mathbf{Y} \Big) + \text{const},
$$
\n(22)

where const is terms not related to Y. The terms related to Y of Eq.  $(22)$  can be calculated as

$$
-tr(\mathbf{Y}^{\top}\mathbf{X}^{\dagger}) - tr(\mathbf{Y}^{\top}\sum_{l \in \varepsilon} g_l \lambda_l^{\top}) - \rho tr(\mathbf{Y}^{\top}\sum_{l \in \varepsilon} g_l v_l^{\top}) + \frac{\rho}{2} tr(\mathbf{Y}^{\top}\sum_{l \in \varepsilon} g_l g_l^{\top} \mathbf{Y})
$$
  
= 
$$
- tr(\mathbf{Y}^{\top}(\mathbf{X}^{\dagger} + \sum_{l \in \varepsilon} g_l \lambda_l^{\top} + \rho \sum_{l \in \varepsilon} g_l v_l^{\top}) + \frac{\rho}{2} tr(\mathbf{Y}^{\top}\sum_{l \in \varepsilon} g_l g_l^{\top} \mathbf{Y}).
$$
 (23)

The first, second and third terms of Eq. [\(23\)](#page-6-3) can be expressed as the form of linear function of Y such as  $tr(Y^{\top}D)$ , where  $D$  is a certain matrix. However, the fourth term of Eq. [\(23\)](#page-6-3) is quadratic form, not linear function. It is difficult to solve this orthogonal procrustes analysis, unless transforming this term into the linear form. In order to overcome this problem, the proposed method uses majorizing function [\[Hunter and Lange, 2004,](#page-19-12) [Pietersz and Groenen, 2004\]](#page-19-13).

Majorizing function is a function defined in majorization-minimization (MM) algorithm. MM algorithm is an algorithm that can optimize the objective function without hyper parameters. Let  $\theta \in \mathbb{R}^p$  denote the parameter of the real-valued objective function of interest  $f : \mathbb{R}^p \to \mathbb{R}$ .  $\theta^{(t)}$  represents a fixed value of parameter  $\theta$ , that is, i.e.  $\theta^{(t)}$  denotes the estimated  $\theta$  in the tth step in the algorithm.  $g : \mathbb{R}^p \to \mathbb{R}$  depending on  $\theta^{(t)}$  is also a real-valued function such that the updated formula can be easily derived. This function  $g(\theta|\theta^{(t)})$  is then defined as the majorizing function of  $f(\theta)$  in  $\theta^{(t)}$ , when the following two conditions are satisfied:

<span id="page-6-4"></span><span id="page-6-3"></span>
$$
g(\boldsymbol{\theta}|\boldsymbol{\theta}^{(t)}) \ge f(\boldsymbol{\theta}) \text{ for all } \boldsymbol{\theta},
$$

$$
g(\boldsymbol{\theta}^{(t)}|\boldsymbol{\theta}^{(t)}) = f(\boldsymbol{\theta}^{(t)}).
$$

We derive the majorizing function to Eq. [\(23\)](#page-6-3) as the same manner of in [Pietersz and Groenen](#page-19-13) [\[2004\]](#page-19-13) and [Touw et al.](#page-19-20) [\[2022\]](#page-19-20).

<span id="page-6-5"></span>**Lemma 1.** Given  $Y, C, Q$ , and  $\omega$ , the following inequality holds:

$$
\operatorname{tr}(\boldsymbol{Y}^{\top}\boldsymbol{C}\boldsymbol{Y}) \le 2\omega - 2\operatorname{tr}(\boldsymbol{Y}^{\top}(\omega\boldsymbol{I} - \boldsymbol{C})\boldsymbol{Q} - \operatorname{tr}(\boldsymbol{Q}^{\top}\boldsymbol{C}\boldsymbol{Q}),
$$
\n(24)

where  $C = \frac{\rho}{2} \sum_{l \in \varepsilon} g_l g_l^{\top}$ , Q is Y in the previous step,  $\omega (\omega > 0)$  is the largest eigenvalue of C, and  $C - \omega I$  is negative semidefinite.

*Proof.* For any  $y_{o^{\dagger}}$ , in the case that  $y_{o^{\dagger}}^{\top} y_{o^{\dagger}} = q_{o^{\dagger}}^{\top} q_{o^{\dagger}} = 1$ , the following inequality holds:

$$
\boldsymbol{y}_{o^\dagger}^\top \boldsymbol{C} \boldsymbol{y}_{o^\dagger} \leq 2 \omega - 2 \boldsymbol{y}_{o^\dagger}^\top (\omega \boldsymbol{I} - \boldsymbol{C}) \boldsymbol{q}_{o^\dagger} - \boldsymbol{q}_{o^\dagger}^\top \boldsymbol{C} \boldsymbol{q}_{o^\dagger}.
$$

Since it holds for any  $y_{o^{\dagger}}$ , the following holds:

$$
\sum_{\sigma^{\dagger}=1}^{d} \bm{y}_{\sigma^{\dagger}}^{\top} \bm{C} \bm{y}_{\sigma^{\dagger}} \leq \sum_{\sigma^{\dagger}=1}^{d} (2\omega - 2\bm{y}_{\sigma^{\dagger}}^{\top} (\omega \bm{I} - \bm{C}) \bm{q}_{\sigma^{\dagger}} - \bm{q}_{\sigma^{\dagger}}^{\top} \bm{C} \bm{q}_{\sigma^{\dagger}}).
$$
 (25)

Here,  $d = k - 1$ . For the left-hand side of Eq. [\(25\)](#page-7-0), the matrix notation can be described as  $tr(Y^{\top}CY)$  =  $\sum_{\sigma^\dagger=1}^d \bm{y}_{\sigma^\dagger}^\top \bm{C} \bm{y}_{\sigma^\dagger}.$  With use Eq. [\(25\)](#page-7-0), it can be expressed as

$$
\sum_{\sigma^\dagger=1}^d \bm{y}_{\sigma^\dagger}^\top \bm{C} \bm{y}_{\sigma^\dagger} \leq \sum_{\sigma^\dagger=1}^d (2\omega-2\bm{y}_{\sigma^\dagger}^\top(\omega \bm{I}-\bm{C})\bm{q}_{\sigma^\dagger}-\bm{q}_{\sigma^\dagger}^\top \bm{C}\bm{q}_{\sigma^\dagger}) \\ \iff \quad \text{tr}(\bm{Y}^\top \bm{C} \bm{Y}) \leq 2\omega-2\text{tr}(\bm{Y}^\top(\omega \bm{I}-\bm{C})\bm{Q}-\text{tr}(\bm{Q}^\top \bm{C}\bm{Q}),
$$

where  $\boldsymbol{Y}^\top \boldsymbol{Y} = \boldsymbol{Q}^\top \boldsymbol{Q} = \boldsymbol{I}.$ 

Lemma 2. The following inequality is satisfied:

$$
\frac{1}{2} \|\mathbf{Y} - \mathbf{H}_n \mathbf{X} \mathbf{B}\|_F^2 + \sum_{l \in \varepsilon} \boldsymbol{\lambda}_l^\top (\mathbf{v}_l^\dagger - \mathbf{y}_i + \mathbf{y}_j) + \frac{\rho}{2} \sum_{l \in \varepsilon} \|\mathbf{v}_l^\dagger - \mathbf{y}_i + \mathbf{y}_j\|_2^2
$$
\n
$$
\leq - \operatorname{tr} \mathbf{Y}^\top \left( \mathbf{X}^\dagger + \sum_{l \in \varepsilon} g_l \boldsymbol{\lambda}_l^\top + \rho \sum_{l \in \varepsilon} g_l \mathbf{v}_l^\dagger + 2(\omega \mathbf{I} - \mathbf{C}) \mathbf{Q} \right) + \text{const},
$$
\n(26)

where const is terms not relevant to  $Y$ .

*Proof.* From Eq. [\(24\)](#page-6-4) in Lemma [1](#page-6-5), the majorizing function of Eq. [\(23\)](#page-6-3) can be derived as follows:

$$
\frac{1}{2} \|\mathbf{Y} - \mathbf{X}^{\dagger}\|_{F}^{2} + \sum_{l \in \varepsilon} \boldsymbol{\lambda}_{l}^{\top} (\mathbf{v}_{l}^{\dagger} - \mathbf{Y}^{\top} \mathbf{g}_{l}) + \frac{\rho}{2} \sum_{l \in \varepsilon} \|\mathbf{v}_{l}^{\dagger} - \mathbf{Y}^{\top} \mathbf{g}_{l}\|_{2}^{2}
$$
\n(27)

$$
= -\operatorname{tr} \mathbf{Y}^{\top} \left( \mathbf{X}^{\dagger} + \sum_{l \in \varepsilon} g_l \boldsymbol{\lambda}_l^{\top} + \rho \sum_{l \in \varepsilon} g_l \boldsymbol{v}_l^{\dagger \top} \right) + \frac{\rho}{2} \operatorname{tr} \left( \mathbf{Y}^{\top} \sum_{l \in \varepsilon} g_l \boldsymbol{g}_l^{\top} \mathbf{Y} \right)
$$
(28)

$$
\leq -\operatorname{tr} \boldsymbol{Y}^{\top} \left( \boldsymbol{X}^{\dagger} + \sum_{l \in \varepsilon} g_l \boldsymbol{\lambda}_l^{\top} + \rho \sum_{l \in \varepsilon} g_l \boldsymbol{v}_l^{\dagger \top} \right) + 2\omega - 2 \operatorname{tr} (\boldsymbol{Y}^{\top} (\omega \boldsymbol{I} - \boldsymbol{C}) \boldsymbol{Q}) - \operatorname{tr} (\boldsymbol{Q}^{\top} \boldsymbol{C} \boldsymbol{Q}) \tag{29}
$$

$$
= -\operatorname{tr} Y^{\top} \Big( X^{\dagger} + \sum_{l \in \varepsilon} g_l \lambda_l^{\top} + \rho \sum_{l \in \varepsilon} g_l v_l^{\dagger \top} \Big) - 2 \operatorname{tr} (Y^{\top} (\omega I - C) Q) + \text{const}
$$
  

$$
= -\operatorname{tr} Y^{\top} \Big( X^{\dagger} + \sum_{l \in \varepsilon} g_l \lambda_l^{\top} + \rho \sum_{l \in \varepsilon} g_l v_l^{\dagger \top} + 2(\omega I - C) Q \Big) + \text{const.}
$$
(30)

From Eq.  $(27)$  to Eq.  $(28)$ , the transformation from Eq.  $(21)$  to Eq.  $(23)$  is used. Next, in Eq.  $(28)$  to Eq.  $(29)$ , the right-hand side of Eq. [\(24\)](#page-6-4) derived by the majorizing function was applied to the second term of Eq. [\(28\)](#page-7-2). Then, Eq. [\(30\)](#page-7-4) can be explained as linear term of  $Y$ .

<span id="page-7-6"></span><span id="page-7-4"></span><span id="page-7-3"></span><span id="page-7-2"></span> $\Box$ 

The left-hand side of Eq. [\(26\)](#page-7-5) are terms related to  $Y$  from Eq. [\(11\)](#page-3-5).

**Definition 1.** Eq. [\(30\)](#page-7-4) is defined as the majorizing function for the objective function:

$$
M(\boldsymbol{Y}|Q) = -\mathrm{tr}\boldsymbol{Y}^{\top}\left(\boldsymbol{X}^{\dagger} + \sum_{l \in \varepsilon} g_l \boldsymbol{\lambda}_l^{\top} + \rho \sum_{l \in \varepsilon} g_l \boldsymbol{v}_l^{\dagger \top} + 2(\omega \boldsymbol{I} - \boldsymbol{C})\boldsymbol{Q}\right) + \text{const.}
$$
 (31)

When  $Q = Y$ , Eq. [\(31\)](#page-7-6) is equal to the function of Eq. [\(11\)](#page-3-5). Proposition [2](#page-8-1) states that the problem of minimizing Eq. [\(11\)](#page-3-5) can be expressed in Eq. [\(19\)](#page-5-4).

<span id="page-7-5"></span><span id="page-7-1"></span><span id="page-7-0"></span> $\Box$ 

<span id="page-8-1"></span>**Proposition 2.** Given  $X^\dagger, g_l, \lambda_l, v_l^\dagger, C, Q,$  and  $\omega$ , the minimization problem of the majorizing function  $M(Y|Q)$  is equivalent to solving the orthogonal procrustes problem for Eq. [\(19\)](#page-5-4).

$$
\|\boldsymbol{Y}-\boldsymbol{D}\|_F^2\to\min
$$

s.t.  $\boldsymbol{Y}^\top \boldsymbol{Y} = \boldsymbol{I},$ 

where

$$
\boldsymbol{D} = \frac{1}{2}\bigg(\boldsymbol{X}^{\dagger} + \sum_{l\in\varepsilon}\boldsymbol{g}_l\boldsymbol{\lambda}_l^{\top} + \rho\sum_{l\in\varepsilon}\boldsymbol{g}_l\boldsymbol{v}_l^{\dagger\top} + 2(\omega\boldsymbol{I}-\boldsymbol{C})\boldsymbol{Q}\bigg).
$$

*Proof.* From Eq. [\(20\)](#page-6-0) and the constraint  $Y^{\top}Y = I$ ,

$$
\|\mathbf{Y} - \mathbf{D}\|_{F}^{2} = \text{tr}(\mathbf{Y}^{\top}\mathbf{Y}) - 2\text{tr}(\mathbf{Y}^{\top}\mathbf{D}) + \text{const} = (k - 1) - 2\text{tr}(\mathbf{Y}^{\top}\mathbf{D}) + \text{const.}
$$
 (32)

Since the first term is a constant value due to the constraints, the minimization problem in Eq. [\(32\)](#page-8-2) is the same as the maximization problem of  $2tr(Y^{\top}D)$  in Eq. [\(32\)](#page-8-2). Therefore, the minimization problem of Eq. (32) is equivalent to the maximization problem of  $M(Y|Q)$ .  $\Box$ 

# <span id="page-8-0"></span>3.5 Update  $Y^{\dagger}$

In this subsection, the updated formulas for  $Y$ ,  $V^{\dagger}$ , and  $\Lambda$  in  $Y^{\dagger}$  by using ADMM algorithm are described.

# Update Y

The updated formula of  $Y$  in ADMM algorithm is shown in [3.4](#page-5-0) as

<span id="page-8-3"></span><span id="page-8-2"></span>
$$
\boldsymbol{Y} \leftarrow \boldsymbol{L} \boldsymbol{R}^\top,
$$

where  $L$  and  $R$  come from the singular value decomposition from  $D$  as the following:

$$
\boldsymbol{D} = \frac{1}{2} \bigg( \boldsymbol{X}^{\dagger} + \sum_{l \in \varepsilon} \boldsymbol{g}_l \boldsymbol{\lambda}_l^{\top} + \rho \sum_{l \in \varepsilon} \boldsymbol{g}_l \boldsymbol{v}_l^{\dagger \top} + 2(\omega \boldsymbol{I} - \boldsymbol{C}) \boldsymbol{Q} \bigg) = \boldsymbol{L} \boldsymbol{\Sigma} \boldsymbol{R}^{\top}
$$

from Proposition [2](#page-8-1).

Update  $V^\dagger$ 

**Proposition 3.** Given  $s_l, \psi_l$  ( $\psi_l > 0$ ), the updated formula of  $\boldsymbol{v}_l^{\dagger}$  is

$$
\boldsymbol{v}_l^{\dagger} \leftarrow \begin{cases} \boldsymbol{s}_l \Big( 1 - \frac{\psi_l}{\|\boldsymbol{s}_l\|_2} \Big), & (\|\boldsymbol{s}_l\|_2 > \psi_l) \\ \boldsymbol{0}, & (\|\boldsymbol{s}_l\|_2 \leq \psi_l) \end{cases} \tag{33}
$$

where  $s_l = v_l^{\dagger} - (\psi_l(v_l - q_l)), q_l = y_i - y_j - \rho^{-1} \lambda_l$ , and  $\psi_l = \frac{\gamma \alpha_l}{\rho}$ .

*Proof.* The updated formula of  $V^{\dagger}$  can be solved as the same manner of [Chi and Lange](#page-19-16) [\[2015\]](#page-19-16). It is derived by the proximal gradient method. First, for a certain l in the terms related to  $V^{\dagger}$  in Eq. [\(11\)](#page-3-5),

$$
\boldsymbol{\lambda}^{\top}_l (\boldsymbol{v}^{\dagger}_l - \boldsymbol{y}_i + \boldsymbol{y}_j) + \frac{\rho}{2} \|\boldsymbol{v}^{\dagger}_l - \boldsymbol{y}_i + \boldsymbol{y}_j\|_2^2 + \gamma \alpha_l \|\boldsymbol{v}^{\dagger}_l\|_2
$$

First, multiply  $\rho^{-1}$  to Eq. [\(11\)](#page-3-5).

$$
\rho^{-1}\boldsymbol{\lambda}_l^\top(\boldsymbol{v}_l^\dagger-\boldsymbol{y}_i+\boldsymbol{y}_j)+\frac{1}{2}\|\boldsymbol{v}_l^\dagger-\boldsymbol{y}_i+\boldsymbol{y}_j\|_2^2+\frac{\gamma\alpha_l}{\rho}\|\boldsymbol{v}_l^\dagger\|_2\\=\frac{1}{2}\big((\boldsymbol{v}_l^\dagger-\boldsymbol{y}_i+\boldsymbol{y}_j)^\top(\boldsymbol{v}_l^\dagger-\boldsymbol{y}_i+\boldsymbol{y}_j)\big)+\rho^{-1}\boldsymbol{\lambda}^T(\boldsymbol{v}_l^\dagger-\boldsymbol{y}_i+\boldsymbol{y}_j)+\frac{\gamma\alpha_l}{\rho}\|\boldsymbol{v}_l^\dagger\|_2\\=\frac{1}{2}\bigg(\big((\boldsymbol{v}_l^\dagger-\boldsymbol{y}_i+\boldsymbol{y}_j)+\rho^{-1}\boldsymbol{\lambda}_l\big)^\top\big((\boldsymbol{v}_l^\dagger-\boldsymbol{y}_i+\boldsymbol{y}_j)+\rho^{-1}\boldsymbol{\lambda}_l\big)\bigg)-\frac{1}{2}\|\rho^{-1}\boldsymbol{\lambda}_l\|_2^2+\frac{\gamma\alpha_l}{\rho}\|\boldsymbol{v}_l^\dagger\|_2
$$

As for the terms related to  $v_l^{\dagger}$ :

$$
\begin{aligned} &\frac{1}{2}\biggl(\bigl((\boldsymbol{v}_l^{\dagger}-(\boldsymbol{y}_i-\boldsymbol{y}_j-\rho^{-1}\boldsymbol{\lambda}_l)^\top\bigl((\boldsymbol{v}_l^{\dagger}-(\boldsymbol{y}_i-\boldsymbol{y}_j-\rho^{-1}\boldsymbol{\lambda}_l)\bigr)\biggr)+\frac{\gamma\alpha_l}{\rho}\|\boldsymbol{v}_l^{\dagger}\|_2\\ =&\frac{1}{2}\|\boldsymbol{v}_l^{\dagger}-(\boldsymbol{y}_i-\boldsymbol{y}_j-\rho^{-1}\boldsymbol{\lambda}_l)\|_2^2+\frac{\gamma\alpha_l}{\rho}\|\boldsymbol{v}_l^{\dagger}\|_2.\end{aligned}
$$

Therefore, the derivation of the updated formula for  $v_l^{\dagger}$  can be obtained by solving the following minimization problem.

$$
\underset{\boldsymbol{v}_l^{\dagger}}{\operatorname{argmin}} \frac{1}{2} \|\boldsymbol{v}_l - (\boldsymbol{y}_i - \boldsymbol{y}_j - \rho^{-1}\boldsymbol{\lambda}_l)\|_2^2 + \frac{\gamma \alpha_l}{\rho} \|\boldsymbol{v}_l^{\dagger}\|_2.
$$
 (34)

Then, Eq. [\(34\)](#page-9-0) is divided into the differentiable terms and the other terms, similar to the case of updated formula of B in Eq. [\(16\)](#page-5-5).

$$
\begin{cases}\nf^{\dagger}(\boldsymbol{v}_l^{\dagger}) = \frac{1}{2} \|\boldsymbol{v}_l^{\dagger} - (\boldsymbol{y}_i - \boldsymbol{y}_j - \rho^{-1}\boldsymbol{\lambda}_l)\|_2^2 \\
g^{\dagger}(\boldsymbol{v}_l^{\dagger}) = \frac{\gamma \alpha_l}{\rho} \|\boldsymbol{v}_l^{\dagger}\|_2\n\end{cases}
$$

The gradient for  $f^{\dagger}(\mathbf{v}_l^{\dagger})$  is calculated as follows and set as  $s_l$ :

<span id="page-9-1"></span><span id="page-9-0"></span>
$$
s_l \equiv \boldsymbol{v}_l^{\dagger} - \psi_l(\boldsymbol{v}_l^{\dagger} - \boldsymbol{q}_l).
$$

From this, the proximal operator of  $g^{\dagger}(\boldsymbol{s}_l)$  can be derived as

$$
\mathbf{prox}_{\psi_l g^\dagger}(\boldsymbol{s}_l) = \operatorname{argmin}\left(\psi_l \|\boldsymbol{v}_l^\dagger\|_2 + \frac{1}{2} \|\boldsymbol{v}_l^\dagger - \boldsymbol{s}_l\|_2^2\right).
$$
 (35)

Similar to Eq. [\(18\)](#page-5-3), when  $\psi_l \neq 0$ , Eq. [\(35\)](#page-9-1) can be obtained from differentiating by  $v_l^{\dagger}$ , and is assumed as 0.

$$
\mathbf{v}_{l}^{\dagger} - \mathbf{s}_{l} + \psi_{l} \frac{\mathbf{v}_{l}^{\dagger}}{\|\mathbf{v}_{l}^{\dagger}\|_{2}} = \mathbf{0}
$$
\n
$$
\Leftrightarrow \qquad \mathbf{v}_{l}^{\dagger} \left(1 + \psi_{l} \frac{1}{\|\mathbf{v}_{l}^{\dagger}\|_{2}}\right) = \mathbf{s}_{l} \qquad (i^{\dagger})
$$
\n
$$
\Leftrightarrow \qquad \left(1 + \psi_{l} \frac{1}{\|\mathbf{v}_{l}^{\dagger}\|_{2}}\right)^{\top} \mathbf{v}_{l}^{\dagger \top} \mathbf{v}_{l}^{\dagger} \left(1 + \psi_{l} \frac{1}{\|\mathbf{v}_{l}^{\dagger}\|_{2}}\right) = \mathbf{s}_{l}^{\top} \mathbf{s}_{l} \qquad (i^{\dagger})
$$
\n
$$
\Leftrightarrow \qquad \left(1 + \psi_{l} \frac{1}{\|\mathbf{v}_{l}^{\dagger}\|_{2}}\right)^{2} \|\mathbf{v}_{l}^{\dagger}\|_{2}^{2} = \|\mathbf{s}_{l}\|_{2}^{2}
$$
\n
$$
\Leftrightarrow \qquad \left(1 + \psi_{l} \frac{1}{\|\mathbf{v}_{l}^{\dagger}\|_{2}}\right) \|\mathbf{v}_{l}^{\dagger}\|_{2} = \|\mathbf{s}_{l}\|_{2}
$$

Substitute Eq.  $(ii^{\dagger})$  into Eq.  $(i^{\dagger})$ .

$$
\begin{aligned}\n\boldsymbol{v}_l^\dagger \bigg( 1 + \psi_l \frac{1}{\|\boldsymbol{s}_l\|_2 - \psi_l} \bigg) &= & \boldsymbol{s}_l \\
&\Longleftrightarrow \boldsymbol{v}_l^\dagger \bigg( \frac{\|\boldsymbol{s}_l\|_2 - \psi_l + \psi_l}{\|\boldsymbol{s}_l\|_2 - \psi_l} \bigg) &= & \boldsymbol{s}_l \\
&\Longleftrightarrow \boldsymbol{v}_l^\dagger \left( 1 - \frac{\psi_l}{\|\boldsymbol{s}_l\|_2} \right)\n\end{aligned}
$$

# Update Λ

The updated formula of  $\Lambda$  is based on ADMM, and it is updated by each l, which is defined as follows:

$$
\boldsymbol{\lambda}_l \leftarrow \boldsymbol{\lambda}_l + \rho(\boldsymbol{v}_l^{\dagger} - \boldsymbol{y}_i + \boldsymbol{y}_j).
$$

The detail of the algorithm is shown in Algorithm1.

 $\Box$

# 4 Numerical Simulation

# 4.1 Simulation design

We implemented the proposed method to assess its performance. First, we explain the design of numerical simulation. The settings are based on modified ones of [Wang et al.](#page-19-4) [\[2016\]](#page-19-4). The data matrix  $X \in \mathbb{R}^{n \times p}$  is generated containing true clustering structure. The number of subjects n is 60 and the number of covariates p is 20 and 50. The number of clusters  $k$  is 3 and 4. The evaluation index is Adjusted Rand Index (ARI) [\[Hubert and Arabie, 1985\]](#page-20-0) between estimated clustering structure and true clustering structure.

Covariates corresponding to cluster  $\ell$  is generated from  $\mathbf{X}_{\ell} \sim N(\boldsymbol{\mu}_{\ell}, \tilde{\boldsymbol{\Sigma}})$   $(\ell = 1, 2, \cdots, k)$ , where  $\boldsymbol{\mu}_{\ell} \in \mathbb{R}^p$  is mean vector of cluster  $\ell$ , and

$$
\tilde{\mathbf{\Sigma}} = \left(\begin{array}{cccc} \mathbf{\Sigma}^{\S} & \mathbf{O}_{q,c^*} & \mathbf{O}_{q,(p-q-c^*)} \\ \mathbf{O}_{c^*,q} & \mathbf{\Sigma}^{\ddagger} & \mathbf{O}_{c^*,(p-q-c^*)} \\ \mathbf{O}_{(p-q-c^*),q} & \mathbf{O}_{(p-q-c^*) , c^*} & \mathbf{I}_{(p-q-c^*)} \end{array}\right).
$$

 $\tilde{\Sigma}$  is the covariance matrix and  $I_{(p-q-c^*)}$  is identity matrix. X contains the informative variable from the first to qth, where q is the number of informative covariates. q is set as 2 for  $p = 20$  and 6 for  $p = 50$ . First,  $\Sigma^{\S}$  is the covariance within informative variables, which include true clustering structure. It is set as

$$
\Sigma^{\S} = (1 - \xi) \mathbf{I}_q + \xi \mathbf{1}_q \mathbf{1}_q^{\top} \in \mathbb{R}^{q \times q},
$$

where  $\xi$  is variance of informative covariates, whose settings will be denoted in Factor 5.  $I_q$  is identity matrix and  $\mathbf{1}_q = (1, 1, \cdots, 1)^\top$  is a vector of 1.

Next, for the remaining of the variable, non-informative covariates  $(p - q)$ , we set two different parts: non-informative covariate variables including higher correlation and those with no correlation. For non-informative covariates including higher correlations, we set as follows:

$$
\Sigma^{\ddagger} = (1 - \xi^{\dagger}) \mathbf{I}_{c^*} + \xi^{\dagger} \mathbf{1}_{c^*} \mathbf{1}_{c^*}^{\top} \in \mathbb{R}^{c^* \times c^*}.
$$

Here,  $\xi^{\dagger} = 0.6$ . This corresponds to  $(q+1)$  th to  $(q + c^*)$ th variables in **X**.  $c^*$  is the number of non-informative covariates with higher correlation.  $c^*$  is set 12 for  $p = 20$ , and 24 for  $p = 50$ .  $I_{c^*}$  is identity matrix and  $\mathbf{1}_{c^*}$  is vector of 1. The rest from  $(q + c^* + 1)$ th to pth non-informative covariate variables is generated from standard normal distribution. Next, mean vectors of each cluster  $\mu_{\ell} = (m_{\ell}^{\top}, 0^{\top})$  are determined as follows:

$$
\begin{aligned} & \boldsymbol{m}_1 = \!\vartheta\,!-\!\mathbf{1}_{q/2}^\top, \mathbf{1}_{q/2}^\top)^\top, \\ & \boldsymbol{m}_2 = \!\vartheta\mathbf{1}_q, \\ & \boldsymbol{m}_3 = \!\vartheta\!\left(\mathbf{1}_{q/2}^\top, -\mathbf{1}_{q/2}^\top\right)^\top, \text{ and} \\ & \boldsymbol{m}_4 = \!\vartheta\!\left(-\mathbf{1}_q\right), \end{aligned}
$$

where  $\vartheta$  is a parameter to set the location of the cluster mean, which will be indicated in Factor 4.

The number of total patterns is 4 (Factor 1)  $\times$  2 (Factor 2)  $\times$  2 (Factor 3)  $\times$  3 (Factor 4)  $\times$  2 (Factor 5) = 96. We randomly generate data and repeat the calculation 100 times for each 24 patterns. As for evaluation index, Adjusted Rand Index (ARI) between estimated clustering structure and true clustering structure is used to assess how well they match the true clusters. For the proposed method and SODC, the ARI was calculated from  $H_n X \hat{B}$ , where  $\hat{B}$  indicates estimated  $B$ . For calculating ARI, mclust package in R software [\[Scrucca et al., 2023\]](#page-20-1) is used.

# Factor 1: Methods

We compare four methods, and three compared methods are applied: sparse optimal discriminant clustering (SODC) [\[Wang et al., 2016\]](#page-19-4), tandem clustering [\[Arabie and Hubert, 1994\]](#page-20-2) in  $(k - 1)$  dimension, and reduced k-means [\[Chen](#page-20-3) [and Huang, 2012\]](#page-20-3) in  $(k - 1)$  dimension. We use Eq. [\(2\)](#page-2-0) for SODC. In this setting, we set  $\eta_2 = 0$  in the proposed method and SODC.

For reduced k-means, we use clustrd package in R software [\[Markos et al., 2019\]](#page-20-4). For tuning parameters  $\eta_1$ ,  $\gamma$  and  $\rho$  in the proposed method are selected by modified cross-validation based on the idea of clustering stability [\[Wang et al.,](#page-19-4) [2016,](#page-19-4) [Sun et al., 2013\]](#page-19-18) which is based on kappa coefficient [\[Cohen, 1960\]](#page-19-17). For weight of the penalty term for  $Y$ , we adapted  $\psi^* = 0.1$  and  $m^* = 25$ . For SODC,  $\eta_1$  is selected in the same manner.

# Factor 2: Covariate variable

The number of covariate variable is set as  $p = 20$  and 50.

# Factor 3: Number of cluster

The number of cluster is  $k = 3$  and 4.

# Factor 4: Parameter  $\vartheta$  for informative covariate variable

 $\vartheta$  is distance between cluster centroids.  $\vartheta$  is set as 1.4, 2.0, and 2.2.

#### Factor 5: Parameter  $\xi$  for informative covariate variable

 $\xi$  is variance of informative covariate variables, and set as  $\xi = 0$  and 0.5.

# 4.2 Simulation results

The simulation results for each number of clusters k and covariate variables are shown in Figure [1](#page-12-0) to Figure [4.](#page-15-0) The results for  $k = 3$  and  $p = 20$  are shown in Figure [1,](#page-12-0)  $k = 3$  and  $p = 50$  in Figure [2,](#page-13-0)  $k = 4$  and  $p = 20$  in Figure [3,](#page-14-0) and  $k = 4$  and  $p = 50$  in Figure [4.](#page-15-0) The proposed method demonstrated better ARI results for almost all patterns than all compared methods.

Figure [1](#page-12-0) shows the results for  $k = 3$  and  $p = 20$ . The proposed method outperformed all comparative methods at most patterns in  $p = 20$ . For  $\vartheta$ , the distance between cluster centroids, ARI values increased as  $\vartheta$  became larger for all methods except reduced k-means. This trend was noticeable in the proposed method. As the value of  $\xi$  increased, the value of ARI increased in almost all patterns for the methods except reduced k-means. In particular, as  $\vartheta$  increased, the proposed method had better ARI values for  $\xi = 0.5$  than for  $\xi = 0$ .

Figure [2](#page-13-0) shows the results in  $k = 3$  and  $p = 50$ . The proposed method was superior to all compared methods in all patterns. The median value of SODC was almost the same as that of the proposed method at  $\vartheta = 1.4$  and  $\xi = 0.5$ . With regard to  $\vartheta$ , there was a tendency for the value of ARI to increase for all patterns as the value of  $\vartheta$  increased. This trend was the same for  $p = 20$  and was more pronounced for the proposed method. On the other hand, in SODC, ARI decreased when  $\vartheta = 2$  and the ARI for reduced k-means remained unchanged and lower regardless of the value of  $\vartheta$ . For  $\xi$ , the ARIs of the proposed method, SODC, and tandem clustering have increased with larger  $\xi$  at  $\vartheta = 2$  and 2.2.

Next, the results for  $k = 4$  are presented. The results of  $k = 4$  and  $p = 20$  are shown in Figure [3.](#page-14-0) The proposed method performed better than the other compared methods for all patterns; SODC performed better followed by the proposed method. First, observing the results for each  $\vartheta$ , the value of ARI has increased as the value of  $\vartheta$  increases for almost all methods. While this is the same trend as for  $k = 3$ , the degree of increasing for the proposed method was greater for

<span id="page-12-0"></span>Figure 1: Results of ARI in  $k = 3$ ,  $p = 20$  by parameter  $\vartheta$  and  $\xi$ . The vertical axis describes ARI.

<span id="page-13-0"></span>Figure 2: Results of ARI in  $k = 3$ ,  $p = 50$ . The vertical axis describes ARI.

<span id="page-14-0"></span>Figure 3: Results of ARI in  $k = 4$ ,  $p = 20$ . The vertical axis describes ARI.

<span id="page-15-0"></span>Figure 4: Results of ARI in  $k = 4$ ,  $p = 50$ . The vertical axis describes ARI.

<span id="page-16-0"></span>Table 1: Results of ARI. tandem indicates tandem clustering, and RKM indicates reduced  $k$ -means.

 $k = 4$ . In  $\xi$ , the change was less than for the case of  $k = 3$  and  $p = 20$ .

The results of  $k = 4$  and  $p = 50$  are shown in Figure [4.](#page-15-0) The proposed method outperformed the compared methods for all patterns. For  $\vartheta = 2.2$  and  $\xi = 0$ , the median ARI of the methods except reduced k-means was 1, while the range of ARI results for the proposed method was almost 1. For all methods, the higher value of  $\vartheta$ , the better ARI value, and a similar trend was observed for  $k = 3$ . On the other hand, unlike the case of  $k = 3$ , the overall results at  $\xi = 0$  provided better than the case at  $\xi = 0.5$ .

# 5 Real data application

### 5.1 Data description

We present the genetic real data application to the proposed method. Dataset "srbct" [\[Kahn et al., 2001\]](#page-20-5) from R package mixOmics [\[Rohart et al., 2017\]](#page-20-6) contains expression measure of 2308 genes in subject 63 associated with small, round blue-cell tumors (SRBCTs). The data are based on the diagnosis of four types of cancer; neuroblastoma (NB), rhabdomyosarcoma (RMS), Birkitt lymphomas (BL; a subset of non-Hodgkin lymphoma) and the Ewing family of tumours (EWS), by using artificial neural networks. For this data application, BL and RMS were selected from the class and 50 variables were picked up, with 5 informative variables corresponding to higher F-values in sequence and 45 variables corresponding to lower F-values. The F-value is calculated from the variance ratio of the analysis of variance (ANOVA); a higher F-value indicates greater variance between each class, which means a greater ability to identify class structure. On the other hand, when F-value is lower, it does not contribute to class structure much. Therefore, we treat them as non-informative variable.

The evaluation indices are Adjusted Rand Index (ARI) between estimated clustering structure and true clustering structure, variance ratio in estimated  $B$  and  $Y$ , and the sensitivity and the specificity of  $B$ . The variance ratio is calculated by ratio between the variance within cluster and that between each cluster. A higher variance ratio signifies that the clusters are more identified. Then, we explain the evaluation on sensitivity and specificity of B. The ideal situation is that the informative to be non-sparse and the non-informative to be sparse. The sensitivity and specificity are defined as follows:

Sensitivity = 
$$
\frac{\text{the number of nonzero elements corresponding to informative variables}}{5 \times (k-1)},
$$

 $Specificity = \frac{\text{the number of zero elements corresponding to noninformative variables}}{45 \times (k-1)}$ .

If the value of sensitivity is high, it means that informative variables are estimated as non-zero and the required information is correctly captured. A high value of specificity indicates that unnecessary information is estimated as zero and that the information is correctly dropped.

The parameters of  $\eta_1$ ,  $\gamma$ , and  $\rho$  were determined by cross-validation on kappa statistics [\[Wang et al., 2016,](#page-19-4) [Sun et al.,](#page-19-18) [2013\]](#page-19-18). As for compared methods, three methods were applied for ARI as in the numerical simulation: SODC, tandem clustering [\[Arabie and Hubert, 1994\]](#page-20-2), and reduced k-means [\[Soete and Carroll, 1994\]](#page-19-0) in  $(k - 1)$  dimension. For variance ratio and the sensitivity and specificity, we compared the proposed method with SODC.

# 5.2 Results of data application

The results of ARI are shown in Table [1.](#page-16-0) The ARI value for the proposed method was higher than that of the compared methods. Next, we show the results of the variance ratio in  $\overrightarrow{XB}$  and  $\overrightarrow{Y}$  and those plots, where  $\overrightarrow{B}$  and  $\overrightarrow{Y}$  indicate estimated  $B$  and  $Y$ , respectively. We compared the variance ratio of the proposed method and SODC with respect to  $\hat{X}\hat{B}$  and  $\hat{Y}$  in Table [2.](#page-17-0) The values of variance ratio in the proposed method was larger than those of SODC for both  $\hat{X}\hat{B}$  and  $\hat{Y}$ . We plot these estimated parameters in Figure [5](#page-17-1) and in Figure [6.](#page-18-0)  $\hat{X}\hat{B}$  applied to k-means in the proposed method and SODC is plotted in Figure [5.](#page-17-1) The vertical axis is  $\overrightarrow{XB}$ , and the horizontal axis is subject index. The color of the data points represents estimated cluster, while the shape represents the true cluster. Figure [5](#page-17-1) shows that

<span id="page-17-0"></span>Figure 5: Result of  $\overrightarrow{XB}$  in the proposed method and SODC. The vertical axis is  $\overrightarrow{XB}$  and the horizontal axis is index. The color of the point shows cluster estimated by the methods, and the shape of the point indicates the true cluster.

<span id="page-17-1"></span>

the proposed method classified the clusters into two clusters and was almost identical to the true clustering structure. The results of estimated  $Y$  in the proposed method and SODC are shown in Figure [6.](#page-18-0) The color and the shape of the plots indicates the estimated cluster and the true cluster, respectively. For the proposed method, the two clusters were separated almost similarly to the true clusters on the left of Figure [5,](#page-17-1) and SODC was also consistent with the proposed method. The proposed method seemed to plot the points in the same cluster closer together. At the two misclassified points, the proposed method showed plots that were slightly closer to true clusters than SODC.

Finally, in Table [3,](#page-17-2) the results show the sensitivity and the specificity of  $\bf{B}$  in the proposed method and SODC. The proposed method could estimate the informative variables as relatively non-sparse, while SODC estimated those variables as 0. It indicates that the proposed method could detect the informative variable properly. On the other hand, SODC estimated non-informative variables as almost 0, whereas the proposed method estimated some variables as non-zero.

<span id="page-17-2"></span>Table 3: Results of sensitivity and specificity of the proposed method and SODC.

<span id="page-18-0"></span>Figure 6: Result of  $\hat{Y}$  of the proposed method and SODC. The vertical axis is  $\hat{Y}$  and the horizontal axis is index. The color of the point shows cluster estimated by the methods, and the shape of the point indicates the true cluster.

# 6 Discussion and Conclusion

In this study, we proposed a novel SODC method with the penalty term from convex clustering to scoring matrix Y. With adding this penalty term, the proposed method was allowed to capture the clustering structure more clearly compared to SODC. It found that the proposed method have captured the same cluster points closer and the different points further compared to SODC by the results of variance ratio in real data application. Throughout the numerical simulations, it found that the performance of clustering identification was also compared favorably with other dimension reduction clustering methods in this setting. We also developed an algorithm by using the majorizing function to derive the updated formula of  $Y$ . This enabled satisfying the orthogonal constraint for  $Y$  and containing the clustering structure simultaneously. The proposed method used orthogonal Procrustes analysis for updating  $Y$ . However, the terms related to Y consisted of both quadratic and linear forms, although it must be expressed in only linear form. Consequently, we derived a majorizing function to ensure that it could be represented exclusively in linear form.

The results of numerical simulation are discussed in detail. From the numerical simulation, the proposed method performed better overall in the setting in this study than the compared method. It shows that the proposed method was effective in capturing the clustering structures and maintaining the estimation accuracy when the number of true clustering structure was small. The proposed method obtained more stable results compared to SODC by assuming that there is a cluster structure and adding a regularization term to  $Y^{\dagger}$ . However, since the Ridge term was calculated as 0 in this study, it is considered that the addition of a Ridge penalty term [\[Hoerl and Kennard, 1970\]](#page-20-7) may improve the stability of the accuracy of the estimation in the proposed method and in SODC.

In real data application, the ARI value showed that the proposed method captured the clustering structure more accurately than the compared method. From the variance ratio, the proposed method was found to improve the estimation of different clusters further apart and the same clusters closer together compared to SODC. That seems to be confirmed by Figure [5](#page-17-1) and Figure [6.](#page-18-0) Regarding the estimation of  $B$ , the proposed method estimated the informative variables as non-zero more than SODC. On the other hand, SODC estimated estimate sparse for non-informative variables more than the proposed method.

Meanwhile, there are some considerations that should be considered to enhance the proposed method. First, crossvalidation for parameter  $\eta_1$ ,  $\gamma$  and  $\rho$  was performed based on the idea of clustering stability, as in the selection method of conventional SODC [\[Wang et al., 2016,](#page-19-4) [Sun et al., 2013\]](#page-19-18), however, this method is computationally expensive. In order to reduce computational cost, consideration should be given to accelerating the calculation and deriving an information criterion. In addition, in this cross-validation, parameters were explored using kappa coefficients based on the idea of stability of variable selection, but it is necessary to consider implementing cross-validation based on the stability of clustering results. Finally, in this study, k-means was applied to the calculation of clustering results in this study, as k-means has been applied to SODC among various methods. Comparing the calculation results with other clustering methods needs to be considered.
