#### **Abstract**

Despite the increasing importance of stochastic processes on linear networks and graphs, current literature on multivariate (vectorvalued) Gaussian random fields on metric graphs is elusive. This paper challenges several aspects related to the construction of proper matrixvalued kernels structures. We start by considering matrix-valued metrics that can be composed with scalar- or matrix-valued functions to implement valid kernels associated with vector-valued Gaussian fields. We then provide conditions for certain classes of matrix-valued functions to be composed with the univariate resistance metric and ensure positive semidefiniteness. Special attention is then devoted to Euclidean trees, where a substantial effort is required given the absence of literature related to multivariate kernels depending on the *ℓ*<sup>1</sup> metric. Hence, we provide a foundational contribution to certain classes of matrix-valued positive semidefinite functions depending on the  $\ell_1$  metric. This fact is then used to characterise kernels on Euclidean trees

with a finite number of leaves. Amongst those, we provide classes of matrix-valued covariance functions that are compactly supported.

### **1 Introduction**

### **1.1 Context: Random Fields on Networks**

Networks analysis has become ubiquitous in several branches of theoretical and applied sciences, including mathematics, statistics, machine learning, artificial intelligence, with applications connected to the data planet. Networks can be used, either, to represent connections between random variables, or to provide a topological structure where a given process (called a random field) is observed. Our paper deals with the second situation, under the condition that the observed process is a vector-valued Gaussian random field that is second-order isotropic in the sense that the matrix-valued covariance kernel depends on distance between the points in the network.

Random fields can be continuously [\[Anderes et al.,](#page-27-0) [2020\]](#page-27-0) or discretely indexed over a network; for the second case, the common nomenclature is that of point processes on networks [\[Moradi and Mateu,](#page-27-1) [2020,](#page-27-1) [Baddeley et al.,](#page-27-2) [2021,](#page-27-2) [Rakshit et al.,](#page-27-3) [2017\]](#page-27-3). For both cases, defining a random field over a network is a challenging task.

The electrical engineering and machine learning communities have been very active on the subject of networks, and the reader is referred to [Ortega](#page-27-4) [et al.](#page-27-4) [\[2018\]](#page-27-4) and [Chami et al.](#page-27-5) [\[2022\]](#page-27-5) for a comprehensive review.

For this manuscript, the network defines a topological structure representing the domain of definition of a given random field. This fact is exploited by [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0): endowing the network with a metric provides a metric space that is then (quasi) embeddable over Hilbert spaces. This is the crux of the argument that allows to build isotropic covariance functions over networks, where isotropy is understood with respect to two alternative metrics (the geodesic and the resistance metrics). A relevant remark is that networks endowed with metrics can be suitably represented through metric graphs. This approach is adopted by [Bolin and Lindgren](#page-27-6) [\[2011\]](#page-27-6), [Anderes](#page-27-0) [et al.](#page-27-0) [\[2020\]](#page-27-0) and [Bolin et al.](#page-27-7) [\[2022\]](#page-27-7). We shall make use of this fact subsequently. Scalar random fields that evolve temporally over graphs have been challenged by [Porcu et al.](#page-27-8) [\[2023\]](#page-27-8), [Filosi et al.](#page-27-9) [\[2023\]](#page-27-9) and [Tang and Zimmer](#page-28-0)[man](#page-28-0) [\[2020\]](#page-28-0).

The way a metric graph can be specified is certainly not unique. [Anderes](#page-27-0) [et al.](#page-27-0) [\[2020\]](#page-27-0) work over graphs with Euclidean edges — called generalised networks in [Porcu et al.](#page-27-8) [\[2023\]](#page-27-8) — which extend linear networks to nonlinear edges. Further, the random field defined over such structures can have realisations over any point over the edges, and not only in the nodes. Roughly, these are graphs where each edge is associated with an abstract set in bijective correspondence with a segment of the real line. This provides each edge with a Cartesian coordinate system to measure distances between any two points on that edge.

The fact that linear networks are overly limited to provide a suitable topological structure to random fields is well understood in the machine learning literature [\[Alsheikh et al.,](#page-28-1) [2014,](#page-28-1) [Hamilton et al.,](#page-28-2) [2017,](#page-28-2) [Borovitskiy](#page-28-3) [et al.,](#page-28-3) [2022\]](#page-28-3), as well as in spatial statistics [\[Cressie et al.,](#page-28-4) [2006,](#page-28-4) [Ver Hoef](#page-28-5) [et al.,](#page-28-5) [2006,](#page-28-5) [Peterson et al.,](#page-28-6) [2013,](#page-28-6) [2007,](#page-28-7) [Montembeault et al.,](#page-28-8) [2012,](#page-28-8) [Xiao](#page-29-0) [et al.,](#page-29-0) [2017,](#page-29-0) [Perry and Wolfe,](#page-29-1) [2013,](#page-29-1) [Deng et al.,](#page-29-2) [2014,](#page-29-2) [Baddeley et al.,](#page-29-3) [2017\]](#page-29-3).

#### **1.2 Challenge**

Our paper is unique according to the state of the art. The literature on vector-valued random fields on (linear or generalised) networks is elusive. This is not surprising: kernels on metric graphs are a very recent subject, and so far the main efforts have been focused to the case of scalar-valued random fields.

A subset of the graphs used in this paper is represented by the so-called Euclidean trees with a given number of leaves, which are substantially linear networks. For such a case, since a linear network is embedded into the two-dimensional Euclidean space, any matrix-valued covariance functions depending on the *ℓ*<sup>1</sup> norm (the so-called Manhattan distance) can be used as a covariance function for a vector-valued field on a linear network. The reader is referred to [Zastavnyi](#page-29-4) [\[2000\]](#page-29-4) for relevant results in terms of isometric embeddings. Unfortunately, there are two problems related to this fact:

- 1. To the knowledge of the authors, there are no models for matrix-valued covariances depending on the *ℓ*<sup>1</sup> distance;
- 2. Such constructions are no longer valid for the case of generalised networks.

Another relevant aspect is related to what we term *cross metrics* in the paper. To illustrate the principle, consider two random fields — call them  $Z_1$  and *Z*2. Since the network does not necessarily represent a geographic space, there is no reason to believe that the distance between  $Z_1(u)$  and  $Z_2(v)$ , for two different points *u, v* on the network, should be the same as the distance between  $Z_1(u)$  and  $Z_1(v)$  for instance. We take this aspect into account and devote attention to matrix-valued metrics.

#### **1.3 Our Constructions: Road Map**

Our constructions are based on the following steps. We provide here a concise description. Careful notation and terminology are established in Section [2.](#page-4-0) **The Road Map**

- 1. The purpose of the work is to construct a *p*-variate Gaussian random field, denoted  $\mathbf{Z} := \{ \mathbf{Z}(u) = (Z_1(u), \dots, Z_p(u))^\top, u \in \mathcal{G} \}$  throughout and defined over a metric graph,  $G$ , with a given matrix-valued covariance function that is isotropic, that is it depends on the *distance* between the points of the graph. Hence, the topological space  $\mathcal{G}$ , endowed with a proper matrix-valued (semi) metric  $\mathbf{D}: \mathcal{G} \times \mathcal{G} \to [0, +\infty)^{p \times p}$ , becomes a (semi) metric space  $(\mathcal{G}, \mathbf{D})$ .
- 2. Such a (semi) metric space can be (quasi) embedded on a suitable Hilbert space, which in turns allows to resort classical machinery for covariance functions on metric spaces [\[Schoenberg,](#page-29-5) [1942\]](#page-29-5).
- 3. Hence, a substantial part of the job is to build the multivariate metric **D**.
- 4. We then take advantage of isometric embedding arguments as in [An](#page-27-0)[deres et al.](#page-27-0) [\[2020\]](#page-27-0) to claim that, for a certain class of continuous mappings  $\psi : [0, +\infty) \to (0, +\infty)$ , the element-wise composition

$$
\mathbf{K}(u,v) := \psi\left(\mathbf{D}(u,v)\right), \qquad u, v \in \mathcal{G}, \tag{1}
$$

provides a valid matrix-valued covariance function.

5. We then generalise this construction by considering a matrix-valued class of continuous mappings  $\Psi : [0, +\infty)^{p \times p} \to [0, +\infty)^{p \times p}$  having elements  $\Psi_{ij}$ , such that the element-wise composition

<span id="page-3-0"></span>
$$
\mathbf{K}(u,v) := \mathbf{\Psi}(\mathbf{D}(u,v)) = [\Psi_{ij}(D_{ij}(u,v))]_{i,j=1}^p, \qquad u, v \in \mathcal{G}, \qquad (2)
$$

is a valid matrix-valued covariance function.

In turn, the construction of the multivariate metric **D** requires a collection of steps, which entails several technical challenges:

- **(a)** Following the construction in [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0), the vector-valued random field  $Z$  is defined as the sum of two random fields,  $Z_V$  and Z*E*, where the subscripts *V* and *E* stand, respectively, for the sets containing vertices and the edges associated with the metric graph, G. Both random fields are continuously indexed over the graph;
- **(b)** The random field  $\mathbf{Z}_V$  at any point of an edge,  $e \in E$ , is constructed through interpolation of the random field defined at the extremes of each edge (which are obviously vertices in *V* );
- **(c)** The multivariate metric is then checked for desiderata. Specifically, that the marginal metrics (those in the diagonal of **D**) respect the ingenious univariate condition provided by [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0). Further, the cross-elements in **D** are required to be homogeneous, in the sense that  $D_{ij} = D_{i'j'}$  for  $i \neq j$  and  $i' \neq j'$ , for  $D_{ij}$  a generic element of **D**.

For a subclass termed *Euclidean trees*, we provide multivariate kernels with compact support depending on the so-called Manhattan distance.

The structure of the paper is the following. Section [2](#page-4-0) provides the necessary background and notation. Results are provided in Sections [3](#page-12-0) and [4.](#page-22-0) Section [5](#page-26-0) concludes the paper. As proofs are rather technical and lengthy, they are deferred to Appendix [A.](#page-32-0) Further, Appendix [B](#page-51-0) contains a worked example that show some relevant property of the proposed construction.

Finally, to guide the reader into the structure of the results of this manuscript, we provide a road-map in Figure [1.](#page-5-0)

# <span id="page-4-0"></span>**2 Mathematical Background**

#### **2.1 Notation handout**

Throughout, p is an integer greater than 1 (the case  $p = 1$  has been treated by [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0)). Bold lowercase letters denote (deterministic) vectors (*e.g.* δ). Bold uppercase letters denote (deterministic) matrices (*e.g.* **A**). Bold uppercase italic letters denote random vectors (*e.g.*  $\bm{Z}$ ).  $\mathbf{A}^{\top}$ ,  $\bm{\delta}^{\top}$  and  $\bm{Z}^{\top}$ are the transposes of **A**,  $\delta$  and  $\mathbf{Z}$ , while  $\mathbf{A}^-$  stands for the Moore-Penrose inverse of **A**. Non-bold letters represent scalar (real-valued) quantities or

<span id="page-5-0"></span>Figure 1: Road-map of the main results in this manuscript. L, P, T and C stand for Lemma, Proposition, Theorem and Corollary, respectively. The suffix indicates that the result is stated in Appendix [A.](#page-32-0) The missing results have either no direct connection with the above results  $(L4.1, P6)$  $(L4.1, P6)$  $(L4.1, P6)$  or are essential for many others ([LA.1\)](#page-32-1).

non-numerical objects (sets, graphs, vertices, edges, or points). The (*i, j*)-th entry of **A** is denoted  $A_{ij}$ , while the *i*-th components of  $\delta$  and  $\mathbf{Z}$  are  $\delta_i$  and  $Z_i$ , respectively. The all-ones vector of size *n*, all-ones matrix of size  $n \times n$ , and identity matrix of size  $n \times n$  are denoted as  $\mathbf{1}_n$ ,  $\mathbf{1}_{n \times n}$  and  $\mathbf{I}_n$ , respectively. Finally, we define  $\mathbf{J}_n := \text{diag}\left[0, 0, \ldots, 0, 1\right]^\top (n \times n)$  diagonal matrix with only one non-zero entry).

Continuity, differentiation, integration and scalar- or matrix-valued functions (except power functions) involving matrices are understood as being performed element-wise. Concerning the power functions, **A**<sup>2</sup> is **A** multiperformed element-wise. Concerning the power functions,  $A^-$  is  $A$  multiplied by itself,  $\sqrt{A} = A^{1/2}$  is the principal square root of  $A$ , and  $A^{-1}$  is the inverse of **A** in the matrix sense. Products (*e.g.* **AB** or  $\mathbf{A}\delta$ ) and Kronecker products  $(e.g. \mathbf{A} \otimes \mathbf{B})$  are also understood in the matrix sense, not as element-wise operations.

### **2.2 Gaussian random fields on graphs with Euclidean edges**

The paper deals with a vector-valued Gaussian random field **Z** defined on a metric graph as exposed below. We assume a random field with zero-mean

vector and with a matrix-valued covariance matrix  $\mathbf{K}: \mathcal{G} \times \mathcal{G} \to \mathbb{R}^{p \times p}$  that is isotropic in the sense there exists a pair  $(\Psi, \mathbf{D})$ , with  $\Psi : [0, +\infty)^{p \times p} \to \mathbb{R}^{p \times p}$ and  $\mathbf{D}: \mathcal{G} \times \mathcal{G} \to [0, +\infty)^{p \times p}$ , both continuous, such that Equation [\(2\)](#page-3-0) is satisfied. We work with a specific class of metric graphs, termed graphs *with Euclidean edges* as being proposed by [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0) to generalise linear networks. The main idea underlying this construction is to associate every edge of the graph to a segment of the real line. As a consequence, it is possible to consider both the vertices and the points over the edges as actual points of the graph, where distances can be computed and random fields can be defined. As this is natural on linear networks as well, we stress that graphs with Euclidean edges do not have any restriction on the topology, *i.e.* the edges' lengths are free to vary and so are the connections between the vertices. Here we rephrase their original definition.

*Definition* 2.1 (Graph with Euclidean edges)*.* The type of topology considered by [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0) (to which the reader is referred for additional details and motivation) is called graph *with Euclidean edges*, denoted with a triple  $\mathcal{G} = (V, E, \{\varphi_e\}_{e \in E})$  throughout, where the elements are blended in the following way:

- (a)  $(V, E)$  has a graph structure, *i.e. V* is the set of vertices and  $E \subset$  $V \times V$  accounts for the edges. We assume that this graph is simple and connected, *i.e. V* is finite, the graph has not repeated edges or edges that join a vertex to itself and every pair of vertices is connected by a path.
- (b) Each edge  $e \in E$  is provided with a *length*  $\ell(e) > 0$  and a *weight*  $w(e) := 1/\ell(e)$ ; furthermore, it is associated with a unique abstract set, also denoted *e*, such that *V* and all the edge sets are mutually disjoint.
- (c) Let  $v_1$  and  $v_2$  be vertices connected by  $e \in E$ . Then,  $\varphi_e$  is a continuous and bijective mapping defined on  $e \cup \{v_1, v_2\}$ , such that  $\varphi_e$  maps  $e$  onto an open interval  $(0, \ell(e)) \subset \mathbb{R}$  and  $\{v_1, v_2\}$  onto  $\{0, \ell(e)\}.$

Henceforth, we shall assume the existence of a total order relation on the set of vertices *V* and that every edge is represented through the ordered pair  $(v_1, v_2)$ , where  $v_1 < v_2$ . By abuse of notation, we write  $u \in \mathcal{G}$  to denote a point on the graph: it can be either a vertex or a point on an edge. Each point  $u \in \mathcal{G}$  will be identified with the triple  $(\underline{u}, \overline{u}, \delta)$ , where:  $\underline{u} < \overline{u}$  are the

<span id="page-7-0"></span>Figure 2: Left: a graph with Euclidean edges, where the bijections  $\varphi_{e_1}$  and  $\varphi_{e_2}$  have been highlighted. Right: a Euclidean tree with 5 leaves where the role of  $\underline{u}$ ,  $\overline{u}$  and  $\delta_{e_3}(u)$  have been stressed. Adaptation of [Filosi et al.](#page-27-9) [\[2023,](#page-27-9) Figure 1].

endpoints of the edge *e* containing *u* and  $\delta \in [0,1]$  is the relative distance of *u* from <u>*u*</u>; formally:  $\delta = \delta(u) := w(e)\varphi_e(u)$ . Notice that, whenever *u* is a vertex, it is always possible to write  $u = (\underline{u}, \overline{u}, \delta)$  for  $\delta \in \{0, 1\}$ , though the choice of <u>u</u> and  $\overline{u}$  may not be unique. Finally, we use the notation  $e(u)$ , where  $e : \mathcal{G} \to E$ , to denote the edge that contains *u*. If  $u \in V$ , then  $e(u)$ is any of the edges that have an endpoint in *u*. It is in order to note that our definition slightly deviates from the original one in [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0): we do not require any distance consistency property, as we do not use the geodesic metric.

A graph with Euclidean edges is called an *Euclidean tree* if it has a tree structure, *i.e.* given any two points  $u_1, u_2 \in \mathcal{G}$ , there is exactly one path that connects  $u_1$  to  $u_2$ . A vertex of a Euclidean tree is called a *leaf* if it is connected to only one other vertex. Figure [2](#page-7-0) aims to clarify the notions introduced so far.

#### **2.3 Classes of matrices used in the paper**

An  $n \times n$  real matrix **A** is said to be *positive semidefinite* if and only if  $c^{\top}$ **A** $c \geq 0$  for all  $c \in \mathbb{R}^n$ , and *conditionally negative semidefinite* if and only if  $c^{\top}Ac \leq 0$  for all  $c \in \mathbb{R}^n$  such that  $\mathbf{1}_n^{\top}c = 0$ .

An  $n \times n$  matrix **L** is called *quasi-Laplacian* if and only if it is symmetric, positive semidefinite, and has exactly one null eigenvalue, with corresponding eigenvector **1***n*. A quasi-Laplacian matrix **L** is called *Laplacian* if and only if it has non-positive off-diagonal entries. Notice that Laplacian matrices arise naturally from weighted graphs: there is a bijection between the set of (positively) weighted, simple and undirected graphs and the set of Laplacian matrices [\[Devriendt,](#page-29-6) [2022,](#page-29-6) Subsection 2.1]. Henceforth, we will consider the Laplacian matrix of a given graph with Euclidean edges, with entries defined as [Devriendt](#page-29-6) [\[2022,](#page-29-6) Equation (1)]:

<span id="page-8-1"></span>
$$
L_{ij} = \begin{cases} \sum_{v \in V} w((v, v_i)) & \text{if } i = j \\ -w((v_i, v_j)) & \text{if } i \neq j, \end{cases}
$$
 (3)

with  $w((v_i, v_j))$  the weight of the edge joining vertices  $v_i$  and  $v_j$  if these vertices are connected, 0 otherwise.

Quasi-Laplacian matrices have been introduced as a generalisation of Laplacian matrices, as they will often appear in this manuscript. Their interpretation is slightly blurred, since, thinking about the bijection between Laplacian matrices and weighted graphs, it seems natural to interpret quasi-Laplacian matrices as Laplacian matrices of graphs with possibly negative weights. Nevertheless, as one may expect, quasi-Laplacian matrices share several properties of Laplacian matrices formally stated below.

<span id="page-8-0"></span>**Proposition 1.** *Let* **L** *be a quasi-Laplacian matrix partitioned as follows:*

$$
\mathbf{L} = \begin{bmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{B}^{\top} & \mathbf{C} \end{bmatrix},\tag{4}
$$

*where* **A** *and* **C** *are square matrices. Then the following statements hold.*

- *1.*  $B \neq 0$ *.*
- *2.* **A** *and* **C** *are strictly positive definite.*
- *3. Both*  $L/C := A BC^{-1}B^{\top}$  *and*  $L/A := C B^{\top}A^{-1}B$  *are quasi-Laplacian matrices, i.e. , the set of quasi-Laplacian matrices is closed under the Schur complement operation.*
- *4.* **L** <sup>−</sup> *is a quasi-Laplacian matrix.*

#### **2.4 Metrics used in the paper**

The work by [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0) shows that there is no unique way to define a metric over a graph with Euclidean edges. While the geodesic distance is physically intuitive, [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0) prove that it has very limited use in terms of available covariance functions. Further, when considering the geodesic distance not all graphs with Euclidean edges become *permissible* [\[Anderes et al.,](#page-27-0) [2020\]](#page-27-0), and a collection of technical restrictions is required. Alternatively, one can use the resistance metric, being a generalisation of the electric distance used for electric circuits [\[Klein and Randic,](#page-29-7) [1993\]](#page-29-7). To provide a description of the resistance metric, some further background is needed. Let *X* be a set and  $Z: X \to \mathbb{R}$  a square-integrable random field. The *variogram* of *Z* is defined via

$$
\gamma_Z: X \times X \to \mathbb{R}
$$
  

$$
(x_1, x_2) \mapsto \gamma_Z(x_1, x_2) := \text{Var} (Z(x_1) - Z(x_2)).
$$

Clearly, a variogram is always symmetric and non-negative valued. In addition, it is conditionally negative semidefinite, *i.e.* it satisfies  $[Chil\check{e}$  and [Delfiner,](#page-29-8) [2012\]](#page-29-8)

$$
\sum_{i,j=1}^{n} c_i c_j \gamma(x_i, x_j) \le 0 \tag{5}
$$

whenever  $\sum_{i=1}^{n} c_i = 0$ , for any  $x_1, \ldots, x_n \in X$ .

[Anderes et al.](#page-27-0) [\[2020\]](#page-27-0) define the resistance metric, denoting *d<sup>R</sup>* throughout, as the variogram of a random field  $Z$  on the graph with Euclidean edges  $\mathcal{G}$ , that is constructed *ad hoc* in order to be as much as possibly parenthetical to a Brownian bridge on the graph. Technicalities are deferred to their paper.

The concept of variogram can be generalised to the case of a zero-mean square-integrable vector-valued random field  $\boldsymbol{Z}$  on a non-empty set  $X$ , through the following lines. The *pseudo-variogram* of Z is defined through the identity

$$
\Gamma_{\mathbf{Z}} : X \times X \to [0, +\infty)^{p \times p}
$$
  

$$
(x_1, x_2) \mapsto \Gamma_{\mathbf{Z}}(x_1, x_2) := \left[ \mathbb{V}\text{ar}\left(Z_i(x_1) - Z_j(x_2)\right) \right]_{i,j=1}^p.
$$
 (6)

Straightforward calculations allow to rewrite the above as

<span id="page-10-0"></span>
$$
\Gamma_{\mathbf{Z}}(x_1,x_2) = (\text{diag} \,\mathbb{V}\text{ar}\,\mathbf{Z}(x_1)) \, \mathbf{1}_p{}^{\top} + \mathbf{1}_p \, (\text{diag} \,\mathbb{V}\text{ar}\,\mathbf{Z}(x_2)){}^{\top} - 2 \, \mathbb{C}\text{ov}\left(\mathbf{Z}(x_1), \mathbf{Z}(x_2)\right),\tag{7}
$$

where  $\mathbb{V}\text{ar}\mathbf{Z}(x_1)$  is the  $p \times p$  collocated variance-covariance matrix of  $\mathbf{Z}(x_1)$ , diag Var  $\mathbf{Z}(x_1)$  is the  $p \times 1$  vector containing the main diagonal of Var  $\mathbf{Z}(x_1)$ and  $\mathbb{C}$ ov  $(\mathbf{Z}(x_1), \mathbf{Z}(x_2)) := \mathbb{E}(\mathbf{Z}(x_1)\mathbf{Z}(x_2)^{\top})$ . The pseudo-variogram satis-fies the following properties [Dörr and Schlather, [2023\]](#page-29-9):

• for any  $x_1, x_2 \in X$ ,

<span id="page-10-2"></span><span id="page-10-1"></span>
$$
\Gamma_{\mathbf{Z}}(x_1, x_2) = \Gamma_{\mathbf{Z}}(x_2, x_1)^{\top};\tag{8}
$$

- for any  $x \in X$ , the diagonal entries of  $\Gamma_Z(x, x)$  are zero;
- $\Gamma_Z$  is  $1_p$ -conditionally negative semidefinite, *i.e.* for all  $n \in \mathbb{N}^+$ ,  $x_1, \ldots, x_n \in X$  and  $c_1, \ldots, c_n \in \mathbb{R}^p$  such that  $\mathbf{1}_p \subset \sum_{i=1}^n c_i = 0$ , it holds

<span id="page-10-3"></span>
$$
\sum_{i,j=1}^{n} \mathbf{c}_i^{\top} \mathbf{\Gamma}_\mathbf{Z}(x_i, x_j) \mathbf{c}_j \le 0.
$$
 (9)

In the following, we define the multivariate distance  $\mathbf{D}: X \times X \rightarrow$  $[0, +\infty)^{p\times p}$  via  $\mathbf{D}(x_1, x_2) := \mathbf{\Gamma}_{\mathbf{L}}(x_1, x_2)$ . It is in order to notice that at this point the matrix-valued distance **D** is *not* symmetric, *i.e.* in general  $D_{ij}(x_1, x_2) \neq D_{ji}(x_1, x_2)$ . This may pave the way for new asymmetric metrics.

### **2.5 Classes of functions and Schoenberg characterisations**

This section follows closely [Zastavnyi](#page-29-10) [\[2023\]](#page-29-10). A function  $k: X \times X \to \mathbb{R}$  is positive semidefinite if, for all  $n \in \{1, 2, \ldots\}$ ,  $x_1, \ldots, x_n \in X$  and  $c_1, \ldots, c_n \in X$ R, one has

$$
\sum_{i,j=1}^{n} c_i c_j k(x_i, x_j) \ge 0.
$$
 (10)

In addition, *k* is a strictly positive definite function if it is positive semidefinite and

$$
\sum_{i,j=1}^{n} c_i c_j k(x_i, x_j) = 0 \implies c_1 = \dots = c_n = 0.
$$
 (11)

The extension to the matrix-valued case reads as follows. A matrix-valued function  $\mathbf{K}: X \times X \to \mathbb{R}^{p \times p}$  is positive semidefinite if, for all  $n \in \{1, 2, \ldots\},\$  $c_1, \ldots, c_n \in \mathbb{R}^p$  and  $x_1, \ldots, x_n \in X$ , it holds:

<span id="page-11-1"></span>
$$
\sum_{i,j=1}^{n} \mathbf{c}_i^{\top} \mathbf{K}(x_i, x_j) \mathbf{c}_j \ge 0.
$$
 (12)

In addition, **K** is strictly positive definite if it is positive semidefinite and the condition

$$
\sum_{i,j=1}^{n} \mathbf{c}_i^{\top} \mathbf{K}(x_i, x_j) \mathbf{c}_j = 0 \tag{13}
$$

implies that there exists a pair  $i \neq j$  such that  $x_i = x_j$  or  $c_1 = \cdots = c_n =$ 0. A relevant result for our developments is coming from Proposition 1 in [Zastavnyi](#page-29-10) [\[2023\]](#page-29-10), which is formally stated for a neater exposition.

### <span id="page-11-0"></span>**Proposition 2.** Let  $\mathbf{K}: X \times X \to \mathbb{R}^{p \times p}$ . Then, the following are equivalent:

- **K** *is positive semidefinite;*
- *for all*  $n \in \{1, 2, \ldots\}$  *and for all*  $x_1, \ldots, x_n \in X$ *, the np*  $\times$  *np block*  $\textit{matrix } \mathbf{C} := [C_{ij}]_{i,j=1}^{np} := [\mathbf{K}(x_i,x_j)]_{i,j=1}^{n} \textit{ is positive semidefinite, i.e. },$  $c^{\top}$ **C** $c \geq 0$  for any  $c \in \mathbb{R}^{np}$ .

A function  $\psi : [0, +\infty) \to [0, +\infty)$  is called *completely monotone* if it is continuous on  $[0, +\infty)$ , infinitely differentiable on  $(0, +\infty)$  and for each  $i \in \mathbb{N}$ it holds

$$
(-1)^i \psi^{(i)}(x) \ge 0,
$$

where  $\psi^{(i)}$  denotes the *i*<sup>th</sup> derivative of  $\psi$  and  $\psi^{(0)} := \psi$ . A function  $\psi$ :  $[0, +\infty) \rightarrow [0, +\infty)$  is completely monotone if and only if it is the Laplace transform of a (unique) finite Borel measure  $\mu$  on [0, + $\infty$ ), *i.e.* 

$$
\psi(x) = \int_0^{+\infty} \exp(-tx) \,\mu(\mathrm{d}t), \quad x \in [0, +\infty). \tag{14}
$$

A function  $g : [0, +\infty) \to [0, +\infty)$  is called a *Bernstein function* if g in infinitely differentiable on  $[0, +\infty)$  and  $g^{(1)}$  is a completely monotone function.

Our expository material is now completed by reporting Theorem 5 of [Zastavnyi](#page-29-10) [\[2023\]](#page-29-10).

<span id="page-12-1"></span>**Theorem 2.2.** Let  $\psi : [0, +\infty) \to (0, +\infty)$  be a non-constant completely *monotone function,*  $g : [0, +\infty) \to [0, +\infty)$  *be a Bernstein function and let*  $\Gamma_Z: X \times X \to [0, +\infty)^{p \times p}$ , for a non-empty set *X.* If, for all  $x_1, x_2 \in X$ ,  $\Gamma_{\mathbf{Z}}^{\top}(x_1, x_2) = \Gamma_{\mathbf{Z}}(x_2, x_1)$  and  $\Gamma_{\mathbf{Z}}$  is  $\mathbf{1}_p$ -conditionally negative semidefinite, *then, for all*  $\xi > 0$ *,* 

$$
(x_1, x_2) \mapsto \psi\Big(\xi g\left(\Gamma_Z(x_1, x_2)\right), \qquad x_1, x_2 \in X,
$$

*where*  $\psi$  *and*  $g$  *are applied element-wise, is a positive semidefinite function on X.*

# <span id="page-12-0"></span>**3 General Results**

The following notation will ease the exposition throughout:

- *n* is the number of vertices of the graph  $G$  (cardinality of  $V$ ),
- **L** is the Laplacian matrix of  $\mathcal{G}$  as per Equation [\(3\)](#page-8-1),
- $\Sigma := \mathbf{L}^-$  is the Moore-Penrose inverse of  $\mathbf{L}$ ,
- $\Lambda$  and **W** are the eigenvalues and eigenvectors matrices of  $\Sigma$ , *i.e.*  $\Sigma$  = **W**Λ**W**<sup>⊤</sup>,
- for two matrices  $\mathbf{A}, \mathbf{B}$  of the same size and for a positive integer  $p$ , we define

$$
\mathcal{M}_p(\mathbf{A}, \mathbf{B}) := \mathcal{M}_p\begin{pmatrix} \mathbf{A} \\ \mathbf{B} \end{pmatrix} := \mathbf{I}_p \otimes \mathbf{A} + (\mathbf{1}_{p \times p} - \mathbf{I}_p) \otimes \mathbf{B} = \begin{bmatrix} \mathbf{A} & \mathbf{B} & \dots & \mathbf{B} \\ \mathbf{B} & \mathbf{A} & \dots & \mathbf{B} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{B} & \mathbf{B} & \dots & \mathbf{A} \end{bmatrix} .
$$
\n(15)

The construction provided in this section extends, to the matrix-valued case, that in [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0). Specifically, we shall consider a vectorvalued random field,  $Z$ , that is obtained through the identity

<span id="page-12-2"></span>
$$
\mathbf{Z}(u) := \mathbf{Z}_V(u) + \mathbf{Z}_E(u), \qquad u \in \mathcal{G}.\tag{16}
$$

In turn, the random fields  $Z_V$  and  $Z_E$  obeys to different construction principles. Specifically,  $Z_V$  is a multivariate Gaussian random vector on the vertices and is linearly interpolated on the edges, whilst  $\mathbb{Z}_E$  is zero on the vertices and adds some variability on the edges. We note that [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0) consider this construction for the case  $p = 1$  and this entails the use of a specific class of variograms that are then used to build the resistance metric,  $d_R$ . It is not surprising that our construction will rely on the pseudovariogram  $\Gamma_Z$  for the generalisation to the *p*-variate setting with  $p > 1$ . While these constructions are mathematically involved, a simple description is provided here, with technicalities and proofs deferred to Appendix [A.](#page-32-0)

#### <span id="page-13-1"></span>**3.1 Construction for the Vertices**

This section provides a construction for the random field Z*<sup>V</sup>* as per the identity [\(16\)](#page-12-2). While the search for metrics is probably unlimited in terms of alternatives, our spectrum is suitably restricted by providing two *desiderata*, denoted  $\mathbb D$  throughout.

- D1: The construction [\(16\)](#page-12-2) needs to provide a pseudo-variogram  $\Gamma_Z$  for which the diagonal entries should obey to the variogram construction as in [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0).
- $\mathbb{D}2$ : The multivariate random field  $\mathbb{Z}_V$  on V should enjoy a homogeneous conditional independence structure. More precisely, we set the blockprecision matrix  $\Theta$  of  $Z_V$  to have the following structure:

<span id="page-13-0"></span>
$$
\mathbf{\Theta} = \mathcal{M}_p \begin{pmatrix} \mathbf{Q} \\ -\alpha \mathbf{I}_n \end{pmatrix},\tag{17}
$$

where  $\alpha$  is a positive real value and **Q** is a suitable  $n \times n$  matrix that will be defined next. This means that, for  $i \neq j$  and  $v_1 \neq v_2$ ,  $Z_{V,i}(v_1)$ and  $Z_{V,j}(v_2)$  are conditionally independent given everything else.

<span id="page-14-3"></span>Define the  $n \times n$  matrices:

$$
\mathbf{Q} := \frac{1}{2} \left( \mathbf{L} + \alpha (p-2) \mathbf{I}_n + \sqrt{\mathbf{L}^2 - 2\alpha (p-2) \mathbf{L} + \alpha^2 p^2 \mathbf{I}_n} \right)
$$
(18)  

$$
= \frac{1}{2} \mathbf{W} \left( \mathbf{\Lambda}^- + \alpha (p-2) \mathbf{I}_n + \sqrt{(\mathbf{\Lambda}^-)^2 - 2\alpha (p-2) \mathbf{\Lambda}^- + \alpha^2 p^2 \mathbf{I}_n} \right) \mathbf{W}^\top,
$$
(19)

$$
\mathbf{X} := \frac{1}{\alpha(p-1)} \left( \mathbf{\Sigma} \mathbf{Q} - \mathbf{I}_n \right) \tag{20}
$$

$$
= \frac{1}{2\alpha(p-1)} \mathbf{W} \left( \alpha(p-2) \mathbf{\Lambda} + \sqrt{\mathbf{I}_n - \mathbf{J}_n - 2\alpha(p-2) \mathbf{\Lambda} + \alpha^2 p^2 \mathbf{\Lambda}^2} - \mathbf{I}_n - \mathbf{J}_n \right) \mathbf{W}^\top.
$$
\n(21)

Notice that in Equations [\(19\)](#page-14-1) and [\(21\)](#page-14-2) the principal square root coincides with the element-wise square root, being its arguments diagonal matrices. These equations have been established from Equations [\(18\)](#page-14-3) and [\(20\)](#page-14-4) by using the fact that **W** is an orthogonal matrix and that  $\Lambda \Lambda^- = I_n - J_n$  insofar as the first  $p-1$  diagonal entries of  $\Lambda$  are positive and the last diagonal entry is zero. In addition, we define the two positive constants

<span id="page-14-4"></span><span id="page-14-2"></span><span id="page-14-1"></span>
$$
k_1 := \frac{p-1}{\alpha np^2} \qquad k_2 := \frac{p^2 - p + 1}{\alpha np^2(p-1)},
$$

and the  $n \times n$  matrices

$$
\tilde{\mathbf{\Sigma}} := \mathbf{\Sigma} + k_1 \mathbf{1}_{n \times n} \qquad \tilde{\mathbf{X}} := \mathbf{X} + k_2 \mathbf{1}_{n \times n}.
$$

Although these definitions may appear peculiar, they are the only solution to the *desiderata* D previously stated and are crucial to define the random field  $\mathbf{Z}_V$ . We start with the vertices, where  $\mathbf{Z}_V$  is assumed a zero-mean *p*-variate Gaussian random vector  $Z_V|_V : V \to \mathbb{R}^p$  having covariance matrix-valued function

<span id="page-14-5"></span>
$$
\mathbb{C}\text{ov}\left(\mathbf{Z}_{V}(v_{1}),\mathbf{Z}_{V}(v_{2})\right) := \mathcal{M}_{p}\left(\frac{\tilde{\mathbf{\Sigma}}[v_{1},v_{2}]}{\tilde{\mathbf{X}}[v_{1},v_{2}]}\right) \in \mathbb{R}^{p \times p}.
$$
 (22)

Checking the positive semidefiniteness of [\(22\)](#page-14-5) relies on a result of independent interest which implies that both  $\Theta$  and  $\Theta^-$  are positive semidefinite matrices. We state this formally below.

<span id="page-14-0"></span>**Proposition 3.** *The matrix* Θ *defined in Equation [\(17\)](#page-13-0) and its Moore-Penrose inverse* Θ<sup>−</sup> *are quasi-Laplacian.*

<span id="page-15-1"></span>**Proposition 4.** *The function defined in [\(22\)](#page-14-5) is positive semidefinite.*

Once  $Z_V$  is defined over the vertices, the corresponding values over the edges are attained through a sheer linear interpolation. Namely, for  $u =$  $(\underline{u}, \overline{u}, \delta(u)) \in \mathcal{G}$ , we set

<span id="page-15-3"></span>
$$
\mathbf{Z}_V(u) := (1 - \delta(u))\mathbf{Z}_V(\underline{u}) + \delta(u)\mathbf{Z}_V(\overline{u}).
$$
\n(23)

#### **3.2 Construction for the Edges**

We define Z*<sup>E</sup>* as a *p*-variate zero-mean Gaussian random field independent of  $Z_V$  whose covariance matrix-valued function is:

<span id="page-15-2"></span>
$$
\mathbb{C}\text{ov}\left(\mathbf{Z}_{E}(u_1),\mathbf{Z}_{E}(u_2)\right) := \mathbb{1}\left(e_1 = e_2\right)\ell(e_1)\left(\delta_1 \wedge \delta_2 - \delta_1 \delta_2\right)\mathcal{M}_p\begin{pmatrix}1\\ \beta\end{pmatrix} \in [0, +\infty)^{p \times p},\tag{24}
$$

for  $e_i := e(u_i)$ ,  $\delta_i := \delta(u_i)$ ,  $i \in \{1, 2\}$  and where  $\beta \in [0, 1]$  is a fixed parameter. Notice that  $\mathbf{Z}_E\Big|_{e_1}$  is independent from  $\mathbf{Z}_E\Big|_{e_2}$  whenever  $e_1 \neq e_2$ , in addition  $\ell(e_1)$  ( $\delta_1 \wedge \delta_2 - \delta_1 \delta_2$ ) is the covariance function of a standard Brownian bridge on  $[0, \ell(e_1)]$ , whilst  $\mathcal{M}_p(1, \beta)$  is positive semidefinite for  $\beta \in [0, 1]$ . This ensures that [\(24\)](#page-15-2) is positive semidefinite, as the element-wise product of positive semidefinite functions is itself positive semidefinite.

#### **3.3 Compendium**

The following result comes directly from the above definitions.

<span id="page-15-0"></span>**Proposition 5.** Let  $\mathbf{K}_{\mathbf{Z}_V}$ ,  $\mathbf{K}_{\mathbf{Z}_E}$  be the covariance mappings associated re*spectively with the random fields*  $\mathbf{Z}_V$  *and*  $\mathbf{Z}_E$ *. Then, it is true that* 

$$
\mathbf{K}_{\mathbf{Z}_V}(u_1, u_2) = \mathcal{M}_p\begin{pmatrix} \delta_{1,V}^{\top} \tilde{\Sigma} \delta_{2,V} \\ \delta_{1,V}^{\top} \tilde{\mathbf{X}} \delta_{2,V} \end{pmatrix} \in \mathbb{R}^{p \times p},
$$
(25)

 $for u_i = (\underline{u}_i, \overline{u}_i, \delta_i) \in \mathcal{G}$  ( $i \in \{1, 2\}$ ), and where  $\delta_{i,V}$  is the *n*-dimensional *vector whose entries are*

<span id="page-15-4"></span>
$$
\delta_{i,V} := \begin{cases}\n1 - \delta_i & \text{if } v = \underline{u}_i \\
\delta_i & \text{if } v = \overline{u}_i, v \in V. \\
0 & \text{otherwise}\n\end{cases} \tag{26}
$$

*Further, it is true that*

$$
\mathbf{K}_{\mathbf{Z}_E}(u_1, u_2) = \mathcal{M}_p\begin{pmatrix} \mathbb{1} \left( e_1 = e_2 \right) \ell(e_1) \left( \delta_1 \wedge \delta_2 - \delta_1 \delta_2 \right) \\ \beta \mathbb{1} \left( e_1 = e_2 \right) \ell(e_1) \left( \delta_1 \wedge \delta_2 - \delta_1 \delta_2 \right) \end{pmatrix}.
$$

As a direct implication of Proposition  $5$  in concert with the fact that  $Z_V$ and  $\mathbf{Z}_E$  are independent, we obtain the following.

<span id="page-16-1"></span>**Corollary 1.** *It is true that*

$$
\mathbf{K}_{\mathbf{Z}}(u_1, u_2) = \mathbf{K}_{\mathbf{Z}_V}(u_1, u_2) + \mathbf{K}_{\mathbf{Z}_E}(u_1, u_2)
$$
\n
$$
= \mathcal{M}_p \left( \begin{array}{c} \n\boldsymbol{\delta}_{1,V}^{\mathrm{T}} \tilde{\boldsymbol{\Sigma}} \boldsymbol{\delta}_{2,V} + \mathbb{1} \left( e_1 = e_2 \right) \ell(e_1) \left( \delta_1 \wedge \delta_2 - \delta_1 \delta_2 \right) \\ \n\boldsymbol{\delta}_{1,V}^{\mathrm{T}} \tilde{\boldsymbol{\Sigma}} \boldsymbol{\delta}_{2,V} + \beta \mathbb{1} \left( e_1 = e_2 \right) \ell(e_1) \left( \delta_1 \wedge \delta_2 - \delta_1 \delta_2 \right) \end{array} \right). \tag{27}
$$

We are now able to derive the matrix-valued metric associated with the random field **Z** in [\(16\)](#page-12-2). To do so, we let  $\mathbf{D}: \mathcal{G} \times \mathcal{G} \to [0, +\infty)^{p \times p}$  be the pseudo-variogram of Z, *i.e.*

<span id="page-16-4"></span><span id="page-16-3"></span>
$$
\mathbf{D}(u_1, u_2) := \mathbf{\Gamma}_\mathbf{Z}(u_1, u_2) = [\text{Var}\left(Z_i(u_1) - Z_j(u_2)\right)]_{i,j=1}^p. \tag{28}
$$

A straightforward application of Equation [\(7\)](#page-10-0) in concert with tedious calculations provides the following fact.

<span id="page-16-2"></span>**Proposition 6.** *It is true that*

$$
\mathbf{D}(u_1, u_2) = \mathcal{M}_p \begin{pmatrix} (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^\top \tilde{\boldsymbol{\Sigma}} (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V}) \\ \boldsymbol{\delta}_{1,V}^\top \tilde{\boldsymbol{\Sigma}} \boldsymbol{\delta}_{1,V} + \boldsymbol{\delta}_{2,V}^\top \tilde{\boldsymbol{\Sigma}} \boldsymbol{\delta}_{2,V} - 2 \boldsymbol{\delta}_{1,V}^\top \tilde{\boldsymbol{\mathbf{X}}} \boldsymbol{\delta}_{2,V}) \end{pmatrix} + \mathcal{M}_p \begin{pmatrix} (\ell(e_1)\delta_1(1-\delta_1) + \ell(e_2)\delta_2(1-\delta_2) - 2\mathbb{I} (e_1 = e_2) \ell(e_1) (\delta_1 \wedge \delta_2 - \delta_1 \delta_2) \\ \ell(e_1)\delta_1(1-\delta_1) + \ell(e_2)\delta_2(1-\delta_2) - 2\beta \mathbb{I} (e_1 = e_2) \ell(e_1) (\delta_1 \wedge \delta_2 - \delta_1 \delta_2) \end{pmatrix},
$$
\n(29)

*for*  $u_1, u_2 \in \mathcal{G}$ *, with notation as in Proposition [5.](#page-15-0)* 

Notice that the former line coincides with the contribution of the random field  $\mathbf{Z}_V$ , whilst the latter is the contribution of  $\mathbf{Z}_E$ .

We describe below some properties of the metric **D** provided through our construction.

<span id="page-16-0"></span>**Proposition 7.** *The matrix-valued expression [\(28\)](#page-16-3) satisfies properties similar to the (real-valued) quasi-metrics, i.e. it satisfies:*

- *1.*  $D_{ij}(u_1, u_2) \geq 0$ ;
- 2.  $D_{ij}(u_1, u_2) = 0 \iff u_1 = u_2 \text{ and } i = j;$
- *3.*  $\mathbf{D}(u_1, u_2) = \mathbf{D}(u_1, u_2)^\top = \mathbf{D}(u_2, u_1) = \mathbf{D}(u_2, u_1)^\top$  for any  $u_1, u_2 \in \mathcal{G}$ ;
- *4. The mapping*  $(u_1, u_2) \mapsto \mathbf{D}(u_1, u_0) \mathbf{A} + \mathbf{A}^\top \mathbf{D}(u_0, u_2) \mathbf{D}(u_1, u_2) \mathbf{A}^\top \mathbf{D}(u_0, u_0) \mathbf{A}$ *is positive semidefinite for any*  $u_0 \in \mathcal{G}$  *and any*  $p \times p$  *matrix* **A** *such that*  $\mathbf{A}^{\top} \mathbf{1}_p = \mathbf{1}_p$ *;*
- *5. The matrices*  $D(u_1, u_2) D(u_0, u_0)$  *and*  $2D(u_1, u_0) + 2D(u_2, u_0) D(u_1, u_2)$ −  $3\mathbf{D}(u_0, u_0)$  are symmetric and positive semidefinite for any  $u_0, u_1, u_2 \in$ G*.*

Note the resemblance between the fourth property in Proposition [7](#page-16-0) and the second statement in [Zastavnyi](#page-29-10) [\[2023,](#page-29-10) Proposition 4].

<span id="page-17-1"></span>**Proposition 8.** Let G be a graph with Euclidean edges and let  $\mathbf{D}$  :  $\mathcal{G} \times \mathcal{G} \rightarrow$  $[0, +\infty)^{p \times p}$  as defined in [\(28\)](#page-16-3) and having elements  $D_{ij}$ ,  $i, j = 1, \ldots, p$ . Then, *the following properties hold:*

- *1. for all*  $i \in \{1, \ldots, p\}$ *, the distance*  $D_{ii}$  *coincides with the resistance distance defined by [Anderes et al.](#page-27-0)* [\[2020\]](#page-27-0), *i.e.*  $D_{ii}(u_1, u_2) = d_R(u_1, u_2)$ ;
- 2. the distance **D** is matrix-homogeneous, i.e. for every  $i \neq j$  and  $i' \neq j'$ , *we have*  $D_{ij}(u_1, u_2) = D_{i'j'}(u_1, u_2)$  and  $D_{ii}(u_1, u_2) = D_{i'i'}(u_1, u_2)$ .

Albeit counter-intuitive, the distance within the same variable is not always less than the same distance among variables. In formulae,  $D_{ii}(u_1, u_2) \nleq$  $D_{ii}(u_1, u_2)$ , in general. Appendix [B](#page-51-0) shows this fact through a worked example.

The following result illustrates some asymptotic properties of the proposed metric.

<span id="page-17-2"></span>**Proposition 9.** *Let* G *be a graph with Euclidean edges and let* **Q** *and* **X** *as defined in Equations [\(18\)](#page-14-3)-[\(21\)](#page-14-2). Then, the asymptotic results indicated in Table [1](#page-18-0) hold.*

<span id="page-17-0"></span>**Theorem 3.1.** Let G be a graph with Euclidean edges and  $\mathbf{D} : \mathcal{G} \times \mathcal{G} \rightarrow$  $[0, +\infty)^{p\times p}$  the distance defined at [\(28\)](#page-16-3). In addition, let  $\psi : [0, +\infty) \rightarrow$  $(0, +\infty)$  *be a non-constant completely monotone function and*  $q : [0, +\infty) \rightarrow$ 

<span id="page-18-0"></span>Table 1: Asymptotic results with respect to *p* and  $\alpha$ . In the 4<sup>th</sup> row,  $0 < \tau \leq$  $\lambda$ <sub>*n*−1</sub>, with  $\lambda$ <sub>*n*−1</sub> being the smallest positive eigenvalue of Σ, while in the last row,  $\tau \geq \lambda_1$ . In the last column, the results involving  $d_R(u_1, u_2)$  hold only for  $\beta \to 1$  (the other result holds for every  $\beta \in [0,1]$ ). Emilio, per essere formali qui dovremmo modificare le prime due righe della colonna Q e metterci il limite: sei d'accordo o lasciamo così?

$\mathcal{D}$	$\alpha$			$D_{ij}(u_1, u_2)$ for $i \neq j$
$+\infty$		fixed $\alpha(p-1)\mathbf{I}_n$		$d_R(u_1, u_2)$
fixed	$+\infty$	$\alpha(p-1)\mathbf{I}_n$		$d_R(u_1, u_2)$
fixed	$0^+$		$\frac{1}{\alpha n(p-1)}\mathbf{1}_{n\times n}$	$\alpha np$
$+\infty$	$p\tau$	$\mathbf{I}_n$	$\boldsymbol{\Sigma} - \tau \mathbf{I}_n$	$d_R(u_1, u_2) + 2\tau \boldsymbol{\delta}_{1,V}^\top \boldsymbol{\delta}_{2,V}$
$+\infty$		$\mathbf{L} + \frac{1}{n\tau} \mathbf{1}_{n\times n}$	$-\frac{\tau}{n}\mathbf{1}_{n\times n}$	$d_R(u_1, u_2) + \frac{2\tau}{n} + 2\delta_{1,V}^\top \mathbf{X} \delta_{2,V}$

 $[0, +\infty)$  *a Bernstein function. Then, for every*  $\xi > 0$ *, the mapping* **K** *defined as*

<span id="page-18-1"></span>
$$
(u_1, u_2) \mapsto \mathbf{K}(u_1, u_2) = \psi(\xi g(\mathbf{D}(u_1, u_2))), \tag{30}
$$

*where ψ and g are applied element-wise, is a valid covariance function. If, in addition,*  $\psi(0) = 1$ *, then* [\(30\)](#page-18-1) *is a valid correlation function.* 

One of the main drawbacks of this construction is that the distance is homogeneous (see Proposition [8\)](#page-17-1). Consequently, not only do the resulting matrix-valued covariance function [\(30\)](#page-18-1) assigns the same marginal covariance for all the variables, *i.e.*  $\psi(\xi g(D_{ii}(u_1, u_2))) = \psi(\xi g(d_R(u_1, u_2)))$  for any  $u_1, u_2 \in \mathcal{G}$  and any  $i \in \{1, \ldots, p\}$ , but also the cross-covariance between two different variables is independent from the variables themselves, *i.e.*  $\psi(\xi g(D_{ij}(u_1, u_2)))$  does not depend on *i, j* as long as  $i \neq j$ . Such a restriction can be easily circumvented. Let  $[\rho_{ij}]_{i,j=1}^p$  be a collocated correlation matrix, *e.g.*,  $\rho_{ii} = 1$  and  $-1 \leq \rho_{ij} \leq 1$  when  $i \neq j$ , and the matrix being symmetric and positive semidefinite. Let  $\boldsymbol{\sigma} = (\sigma_1, \ldots, \sigma_p)^\top$  with  $\sigma_i > 0$ for  $i = 1, \ldots, p$ . Let **K** be the mapping in [\(30\)](#page-18-1) and define the mapping  $\widetilde{\mathbf{K}}$  :  $\mathcal{G} \times \mathcal{G} \to \mathbb{R}^{p \times p}$  with entries

$$
K_{ij}(u_1,u_2):=\sigma_i\sigma_j\rho_{ij}K_{ij}(u_1,u_2), \quad i,j=1,\ldots,p, \quad u_1,u_2\in\mathcal{G}.
$$

Then, by straight application of the Schur product theorem, one gets that **K**<sup>f</sup> is a positive semidefinite matrix-valued function. However, all the marginal covariances (diagonal entries of  $\bf{K}$ ) are proportional, and the same happens for all the cross-covariances (off-diagonal entries of  $\bf{K}$ ), which is still restrictive. The results following throughout allow to circumvent such a limitation.

#### **3.4 Generalisations**

An interesting generalisation is provided below.

<span id="page-19-0"></span>**Theorem 3.2.** Let  $\theta \in (0,1]$ . Let  $\mathbf{F} : [0, +\infty) \to \mathbb{R}^{p \times p}$  be a Borel measure *such that, for any fixed*  $\xi > 0$ *, the matrix*  $\mathbf{F}(d\xi)$  *is symmetric and positive semidefinite. Let*  $\mathbf{D}$  *as in Equation [\(28\)](#page-16-3)* and let  $\Psi(\cdot) : [0, +\infty) \to \mathbb{R}^{p \times p}$  be a *continuous mapping determined through*

<span id="page-19-1"></span>
$$
\Psi(\mathbf{D}) := \left[ \int_0^{+\infty} \exp(-\xi D_{ij}^\theta) F_{ij}(\mathrm{d}\xi) \right]_{i,j=1}^p, \tag{31}
$$

*where*  $F_{ij}(\text{d} \cdot)$  *and*  $D_{ij}$  *are the*  $(i, j)$ *-th entries of*  $\mathbf{F}(\text{d} \cdot)$  *and*  $\mathbf{D}$ *, respectively. Then,* Ψ *is the covariance function of a Gaussian random field* Z *constructed according to the addition principle [\(16\)](#page-12-2).*

As a first application of this result, we adapt a construction that has been originally provided by [Porcu et al.](#page-30-0) [\[2018\]](#page-30-0) in Euclidean spaces and working with the classical Euclidean norm. The Shkarofsky-Gneiting family of functions  $\mathcal{SG}_{\alpha,\beta,\nu}(\cdot)$  is defined on  $[0,+\infty)$  through

$$
\mathcal{SG}_{\alpha,\beta,\nu}(t) = \left(1 + \frac{t}{\beta}\right)^{-\nu/2} \frac{\mathcal{K}_{\nu}\left(\frac{1}{\sqrt{\alpha}}\sqrt{\beta + t}\right)}{\mathcal{K}_{\nu}\left(\sqrt{\frac{\beta}{\alpha}}\right)}, \qquad t \ge 0,
$$
 (32)

where  $\mathcal{K}_{\nu}$  stands for the modified Bessel function of the second kind. Arguments therein show that  $\mathcal{SG}$  is the Laplace transform of a positive and bounded function. The family is very interesting as it admits the special limit cases

$$
\mathcal{SG}_{\alpha,0,-\nu}(t) = \mathcal{M}_{\alpha,\nu}(t) := \frac{2^{1-\nu}}{\Gamma(\nu)} \left(\frac{t}{\alpha}\right)^{\nu/2} \mathcal{K}_{\nu}\left(\sqrt{\frac{t}{\alpha}}\right), \qquad t \ge 0,
$$

for  $\alpha, \nu > 0$ , and

$$
\mathcal{SG}_{0,\beta,\nu}(t) = \mathcal{C}_{\beta,\nu}(t) := \left(1 + \frac{t}{\beta}\right)^{-\nu}, \qquad t \ge 0,
$$

for  $\beta, \nu > 0$ , where  $\mathcal{M}_{\alpha,\nu}(t) = \frac{2^{1+\nu}}{\Gamma(-\nu)}$  $\Gamma(-\nu)$  <sup>√</sup> √ *t α*  $\int^{-\nu}$   $\mathcal{K}_{-\nu}$   $\left(\frac{\sqrt{t}}{\sqrt{0}}\right)$ *α*  $\big), \ \alpha > 0, \nu > 0 \text{ and}$ where  $\mathcal{C}_{\alpha,a,\nu}(t) = \left(1 + \frac{t^a}{\alpha}\right)$ *α*  $\int_{-\infty}^{\infty}$ ,  $\alpha > 0$ ,  $\nu > 0$ . We consider the case  $p = 2$  and define the bivariate Shkarofsky-Gneiting mapping  $\mathcal{SG}_2 : [0, +\infty)^{2 \times 2} \to \mathbb{R}^{2 \times 2}$ through

<span id="page-20-1"></span>
$$
\mathbf{SG}_2(\mathbf{D}) = \begin{bmatrix} \sigma_1^2 \, \mathbf{SG}_{\alpha_1, \beta_1, \nu_1}(D_{11}^{\theta}) & \sigma_1 \sigma_2 \rho \, \mathbf{SG}_{\alpha_{12}, \beta_{12}, \nu_{12}}(D_{12}^{\theta}) \\ \sigma_1 \sigma_2 \rho \, \mathbf{SG}_{\alpha_{12}, \beta_{12}, \nu_{12}}(D_{12}^{\theta}) & \sigma_2^2 \, \mathbf{SG}_{\alpha_{2}, \beta_{2}, \nu_{2}}(D_{22}^{\theta}) \end{bmatrix}, \quad (33)
$$

where  $\theta \in (0, 1], (\sigma_1, \sigma_2, \alpha_1, \alpha_2, \alpha_{12}, \beta_1, \beta_2, \beta_{12}) \in (0, +\infty)^8$  and  $(\rho, \nu_1, \nu_2, \nu_{12}) \in$  $\mathbb{R}^4$ . The following result is a straightforward combination of Theorem [3.2](#page-19-0) with the arguments in Theorem 1 of [Porcu et al.](#page-30-0) [\[2018\]](#page-30-0), so that the proof is omitted.

<span id="page-20-0"></span>**Theorem 3.3.** *Let* **SG**<sup>2</sup> *be the matrix-valued function defined by Equation [\(33\)](#page-20-1). If either*

**A.** PARSIMONIOUS  $\mathcal{SG}_2$ :  $\alpha_{12} = \frac{1}{2}$ 2 *α*1*α*<sup>2</sup>  $\frac{\alpha_1 \alpha_2}{(\alpha_1 + \alpha_2)}, \ \beta_{12} = \frac{1}{2}$  $\frac{1}{2}(\beta_1+\beta_2), \nu_{12}=\frac{1}{2}$  $\frac{1}{2}(\nu_1+\nu_2),$ *and*

$$
|\rho| \le \sqrt{\frac{A(\alpha_1, \beta_1, \nu_1)A(\alpha_2, \beta_2, \nu_2)}{A^2(\alpha_{12}, \beta_{12}, \nu_{12})}},
$$

*with*  $A(\cdot, \cdot, \cdot)$  *defined as* 

$$
A(\alpha, \beta, \nu) = \frac{2^{\nu - 1} (\alpha \beta)^{\nu/2}}{\mathcal{K}_{\nu} (\sqrt{\frac{\beta}{\alpha}})},
$$

*or*

**B.** FULL  $\mathcal{SG}_2$ :  $\alpha_{12} < \frac{1}{2}$ 2 *α*1*α*<sup>2</sup>  $\frac{\alpha_1 \alpha_2}{(\alpha_1 + \alpha_2)}, \ \beta_{12} > \frac{1}{2}$  $\frac{1}{2}(\beta_1 + \beta_2), \nu_{12} \neq \frac{1}{2}$  $\frac{1}{2}(\nu_1+\nu_2), \text{ and}$ 

$$
|\rho| \le \sqrt{\frac{A(\alpha_1, \beta_1, \nu_1)A(\alpha_2, \beta_2, \nu_2)}{A^2(\alpha_{12}, \beta_{12}, \nu_{12})}B\left(\frac{1}{\alpha_1} + \frac{1}{\alpha_2} - \frac{1}{2\alpha_{12}}, \beta_1 + \beta_2 - 2\beta_{12}, \nu_1 + \nu_2 - 2\nu_{12}\right)}
$$

*,*

*with B defined as*

$$
B(\alpha, \beta, \nu) = \left(\frac{(\nu - \sqrt{\alpha \beta + \nu^2})}{2\beta}\right)^{\nu} \exp\left(\frac{\alpha \beta + \nu(-\nu - \sqrt{\alpha \beta + \nu^2})}{-\nu + \sqrt{\alpha \beta + \nu^2}}\right),
$$

*then* **SG**<sup>2</sup> *is positive semidefinite on any graph with Euclidean edges.*

As a second application to a full multivariate setting  $(p \geq 2)$ , consider the mappings  $\mathcal{M}_p$ ,  $\mathcal{C}_p$  and  $\mathcal{SG}_p$  defined on  $[0, +\infty)^{p \times p}$  by

<span id="page-21-3"></span>
$$
\mathcal{M}_p(\mathbf{D}) = \left[\sigma_{ij} \mathcal{M}_{\alpha_{ij}, \nu_{ij}} \left(D_{ij}^{\theta}\right)\right]_{i,j=1}^p, \tag{34}
$$

<span id="page-21-4"></span>
$$
\mathcal{C}_p(\mathbf{D}) = \left[\sigma_{ij} \mathcal{C}_{\alpha_{ij},\nu} \left(D_{ij}^{\theta}\right)\right]_{i,j=1}^p, \tag{35}
$$

<span id="page-21-5"></span>
$$
\boldsymbol{\mathcal{SG}}_{p}(\mathbf{D}) = \left[\sigma_{ij} \,\mathcal{SG}_{\alpha_{ij},\beta_{ij},\nu} \left(D_{ij}^{\theta}\right)\right]_{i,j=1}^{p},\tag{36}
$$

with  $[\sigma_{ij}]_{i,j=1}^p$ ,  $[\nu_{ij}]_{i,j=1}^p$ ,  $[\alpha_{ij}]_{i,j=1}^p$  and  $[\beta_{ij}]_{i,j=1}^p$  being real symmetric matrices,  $\nu$  a real number and  $\theta \in (0, 1]$ . Then the following statement holds.

<span id="page-21-0"></span>**Theorem 3.4.** Let  $\mathcal{M}_p$  defined by Equation [\(34\)](#page-21-3). If either

- **A.**  $[\nu_{ij}]_{i,j=1}^p$  and  $[\nu_{ij}\alpha_{ij}]_{i,j=1}^p$  are conditionally negative semidefinite and  $\left[\frac{\sigma_{ij}\nu_{ij}^{\nu_{ij}}\exp(-\nu_{ij})}{\Gamma(\nu_{ij})}\right]$  $\Gamma(\nu_{ij})$ *p i,j*=1 *is positive semidefinite or*
- **B.** *there exists*  $\beta > 0$  *such that*  $[\nu_{ij}]_{i,j=1}^p$  *and*  $[\alpha_{ij}^{-1} \beta \nu_{ij}]_{i,j=1}^p$  *are conditionally negative semidefinite and*  $\left[\sigma_{ij}(\beta \alpha_{ij})^{-\nu_{ij}} \exp(-\nu_{ij})\right]^p$ *i,j*=1 *is positive semidefinite,*

*then*  $\mathcal{M}_p$  *is positive semidefinite on any graph with Euclidean edges.* 

<span id="page-21-1"></span>**Theorem 3.5.** Let  $\mathcal{C}_p$  defined by Equation [\(35\)](#page-21-4) with  $\nu > 0$ . If  $[\beta_{ij}]_{i,j=1}^p$  is *conditionally negative semidefinite and*  $\left[\sigma_{ij}\beta_{ij}^{\nu}\right]_{i,j=1}^{\hat{p}}$  *is positive semidefinite, then*  $\mathcal{C}_p$  *is positive semidefinite on any graph with Euclidean edges.* 

<span id="page-21-2"></span>**Theorem 3.6.** *Let*  $\mathcal{SG}_p$  *defined by Equation [\(36\)](#page-21-5). If*  $[\alpha_{ij}^{-1}]_{i,j=1}^p$  *and*  $[\beta_{ij}]_{i,j=1}^p$ *i,j*=1 *are conditionally negative semidefinite and*  $\left[\sigma_{ij}(\alpha_{ij}\beta_{ij})^{\nu/2}/\mathcal{K}_{\nu}\left(\sqrt{\frac{\alpha_{ij}}{\beta_{ij}}}\right)\right]_{i,j=1}^p$ *is positive semidefinite, then* **SG***<sup>p</sup> is positive semidefinite on any graph with Euclidean edges.*

# <span id="page-22-0"></span>**4 Euclidean Trees**

Euclidean trees with a number *m* of leaves can be embedded on the *m*′ dimensional Euclidean space with  $m' := \lfloor m/2 \rfloor$  [\[Anderes et al.,](#page-27-0) [2020\]](#page-27-0) endowed with the  $\ell_1$  distance: for a positive integer  $m'$  and two points  $x, y \in$  $\mathbb{R}^{m'}$ , the  $\ell_1$  or Manhattan-city block distance  $d_M$  can be defined as  $d_M(x, y) =$  $\sum_{k=1}^{m'} |x_k - y_k|$ . According to this embedding, for every  $m' \geq 2$ , every matrixvalued covariance function depending on  $d_M$  can be used as an isotropic covariance function for a Euclidean tree The surprising fact is that, to the best of our knowledge, the literature has no models of multivariate covariance functions depending on such a metric. There is a fact that is even more surprising. Call  $\Phi_m^p$  the class of continuous mappings  $\mathbf{K} : [0, +\infty) \to \mathbb{R}^{p \times p}$ such that the composition  $\mathbf{K}(d_M(\cdot,\cdot))$  is positive semidefinite on a Euclidean tree with *m* leaves. A characterisation of this class is missing in the literature and we provide it below.

<span id="page-22-1"></span>**Proposition 10.** Let  $m, p$  be two positive integers. Let  $m' := \lfloor m/2 \rfloor$ . Let  $\mathbf{K} : [0, +\infty) \to \mathbb{R}^{p \times p}$  be continuous with  $\mathbf{K}(0) = \mathbf{1}_{p \times p}$ . Then, **K** belongs to *the class*  $\Phi_m^p$  *if and only if* 

<span id="page-22-3"></span>
$$
\mathbf{K}(t) = \int_0^{+\infty} \omega_{m'}(rt) \mathbf{F}(\mathrm{d}r), \qquad t \ge 0,
$$
 (37)

*where*  $\bf{F}$  *is a bounded symmetric matrix-valued measure such that*  $\bf{F}$ (d*r*) *is positive semidefinite for all r >* 0*, and where*

<span id="page-22-2"></span>
$$
\omega_{m'}(t) = \frac{\Gamma(m'/2)}{\sqrt{\pi}\Gamma((m'-1)/2)} \int_1^{+\infty} \Omega_{m'}(\sqrt{v}t)v^{-m'/2}(v-1)^{(m'-3)/2}dv,\tag{38}
$$

*with*  $\Omega_{m'}$  *being the characteristic function of a random vector that is uniformly distributed over the unit sphere*  $\mathbb{S}^{m'-1}$  *embedded in*  $\mathbb{R}^{m'}$ *.* 

Some comments are in order. For  $p = 1$ , the result has been proved by [Cambanis et al.](#page-30-1) [\[1983\]](#page-30-1). The following strict inclusion relations hold:

$$
\Phi_1^p \supset \Phi_2^p \supset \cdots \supset \bigcap_m \Phi_m^p =: \Phi_\infty^p.
$$

A convergence argument from [Schoenberg](#page-29-5) [\[1942\]](#page-29-5) applies *mutatis mutandis* to assert (no proof needed) that  $\mathbf{K} \in \Phi_{\infty}^p$  if and only if

$$
\mathbf{K}(t) = \int_0^{+\infty} \exp(-rt)\mathbf{F}(\mathrm{d}r), \qquad t \ge 0,
$$
 (39)

with **F** as in Proposition [10.](#page-22-1) Closed-form expressions for the inner kernel  $\omega_{m'}$  have been available thanks to [Gneiting](#page-30-2) [\[1998\]](#page-30-2). In particular, we have

$$
\omega_2(t) = -\frac{2}{\pi}\mathrm{si}(t)
$$
 and  $\omega_3(t) = \frac{1}{2}\left(\frac{\sin t}{t} + \cos t + t\,\mathrm{si}(t)\right)$ ,  $t \ge 0$ ,

where si denotes the sine integral function.

There exists a wealth of multivariate covariance models that depend on the Euclidean distance, denoted  $\|\cdot\|_m$ , in  $\mathbb{R}^m$ . Call  $\Psi_m^p$  the class of continuous mappings  $\mathbf{H} : [0, +\infty) \to \mathbb{R}^{p \times p}$  with  $\mathbf{H}(0) = \mathbf{1}_{p \times p}$  and  $\mathbf{H}(\|\cdot\|_m)$  being positive semidefinite in  $\mathbb{R}^m$ . The following result proves something extremely useful even for the scalar-case, that apparently was overlooked by [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0).

<span id="page-23-0"></span>**Proposition 11.** Let  $m, p$  be positive integers. Let  $m' := \lfloor m/2 \rfloor$ . Let **H** be *a* member of the class  $\Psi_{2m'-1}^p$ . Let the mapping **K** *be defined through* 

$$
\mathbf{K}(t) = I^{(m'-1)}\mathbf{H}(t), \qquad t \ge 0,
$$
\n
$$
(40)
$$

*where*  $I^{(m'-1)}$  *is the*  $(m'-1)$  *iterated application of the operator I, defined as* 

$$
(If)(t) := \frac{\int_t^{+\infty} f(u) \mathrm{d}u}{\int_0^{+\infty} f(u) \mathrm{d}u}.
$$

*Then,* **K** *belongs to the class*  $\Phi_m^p$ *.* 

Propositions [10](#page-22-1) and [11](#page-23-0) provide a recipe to build new members of the class  $\Phi_m^p$ . We start by univariate models, as described in Table [2,](#page-24-1) where we use the shortcuts  $\Psi_m$  and  $\Phi_m$  for  $\Psi_m^1$  and  $\Phi_m^1$ , respectively.

We can now use Proposition [11](#page-23-0) in concert with Table [2](#page-24-1) and the following Lemma, for which a proof is not provided as it follows the same path as Theorem [3.2.](#page-19-0)

<span id="page-23-1"></span>**Lemma 4.1.** *Let*  $m, p$  *be positive integers and*  $\phi : [0, +\infty) \to \mathbb{R}$  *be a member of the class*  $\Phi_m$ *. Let* **F** *be a matrix-valued measure as in Proposition [10.](#page-22-1) Then, the scale mixture*

$$
\mathbf{K}(t) = \int_0^{+\infty} \phi(rt) \mathbf{F}(\mathrm{d}r), \qquad t \ge 0,
$$
 (41)

*provides an element of the class*  $\Phi_m^p$ .

Parameter restriction	Member of $\Psi_{2m'-1}$	Member of $\Phi_m$
$\nu \geq m'$	$\psi_{\nu}(t)=(1-t)^{\nu}_{+}$	$\phi_{\nu}(t) = (1-t)^{\nu+m'-1}_{\perp}$
$\nu > m' + 1$		$\psi_{\nu}(t) = (1-t)^{\nu}_{+}(1+\nu t) \mid \phi_{\nu}(t) = \frac{1}{m'}(1-t)^{\nu+m'-1}_{+}(m'+\nu t)$

<span id="page-24-1"></span>Table 2: Elements of the class  $\Psi_{2m'-1}$  and corresponding element of the class  $\Phi_m$  after iterative application of the operator *I* as defined through Proposition [11.](#page-23-0) The first column provides the parametric restriction ensuring the corresponding element in the second column to be in  $\Psi_{2m'-1}$ .

Using the arguments in Theorem 1 of [Daley et al.](#page-30-3) [\[2015\]](#page-30-3) in concert with Lemma [4.1,](#page-23-1) one can prove that the multivariate model  $\mathbf{K}(t) = [K_{ij}(t)]_{i,j=1}^p$ with

$$
K_{ij}(t) = \sigma_i \sigma_{ij} \rho_{ij} \phi_{\nu_{ij}} \left(\frac{t}{b_{ij}}\right), \qquad t \ge 0,
$$

is a member of the class  $\Phi_m^p$  provided the constraints in Theorem 1 of [Daley](#page-30-3) [et al.](#page-30-3) [\[2015\]](#page-30-3) hold. Here,  $\phi_{\nu}$  can be any of the entries in Table [2.](#page-24-1)

We finish this section by providing a direct construction that is based on the kernel  $\omega_m$  as being defined through Equation [\(38\)](#page-22-2).

<span id="page-24-0"></span>**Proposition 12.** Let  $m, p$  be positive integers. Let  $m' := \lfloor m/2 \rfloor$ . Let  $[\rho_{ij}]_{i,j=1}^p$ ,  $[b_{ij}]_{i,j=1}^p$  *and*  $[\nu_{ij}]_{i,j=1}^p$  *be real symmetric matrices such that*  $b_{ij} > 0$ *and*  $\nu_{ij} > 2m' - 1$  *for*  $i, j = 1, \ldots, p$ *. For*  $r > 0$ *, define*  $\mathbf{A}(r)$  *with entries* 

<span id="page-24-2"></span>
$$
A_{ij}(r) = \frac{\rho_{ij} \Gamma(\frac{\nu_{ij}}{2})}{\Gamma(\frac{\nu_{ij}}{2} - m' + \frac{1}{2}) \Gamma(m' - \frac{1}{2})} \left(1 - b_{ij}^2 r^2\right)_+^{\frac{\nu_{ij}}{2} - m' - \frac{1}{2}}, \quad i, j = 1, \dots, p.
$$
\n(42)

*Then, the mapping*  $\mathbf{K} : [0, +\infty) \to \mathbb{R}^{p \times p}$  *with entries* 

<span id="page-24-3"></span>
$$
K_{ij}(x) = \frac{\rho_{ij}}{b_{ij}^{2m'-1}} \,\omega_{\nu_{ij}}\left(\frac{x}{b_{ij}}\right), \qquad x \ge 0, \quad i, j = 1, \dots, p,
$$
 (43)

*belongs to*  $\Phi_m^p$  *provided the matrix*  $\mathbf{A}(r)$  *as defined in* [\(42\)](#page-24-2) *is positive semidefinite for any*  $r > 0$ .

Sufficient conditions ensuring  $A(r)$  to be positive semidefinite for every fixed  $r \geq 0$  are provided by [Emery and Porcu](#page-30-4) [\[2023,](#page-30-4) Proposition 1]. The kernel [\(43\)](#page-24-3) is especially flexible as it can be used to generate new families of multivariate kernels by using the scale mixture approaches highlighted above.

<span id="page-25-0"></span>Figure 3: Marginal and cross covariance functions in terms of the resistance metric, over a tree with  $m = 4$  leaves, measured from a reference location (black circle).

<span id="page-25-1"></span>Figure 4: Realisation of a positively correlated bivariate random field on a tree with  $m = 4$  leaves, with a covariance function of Askey type.

We conclude this section with an illustration to the bivariate setting  $(p =$ 2) for a Euclidean tree with  $m = 4$  leaves. The entries of the covariance function are given by  $K_{11}(d_R(u, v)) = (1 - d_R(u, v)/4)^3_+, K_{22}(d_R(u, v)) =$  $(1-d_R(u, v))^3_+$ , and  $K_{12}(d_R(u, v)) = 0.6 \times (1-d_R(u, v)/2.5)^3_+$ , for all  $u, v \in \mathcal{G}$ . Here, the collocated correlation coefficient between the two random field components is 0*.*6.

Figure [3](#page-25-0) displays the decay of this covariance function in terms of the resistance metric measured from a reference location. It is evident that the first component of the random field has a larger correlation range, as reflected in the left panel: high (low) values of this variable tend to be surrounded by a wider extent of high (low) values. Figure [4](#page-25-1) shows a realisation of a bivariate Gaussian random field over 750 sites on the tree. The Cholesky decomposition of the covariance matrix was used to perform this simulation.

### <span id="page-26-0"></span>**5 Conclusions**

This paper has shown the intricacies related to the construction to multivariate kernels over generalised frameworks that are represented through a broad class of metric graphs. One might argue that other classes of metric graphs are preferable in certain situations. However, to our knowledge, the only alternative has been proposed by [Bolin et al.](#page-27-7) [\[2022\]](#page-27-7) and coupled with the substantially different approach of stochastic partial differential equations. It is extremely challenging to attempt for a comparison between these approaches. One important advantage provided by [Bolin et al.](#page-27-7) [\[2022\]](#page-27-7) for scalar-valued random fields is that an example of a once mean-square differentiable random field is provided. Yet, this is limited to a specific example, while the approach by [Anderes et al.](#page-27-0)  $[2020]$  — hence, our approach — allows to embrace a wealth of examples. Being the first contribution related to vector-valued random fields on metric graphs, this paper does not have a competitor to compare with.

A next intuitive step to this research is represented by vector-valued space-time random fields. The machinery provided in this paper allows for a fairly general building block to start with. Space-time models might also be the building blocks to nonstationary models for networks.

The impact of this research is apparent. The works by [Baddeley et al.](#page-29-3) [\[2017\]](#page-29-3) and [Moradi and Mateu](#page-27-1) [\[2020\]](#page-27-1) are a clear indication of the importance of this work to modelling point processes over networks. There is a fervent activity related to vector-valued processes in the machine learning community, with the reader referred to [Borovitskiy et al.](#page-28-3) [\[2022\]](#page-28-3) for details.

### **Acknowledgements**

The authors are grateful to Valeria Simoncini for her support regarding the solutions of matrix quadratic equations. X. Emery acknowledges the support of the National Agency for Research and Development of Chile, through grants ANID Fondecyt 1210050 and ANID PIA AFB230001. Emilio Porcu is grateful to Horst Simon for enlightening discussion about multivariate isometric embeddings.

### <span id="page-32-0"></span>**A Technical Results and Proofs**

This part of the Appendix contains proofs and technical results. To help the reader, Figure [1](#page-5-0) provides the road-map of the main results of this manuscript.

<span id="page-32-1"></span>**Lemma A.1.** *Let*  $\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D}$  *be*  $n \times n$  *matrices and let*  $p \in \{1, 2, \ldots\}$ *. Then* 

$$
\mathcal{M}_p \begin{pmatrix} \mathbf{A} \\ \mathbf{B} \end{pmatrix} \mathcal{M}_p \begin{pmatrix} \mathbf{C} \\ \mathbf{D} \end{pmatrix} = \mathcal{M}_p \begin{pmatrix} \mathbf{AC} + (p-1)\mathbf{BD} \\ \mathbf{AD} + \mathbf{BC} + (p-2)\mathbf{BD} \end{pmatrix}.
$$
 (44)

*Proof of Lemma [A.1.](#page-32-1)* By the standard properties of the Kronecker product,

$$
(\mathbf{I}_p \otimes \mathbf{A} + (\mathbf{1}_{p \times p} - \mathbf{I}_p) \otimes \mathbf{B}) (\mathbf{I}_p \otimes \mathbf{C} + (\mathbf{1}_{p \times p} - \mathbf{I}_p) \otimes \mathbf{D}) =
$$
  
\n
$$
= (\mathbf{I}_p \otimes \mathbf{A})(\mathbf{I}_p \otimes \mathbf{C}) + (\mathbf{I}_p \otimes \mathbf{A}) ((\mathbf{1}_{p \times p} - \mathbf{I}_p) \otimes \mathbf{D})
$$
  
\n
$$
+ ((\mathbf{1}_{p \times p} - \mathbf{I}_p) \otimes \mathbf{B}) (\mathbf{I}_p \otimes \mathbf{C}) + ((\mathbf{1}_{p \times p} - \mathbf{I}_p) \otimes \mathbf{B}) ((\mathbf{1}_{p \times p} - \mathbf{I}_p) \otimes \mathbf{D})
$$
  
\n
$$
= (\mathbf{I}_p \mathbf{I}_p) \otimes (\mathbf{A}\mathbf{C}) + (\mathbf{I}_p (\mathbf{1}_{p \times p} - \mathbf{I}_p)) \otimes (\mathbf{A}\mathbf{D})
$$
  
\n
$$
+ ((\mathbf{1}_{p \times p} - \mathbf{I}_p) \mathbf{I}_p) \otimes (\mathbf{B}\mathbf{C}) + ((\mathbf{1}_{p \times p} - \mathbf{I}_p)(\mathbf{1}_{p \times p} - \mathbf{I}_p)) \otimes (\mathbf{B}\mathbf{D})
$$
  
\n
$$
= \mathbf{I}_p \otimes (\mathbf{A}\mathbf{C}) + (\mathbf{1}_{p \times p} - \mathbf{I}_p) \otimes (\mathbf{A}\mathbf{D} + \mathbf{B}\mathbf{C}) + (p\mathbf{1}_{p \times p} - 2 \cdot \mathbf{1}_{p \times p} + \mathbf{I}_p) \otimes (\mathbf{B}\mathbf{D})
$$
  
\n
$$
= \mathbf{I}_p \otimes (\mathbf{A}\mathbf{C}) + (\mathbf{1}_{p \times p} - \mathbf{I}_p) \otimes (\mathbf{A}\mathbf{D} + \mathbf{B}\mathbf{C})
$$
  
\n
$$
+ ((p-2)(\mathbf{1}_{p \times p} - \mathbf{I}_p) + (p-1
$$

 $\Box$ 

*Proof of Proposition [1.](#page-8-0)* Throughout this proof, we assume that  $\mathbf{L} \in \mathbb{R}^{n \times n}$ ,  $A \in \mathbb{R}^{n_1 \times n_1}$  and  $\mathbf{C} \in \mathbb{R}^{n_2 \times n_2}$ , with  $n_1, n_2 > 0$  and  $n = n_1 + n_2$ .

- 1. Assume  $\mathbf{B} = 0$ . Then  $n 1 = \text{rank}(\mathbf{L}) = \text{rank}(\mathbf{A}) + \text{rank}(\mathbf{C})$ . But since  $L1_n = 0$ , it follows that  $A1_{n_1} = 0$  and  $C1_{n_2} = 0$ . This implies that rank( $\mathbf{A}$ )  $\leq n_1 - 1$  and rank( $\mathbf{C}$ )  $\leq n_2 - 1$ . Contradiction.
- 2. We will show only that **C** strictly positive definite, as the proof for the other case relies on the same argument. Since **C** is a principal submatrix of **L**, it is positive semidefinite. As a consequence, it is sufficient to show that it is invertible. Assume, by contradiction, that **C** is singular. This is equivalent to assume that  $\exists y \neq 0$  such that

 $\mathbf{C}\mathbf{y} = \mathbf{0}$ . Since **L** is positive semidefinite we have, for each  $\mathbf{x} \in \mathbb{R}^{n_1}$ and for each  $\gamma \in \mathbb{R}$ :

$$
0 \leq \begin{bmatrix} x \\ \gamma y \end{bmatrix}^\top \begin{bmatrix} A & B \\ B^\top & C \end{bmatrix} \begin{bmatrix} x \\ \gamma y \end{bmatrix} \\
= x^\top Ax + x^\top B (\gamma y) + (\gamma y)^\top B^\top x + (\gamma y)^\top C (\gamma y) = x^\top Ax + 2\gamma x^\top By.
$$

If  $\mathbf{x}^\top \mathbf{B} \mathbf{y} \neq 0$ , we can find a suitable  $\gamma$  that contradicts the previous inequality. Hence  $\boldsymbol{x}^\top \mathbf{B} \boldsymbol{y} = 0$  and therefore, being  $\boldsymbol{x}$  arbitrary,  $\mathbf{B} \boldsymbol{y} = \mathbf{0}$ . Consider now the vector  $\boldsymbol{z} := (0, ..., 0, \boldsymbol{y}^{\top})^{\top}$ : we have  $\boldsymbol{L}\boldsymbol{z} = \boldsymbol{0}$ , but clearly z does not lie in the null space of **L**, which is  $\{\lambda \mathbf{1}_n : \lambda \in \mathbb{R}\}.$ Contradiction.

3. Clearly **L***/***C** is symmetric. Furthermore, the Guttman rank addi-tivity formula [\[Zhang,](#page-30-5) [2005,](#page-30-5) Equation 0.9.2] states that  $rank(L)$  = rank( $\mathbf{C}$ )+rank( $\mathbf{L}/\mathbf{C}$ ). Here we have rank( $\mathbf{L}$ ) = *n*-1 and rank( $\mathbf{C}$ ) = *n*<sub>2</sub>, as a consequence rank $(L/C) = n_1 - 1$ . Furthermore, from [Zhang](#page-30-5) [\[2005,](#page-30-5) Theorem 1.12], being **C** strictly positive definite and *L* positive semidefinite, we have that  $L/C$  is positive semidefinite as well. The last thing that is left to be shown is that the null eigenvector of  $\mathbf{L}/\mathbf{C}$  is  $\mathbf{1}_{n_1}$ . Since  $\mathbf{1}_n$  is the null eigenvector of  $\mathbf{L}$ , we get

$$
\begin{bmatrix} A & B \end{bmatrix} \mathbf{1}_n = \mathbf{0} \quad \text{and} \quad \begin{bmatrix} B^\top & C \end{bmatrix} \mathbf{1}_n = \mathbf{0},
$$

videlicet  $\mathbf{A1}_{n_1} + \mathbf{B1}_{n_2} = \mathbf{0}$  and  $\mathbf{B}^\top \mathbf{1}_{n_1} + \mathbf{C1}_{n_2} = \mathbf{0}$ . Using these relations, the following chain of equivalences concludes the proof:

$$
(\mathbf{A} - \mathbf{B}\mathbf{C}^{-1}\mathbf{B}^{\top})\mathbf{1}_{n_1} = \mathbf{0} \iff \mathbf{A}\mathbf{1}_{n_1} = \mathbf{B}\mathbf{C}^{-1}\mathbf{B}^{\top}\mathbf{1}_{n_1}
$$
  

$$
\iff -\mathbf{B}\mathbf{1}_{n_2} = \mathbf{B}\mathbf{C}^{-1}(-\mathbf{C}\mathbf{1}_{n_2}) \iff -\mathbf{B}\mathbf{1}_{n_2} = -\mathbf{B}\mathbf{1}_{n_2}.
$$

4. Consider the eigendecomposition of **L**:

<span id="page-33-0"></span>
$$
\mathbf{L} = \mathbf{W} \begin{bmatrix} \Delta & 0 \\ 0 & 0 \end{bmatrix} \mathbf{W}^{\top}, \tag{45}
$$

with  $\Delta$  a  $(n-1) \times (n-1)$  diagonal matrix with positive diagonal entries. Since **W** is an orthogonal matrix, we have

<span id="page-33-1"></span>
$$
\mathbf{L}^{-} = \left(\mathbf{W} \begin{bmatrix} \Delta & 0 \\ 0 & 0 \end{bmatrix} \mathbf{W}^{\top}\right)^{-} = (\mathbf{W}^{\top})^{-} \begin{bmatrix} \Delta & 0 \\ 0 & 0 \end{bmatrix}^{\top} \mathbf{W}^{-} = \mathbf{W} \begin{bmatrix} \Delta^{-1} & 0 \\ 0 & 0 \end{bmatrix} \mathbf{W}^{\top}.
$$
\n(46)

Therefore **L**<sup>−</sup> is symmetric, is positive semidefinite and with exactly one null eigenvalue, corresponding to the same null-space eigenvector of **L**.

 $\Box$ 

<span id="page-34-0"></span>**Lemma A.2.** *Let* **L** *be an*  $n \times n$  *quasi-Laplacian matrix and*  $\Sigma = L^{-}$ *. Let*  $\Sigma =: \mathbf{W}\Lambda \mathbf{W}^{\top}$  *be the eigendecomposition of*  $\Sigma$ *, with*  $\Lambda = \text{diag} \left( \begin{bmatrix} \lambda_1, \ldots, \lambda_n \end{bmatrix} \right)$  $\alpha$  *and*  $\lambda_1 \geq \cdots \geq \lambda_{n-1} > \lambda_n = 0$ . Let **Q** be defined as in Subsection [3.1.](#page-13-1) Then, *the eigenvalues*  $\lambda_n(\mathbf{Q}) < \lambda_1(\mathbf{Q}) \leq \cdots \leq \lambda_{n-1}(\mathbf{Q})$  of **Q** are:

$$
\lambda_i(\mathbf{Q}) = \begin{cases} \frac{1}{2} \left( \lambda_i^{-1} + \sqrt{\lambda_i^{-2} - 2\alpha (p-2)\lambda_i^{-1} + \alpha^2 p^2} + \alpha (p-2) \right) & i \neq n \\ \alpha (p-1) & i = n. \end{cases}
$$

*In particular the smallest eigenvalue of*  $\mathbf{Q}$ *,*  $\lambda_n(\mathbf{Q})$ *, is strictly positive, thus*  $\mathbf{Q}$ *is strictly positive definite. In addition,*  $\mathbf{Q1}_n = \alpha(p-1)\mathbf{1}_n$ *.* 

*Proof of Lemma [A.2.](#page-34-0)* Recall the eigendecomposition of matrix **Q** given in Equation [\(19\)](#page-14-1): it is clear that the eigenvalues of **Q** are the elements on the diagonal of the matrix

$$
\frac{1}{2}\left(\mathbf{\Lambda}^- + \sqrt{(\mathbf{\Lambda}^-)^2 - 2\alpha(p-2)\mathbf{\Lambda}^- + \alpha^2p^2\mathbf{I}_n} + \alpha(p-2)\mathbf{I}_n\right),\,
$$

which are  $\{f(\lambda^-) : \lambda \in \{\lambda_1, \ldots, \lambda_n\}\}\$ , where  $\lambda_1, \ldots, \lambda_n$  are the diagonal entries of  $\Lambda$  (positive, except for  $\lambda_n$  that is null) and

$$
f(\lambda^-) := \frac{1}{2} \left( \lambda^- + \sqrt{(\lambda^-)^2 - 2\alpha (p-2)\lambda^- + \alpha^2 p^2} + \alpha (p-2) \right).
$$

Here, we recall that, for a scalar  $\lambda \in \mathbb{R}$ ,  $\lambda^- := \lambda^{-1}$  if  $\lambda \neq 0$  and  $\lambda^- := 0$  if  $\lambda = 0$ . It is straightforward to show that  $\lambda^- \mapsto f(\lambda^-)$  is a strictly increasing function on  $\lambda^- \geq 0$ . As a consequence, since  $\lambda \mapsto \lambda^-$  is strictly decreasing on  $\lambda > 0, \lambda \mapsto f(\lambda^-)$  is strictly decreasing on  $\lambda > 0$ . Therefore,  $\lambda_1 \geq \cdots \geq \lambda_{n-1}$ are mapped in  $\lambda_1(\mathbf{Q}) = f(\lambda_1^{-1}) \leq \cdots \leq \lambda_{n-1}(\mathbf{Q}) = f(\lambda_{n-1}^{-1})$ . For the case *λ*<sub>*n*</sub> = 0, we have  $λ_n$ (**Q**) =  $f(λ^-_n) = f(0) = \frac{1}{2} (αp + α(p - 2)) = α(p - 1)$ . In addition, since  $\lambda_n = 0 < \lambda_1(\mathbf{Q})$ , we have  $\alpha(p-1) = \lambda_n(\mathbf{Q}) < \lambda_1(\mathbf{Q})$ .

Finally, to show that  $\mathbf{Q1}_n = \alpha (p-1)\mathbf{1}_n$ , it is sufficient to notice from the eigendecomposition of **Q** given in Equation  $(19)$  that  $\mathbf{1}_n$ , being (proportional to) the last column of **W**, is an eigenvector of **Q**. And by the above result it is clear that the corresponding eigenvalue is  $\lambda_n(\mathbf{Q}) = \alpha(p-1)$ . This concludes the proof.  $\Box$ 

<span id="page-35-0"></span>**Lemma A.3.** *Let* **L** *be an*  $n \times n$  *quasi-Laplacian matrix,*  $\Sigma = L^{-}$  *and*  $\alpha > 0$ *. Furthermore, let* **Q** *and* **X** *as defined in Subsection [3.1.](#page-13-1) Then the following holds:*

*1.* Σ*,* **L***,* **Q** *and* **X** *commute;*

2. 
$$
\Sigma L = L\Sigma = I_n - \frac{1}{n}I_{n\times n}
$$
;

3. 
$$
\mathbf{Q}^2 - \alpha^2 (p-1) \mathbf{I}_n - \mathbf{Q} \mathbf{L} - \alpha (p-2) \mathbf{Q} + \alpha (p-2) \mathbf{L} = \mathbf{0};
$$

4. 
$$
\Sigma \mathbf{Q}^2 - \alpha^2 (p-1) \Sigma - \mathbf{Q} - \alpha (p-2) \Sigma \mathbf{Q} + \alpha (p-2) \mathbf{I}_n + \frac{\alpha}{n} \mathbf{1}_{n \times n} = \mathbf{0}.
$$

*Proof of Lemma [A.3.](#page-35-0)* 1. It is sufficient to notice that all the matrices share the same eigenvector matrix **W**, *i.e.* for any  $A, B \in \{\Sigma, L, Q, X\}$ , there are two diagonal matrices  $\Lambda_A$ ,  $\Lambda_B$  such that  $A = W \Lambda_A W^{\top}$  and  $\mathbf{B} = \mathbf{W} \mathbf{\Lambda}_{\mathbf{B}} \mathbf{W}^\top$ . Therefore

$$
AB = W\Lambda_A W^{\top} W\Lambda_B W^{\top} = W\Lambda_A \Lambda_B W^{\top} = W\Lambda_B \Lambda_A W^{\top}
$$

$$
= W\Lambda_B W^{\top} W\Lambda_A W^{\top} = BA.
$$

2. By exploiting the diagonalisations  $\Sigma = W\Lambda W^{\top}$  (Lemma [A.2\)](#page-34-0) and  $\mathbf{L} = \mathbf{W} \mathbf{\Lambda}^- \mathbf{W}^{\top}$  (Eqs. [\(45\)](#page-33-0) and [\(46\)](#page-33-1)), we get:

$$
\Sigma L = W \Lambda \Lambda^{-} W^{\top} = W (I_n - J_n) W^{\top} = I_n - W J_n W^{\top}.
$$

Given that **L** is a quasi-Laplacian matrix, its eigenvector matrix **W** can be written as

<span id="page-35-1"></span>
$$
\mathbf{W} = \begin{bmatrix} \mathbf{U} & c\mathbf{1}_n \end{bmatrix},
$$

where  $\mathbf{U} \in \mathbb{R}^{n \times (n-1)}$  and  $nc^2 = 1$ . Therefore

$$
\mathbf{W}\mathbf{J}_n\mathbf{W}^\top = \begin{bmatrix} \mathbf{U} & c\mathbf{1}_n \end{bmatrix} \begin{bmatrix} \mathbf{0}_{(n-1)\times(n-1)} & \mathbf{0}_{(n-1)\times1} \\ \mathbf{0}_{1\times(n-1)} & 1 \end{bmatrix} \begin{bmatrix} \mathbf{U}^\top \\ c\mathbf{1}_n \end{bmatrix} = \frac{1}{n} \mathbf{1}_n \mathbf{1}_n \mathbf{1}_n \tag{47}
$$

and this concludes the proof.

3. From the definition [\(18\)](#page-14-3) of **Q**, one has:

$$
2\mathbf{Q} - \mathbf{L} - \alpha(p-2)\mathbf{I}_n = \sqrt{\mathbf{L}^2 - 2\alpha(p-2)\mathbf{L} + \alpha^2 p^2 \mathbf{I}_n}.
$$

Now, taking the square of both sides (recall that **Q** and **L** commute):

$$
4\mathbf{Q}^2 + \mathbf{L}^2 + \alpha^2(p-2)^2 \mathbf{I}_n - 4\mathbf{Q}\mathbf{L} - 4\alpha(p-2)\mathbf{Q} + 2\alpha(p-2)\mathbf{L}
$$
  
= 
$$
\mathbf{L}^2 - 2\alpha(p-2)\mathbf{L} + \alpha^2 p^2 \mathbf{I}_n.
$$

By grouping the common terms and dividing everything by 4 we get the desired result.

4. To show the second assertion, it is sufficient to multiply the first equation by  $\Sigma = L^{-}$ :

$$
\Sigma \mathbf{Q}^2 - \alpha^2 (p-1) \Sigma - \mathbf{Q} (\Sigma \mathbf{L}) - \alpha (p-2) \Sigma \mathbf{Q} + \alpha (p-2) (\Sigma \mathbf{L}) = \mathbf{0}
$$
  
\n
$$
\Sigma \mathbf{Q}^2 - \alpha^2 (p-1) \Sigma - \mathbf{Q} + \frac{1}{n} \lambda_n (\mathbf{Q}) \mathbf{1}_{n \times n} - \alpha (p-2) \Sigma \mathbf{Q} + \alpha (p-2) \mathbf{I}_n
$$
  
\n
$$
-\frac{\alpha (p-2)}{n} \mathbf{1}_{n \times n} = \mathbf{0},
$$

where we have used  $\Sigma L = I_n - \frac{1}{n}$  $\frac{1}{n}$ **1**<sub>*n*×*n*</sub> and **Q1**<sub>*n*</sub> = *λ*<sub>*n*</sub>(**Q**)**1**<sub>*n*</sub> = *α*(*p*−1)**1***<sub><i>n*</sub>  $(Lemma A.2).$  $(Lemma A.2).$  $(Lemma A.2).$ 

<span id="page-36-0"></span>**Lemma A.4.** *Let*  $X, Y \in \mathbb{R}^{n \times n}$  *be symmetric matrices. For*  $i \in \{1, \ldots, n\}$ *, let*  $\lambda_i(\mathbf{X})$  *and*  $\lambda_i(\mathbf{Y})$  *denote the i*<sup>th</sup> *eigenvalues of* **X** *and* **Y***, respectively. Let*  $c \in \mathbb{R}$  *such that*  $\lambda_i(\mathbf{X}) \geq c$  *and*  $\lambda_i(\mathbf{Y}) \geq -c$  *for all*  $i \in \{1, \ldots, n\}$ *. Then*  $X + Y$  *is positive semidefinite.* 

*Proof of Lemma [A.4.](#page-36-0)* Let  $X = W_1 \Delta_1 W_1^{\top}$  and  $Y = W_2 \Delta_2 W_2^{\top}$  be the eigendecompositions of **X** and **Y** and let  $v \in \mathbb{R}^n$ . In the following lines, we have  $\text{defined } \boldsymbol{a} := \mathbf{W}_1^\top \boldsymbol{v} \text{ and } \boldsymbol{b} := \mathbf{W}_2^\top \boldsymbol{v}.$ 

$$
\mathbf{v}^\top (\mathbf{X} + \mathbf{Y}) \mathbf{v} = \mathbf{v}^\top \mathbf{W}_1 \Delta_1 \mathbf{W}_1^\top \mathbf{v} + \mathbf{v} \mathbf{W}_2 \Delta_2 \mathbf{W}_2^\top \mathbf{v} = \mathbf{a}^\top \Delta_1 \mathbf{a} + \mathbf{b}^\top \Delta_2 \mathbf{b}
$$
  
= 
$$
\sum_{i=1}^n \lambda_i (\mathbf{X}) a_i^2 + \sum_{i=1}^n \lambda_i (\mathbf{Y}) b_i^2 \ge c \sum_{i=1}^n a_i^2 - c \sum_{i=1}^n b_i^2
$$
  
=  $c(\mathbf{a}^\top \mathbf{a} - \mathbf{b}^\top \mathbf{b}) = c(\mathbf{v}^\top \mathbf{v} - \mathbf{v}^\top \mathbf{v}) = 0.$ 

Videlicet,  $X + Y$  is positive semidefinite.

<span id="page-36-1"></span>**Lemma A.5.** *Let* **L** *an*  $n \times n$  *Laplacian matrix, let*  $\Sigma := L^-$  *its Moore-Penrose inverse and let*  $\alpha > 0$ *. Let*  $\Theta$ *,* **Q***,* **X***,*  $k_1$ *,*  $k_2$ *,*  $\tilde{\Sigma}$  *and*  $\tilde{\mathbf{X}}$  *as described in Subsection [3.1.](#page-13-1) Finally let:*

$$
\tilde{\mathbf{K}} := \mathcal{M}_p \begin{pmatrix} \tilde{\Sigma} \\ \tilde{\mathbf{X}} \end{pmatrix} . \tag{48}
$$

 $\Box$ 

 $\Box$ 

*Then*  $\tilde{\mathbf{K}} = \mathbf{\Theta}^-$ .

*Proof of Lemma [A.5.](#page-36-1)* In order to show that  $\tilde{\mathbf{K}} = \mathbf{\Theta}^-$ , by definition of the Moore-Penrose inverse, we need to prove

- 1.  $\Theta \tilde{K}$  and  $\tilde{K} \Theta$  are symmetric,
- 2.  $\Theta \tilde{K} \Theta = \Theta$ ,
- 3.  $\tilde{\mathbf{K}}\boldsymbol{\Theta}\tilde{\mathbf{K}} = \tilde{\mathbf{K}}.$

To show symmetry, recall from Lemma [A.3](#page-35-0) that all the matrices  $Q$ *,*  $\alpha$ **I**<sub>*n*</sub>,  $\Sigma$ *,* **X***,* **1**<sub>*n*×*n*</sub> commute. As a consequence,  $\forall A, B, C, D \in \{Q, \alpha I_n, \Sigma, X, 1_{n \times n}\}\)$ , it holds  $(Lemma A.1):$  $(Lemma A.1):$  $(Lemma A.1):$ 

$$
\mathcal{M}_p\begin{pmatrix}\n\mathbf{A} \\
\mathbf{B}\n\end{pmatrix}\n\mathcal{M}_p\begin{pmatrix}\n\mathbf{C} \\
\mathbf{D}\n\end{pmatrix} = \mathcal{M}_p\begin{pmatrix}\n\mathbf{A}\mathbf{C} + (p-1)\mathbf{B}\mathbf{D} \\
\mathbf{A}\mathbf{D} + \mathbf{B}\mathbf{C} + (p-2)\mathbf{B}\mathbf{D}\n\end{pmatrix}
$$
\n
$$
= \mathcal{M}_p\begin{pmatrix}\n\mathbf{CA} + (p-1)\mathbf{D}\mathbf{B} \\
\mathbf{DA} + \mathbf{CB} + (p-2)\mathbf{D}\mathbf{B}\n\end{pmatrix} = \mathcal{M}_p\begin{pmatrix}\n\mathbf{C} \\
\mathbf{D}\n\end{pmatrix}\mathcal{M}_p\begin{pmatrix}\n\mathbf{A} \\
\mathbf{B}\n\end{pmatrix}.
$$

 $\text{Im addition, } \mathcal{M}_p(\mathbf{A}, \mathbf{B})^\top = \mathcal{M}_p(\mathbf{A}^\top, \mathbf{B}^\top) = \mathcal{M}_p(\mathbf{A}, \mathbf{B})$ , as  $\mathbf{A}, \mathbf{B}$  are symmetric. Therefore,

$$
\begin{split}\n&\left(\mathbf{\Theta}\tilde{\mathbf{K}}\right)^{\top} = \tilde{\mathbf{K}}^{\top}\mathbf{\Theta}^{\top} = \mathcal{M}_{p} \begin{pmatrix} \Sigma + k_{1}\mathbf{1}_{n\times n} \\ \mathbf{X} + k_{2}\mathbf{1}_{n\times n} \end{pmatrix}^{\top} \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} \\ -\alpha \mathbf{I}_{n} \end{pmatrix}^{\top} \\
&= \mathcal{M}_{p} \begin{pmatrix} \Sigma^{\top} + k_{1}\mathbf{1}_{n\times n} \\ \mathbf{X}^{\top} + k_{2}\mathbf{1}_{n\times n} \end{pmatrix} \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q}^{\top} \\ -\alpha \mathbf{I}_{n} \end{pmatrix} \\
&= \mathcal{M}_{p} \begin{pmatrix} \Sigma \\ \mathbf{X} \end{pmatrix} \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} \\ -\alpha \mathbf{I}_{n} \end{pmatrix} + \mathcal{M}_{p} \begin{pmatrix} k_{1}\mathbf{1}_{n\times n} \\ k_{2}\mathbf{1}_{n\times n} \end{pmatrix} \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} \\ -\alpha \mathbf{I}_{n} \end{pmatrix} \\
&= \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} \\ -\alpha \mathbf{I}_{n} \end{pmatrix} \mathcal{M}_{p} \begin{pmatrix} \Sigma \\ \mathbf{X} \end{pmatrix} + \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} \\ -\alpha \mathbf{I}_{n} \end{pmatrix} \mathcal{M}_{p} \begin{pmatrix} k_{1}\mathbf{1}_{n\times n} \\ k_{2}\mathbf{1}_{n\times n} \end{pmatrix} \\
&= \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} \\ -\alpha \mathbf{I}_{n} \end{pmatrix} \mathcal{M}_{p} \begin{pmatrix} \Sigma + k_{1}\mathbf{1}_{n\times n} \\ \mathbf{X} + k_{2}\mathbf{1}_{n\times n} \end{pmatrix} = \mathbf{\Theta}\tilde{\mathbf{K}}.\n\end{split}
$$

The same arguments show that  $(\tilde{\mathbf{K}}\mathbf{\Theta})^{\top} = \tilde{\mathbf{K}}\mathbf{\Theta}$ . To prove the other two relations, we start with following equalities. In the next lines, we used Lemmas [A.1,](#page-32-1) [A.2](#page-34-0) and [A.3.](#page-35-0)

$$
\begin{split}\n\Theta \mathbf{K} &= \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} \\ -\alpha \mathbf{I}_{n} \end{pmatrix} \mathcal{M}_{p} \begin{pmatrix} \Sigma \\ \mathbf{X} \end{pmatrix} = \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} \Sigma - \alpha(p-1) \mathbf{X} \\ \mathbf{Q} \mathbf{X} - \alpha \Sigma - \alpha(p-2) \mathbf{X} \end{pmatrix} \\
&= \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} \Sigma - \alpha(p-1) \frac{1}{-\alpha(p-1)} (\mathbf{I}_{n} - \Sigma \mathbf{Q}) \\ \frac{1}{-\alpha(p-1)} (\mathbf{Q} - \Sigma \mathbf{Q}^{2}) - \alpha \Sigma - \alpha(p-2) \mathbf{X} \end{pmatrix} = \mathcal{M}_{p} \begin{pmatrix} \mathbf{I}_{n} \\ -\frac{1}{n(p-1)} \mathbf{I}_{n \times n} \end{pmatrix} \\
\Theta \mathbf{K} \Theta &= \mathcal{M}_{p} \begin{pmatrix} \mathbf{I}_{n} \\ -\frac{1}{n(p-1)} \mathbf{I}_{n \times n} \end{pmatrix} \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} \\ -\alpha \mathbf{I}_{n} \end{pmatrix} \\
&= \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} + \alpha(p-1) \frac{1}{n(p-1)} \mathbf{I}_{n \times n} \\ -\alpha \mathbf{I}_{n} - \frac{1}{n(p-1)} \mathbf{Q} \mathbf{1}_{n \times n} + \alpha(p-2) \frac{1}{n(p-1)} \mathbf{1}_{n \times n} \end{pmatrix} \\
&= \mathcal{M}_{p} \begin{pmatrix} k_{1} \mathbf{1}_{n \times n} \\ k_{2} \mathbf{1}_{n \times n} \end{pmatrix} = \mathcal{M}_{p} \begin{pmatrix} k_{1} \mathbf{Q} \mathbf{1}_{n \times n} - \alpha(p-1) k_{2} \mathbf{1}_{n \times n} \\ k_{2} \mathbf{Q} \mathbf{1}_{n \times n} - \alpha k_{1} \mathbf{1}_{n \times n} - \alpha k_{2}(p-2) \mathbf{1}_{n \times n} \end{pmatrix} \\
&= \mathcal{M}_{p} \begin{pmatrix} k_{1} \math
$$

As a consequence:

$$
\begin{split}\n\boldsymbol{\Theta}\tilde{\mathbf{K}}\boldsymbol{\Theta} &= \boldsymbol{\Theta}\left(\mathbf{K} + \mathcal{M}_{p} \begin{pmatrix} k_{1}\mathbf{1}_{n\times n} \\ k_{2}\mathbf{1}_{n\times n} \end{pmatrix}\right)\boldsymbol{\Theta} \\
&= \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} + \frac{\alpha}{n}\mathbf{1}_{n\times n} \\ -\alpha\mathbf{I}_{n} - \frac{\alpha}{n(p-1)}\mathbf{1}_{n\times n} \end{pmatrix} + \mathcal{M}_{p} \begin{pmatrix} \alpha^{2}p(p-1)(k_{1} - k_{2})\mathbf{1}_{n\times n} \\ -\alpha^{2}p(k_{1} - k_{2})\mathbf{1}_{n\times n} \end{pmatrix} \\
&= \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} + \frac{\alpha}{n}\mathbf{1}_{n\times n} + \alpha^{2}p(p-1)(k_{1} - k_{2})\mathbf{1}_{n\times n} \\ -\alpha\mathbf{I}_{n} - \frac{\alpha}{n(p-1)}\mathbf{1}_{n\times n} - \alpha^{2}p(k_{1} - k_{2})\mathbf{1}_{n\times n} \end{pmatrix} = \mathcal{M}_{p} \begin{pmatrix} \mathbf{Q} \\ -\alpha\mathbf{I}_{n} \end{pmatrix} = \boldsymbol{\Theta}.\n\end{split}
$$

Similarly we prove that  $\tilde{\mathbf{K}}\boldsymbol{\Theta}\tilde{\mathbf{K}} = \tilde{\mathbf{K}}$ :

$$
\begin{split}\n\mathbf{K}\Theta\mathbf{K} &= \mathcal{M}_{p} \left( \sum_{\mathbf{X}} \right) \mathcal{M}_{p} \left( -\frac{\mathbf{I}_{n}}{n(p-1)} \mathbf{1}_{n \times n} \right) = \mathcal{M}_{p} \left( -\frac{\Sigma - \frac{1}{n} \mathbf{X} \mathbf{1}_{n \times n}}{n(p-1)} \mathbf{\Sigma} \mathbf{1}_{n \times n} + \mathbf{X} - \frac{p-2}{n(p-2)} \mathbf{X} \mathbf{1}_{n \times n} \right) \\
&= \mathcal{M}_{p} \left( \sum_{\mathbf{X}} + \frac{\frac{1}{\alpha n(p-1)} \mathbf{1}_{n \times n}}{n(p-1)^{2}} \mathbf{1}_{n \times n} \right) \\
&= \mathcal{M}_{p} \left( \frac{k_{1} \mathbf{1}_{n \times n}}{k_{2} \mathbf{1}_{n \times n}} \right) \Theta\mathbf{K} = \mathbf{K}\Theta \mathcal{M}_{p} \left( \frac{k_{1} \mathbf{1}_{n \times n}}{k_{2} \mathbf{1}_{n \times n}} \right) \\
&= \mathcal{M}_{p} \left( \frac{k_{1} \mathbf{1}_{n \times n}}{k_{2} \mathbf{1}_{n \times n}} \right) \mathcal{M}_{p} \left( -\frac{\mathbf{I}_{n}}{n(p-1)} \mathbf{1}_{n \times n} \right) \\
&= \mathcal{M}_{p} \left( -\frac{k_{1}}{n(p-1)} \mathbf{1}_{n \times n} + k_{2} \mathbf{1}_{n \times n} - \frac{k_{2}(p-2)}{n(p-1)} \mathbf{1}_{n \times n} \mathbf{1}_{n \times n} \right) \\
&= \mathcal{M}_{p} \left( \frac{(k_{1} - k_{2}) \mathbf{1}_{n \times n}}{k_{2} \mathbf{1}_{n \times n}} \right) \\
&= \mathcal{M}_{p} \left( \frac{k_{1} \mathbf{1}_{n \times n}}{k_{2} \mathbf{1}_{n \times n}} \right) \Theta \mathcal{M}_{p} \left( \frac{k_{1} \mathbf{1}_{n \times n}}{k_{2} \mathbf{1}_{n \times n}} \right) \\
&= \mathcal{M}_{p} \left( \frac{k_{1} \mathbf{1}_{n \times n}}{
$$

Therefore,

$$
\tilde{\mathbf{K}}\mathbf{\Theta}\tilde{\mathbf{K}}=\mathbf{K}\mathbf{\Theta}\mathbf{K}+2\,\mathcal{M}_p\begin{pmatrix}k_1\mathbf{1}_{n\times n}\\\k_2\mathbf{1}_{n\times n}\end{pmatrix}\mathbf{\Theta}\mathbf{K}+\mathcal{M}_p\begin{pmatrix}k_1\mathbf{1}_{n\times n}\\\k_2\mathbf{1}_{n\times n}\end{pmatrix}\mathbf{\Theta}\mathcal{M}_p\begin{pmatrix}k_1\mathbf{1}_{n\times n}\\\k_2\mathbf{1}_{n\times n}\end{pmatrix}=\tilde{\mathbf{K}}.
$$

*Proof of Proposition [3.](#page-14-0)* We first show that Θ is quasi-Laplacian. To this end, we need to show that  $\Theta$  is symmetric, positive semidefinite,  $\Theta 1_{np} = 0$ , and Θ has only one null eigenvalue.

- 1. Since **Q** and  $\alpha \mathbf{I}_n$  are symmetric and  $\mathbf{\Theta} := \mathcal{M}_p(\mathbf{Q}, -\alpha \mathbf{I}_n)$ ,  $\mathbf{\Theta}$  is symmetric.
- 2. First recall that  $\mathbf{\Theta} = \mathbf{I}_p \otimes (\mathbf{Q} + \alpha \mathbf{I}_n) + \mathbf{1}_{p \times p} \otimes (-\alpha \mathbf{I}_n)$ : we aim to apply Lemma [A.4](#page-36-0) to the matrix  $\Theta$  with  $\mathbf{X} := \mathbf{I}_p \otimes (\mathbf{Q} + \alpha \mathbf{I}_n)$  and  $\mathbf{Y} :=$

 $\mathbf{1}_{p\times p} \otimes (-\alpha \mathbf{I}_n)$ . In the following, we write  $\lambda(\mathbf{A})$  to denote the vector of eigenvalues of **A**. In addition, the inequalities apply to all elements: we write  $\lambda(A) \geq c$  as a shortcut of  $\forall i \in \{1, ..., n\}$ ,  $\lambda_i(A) \geq c$ , for an  $n \times n$  matrix **A**.

$$
\lambda(\mathbf{X}) = \lambda(\mathbf{I}_p \otimes (\mathbf{Q} + \alpha \mathbf{I}_n)) = \lambda(\mathbf{I}_p) \otimes \lambda(\mathbf{Q} + \alpha \mathbf{I}_n) = \mathbf{1}_p \otimes (\lambda(\mathbf{Q}) + \alpha)
$$
  
\n
$$
\geq \lambda_n(\mathbf{Q}) + \alpha = \alpha(p-1) + \alpha = \alpha p
$$
  
\n
$$
\lambda(\mathbf{Y}) = \lambda(\mathbf{1}_{p \times p} \otimes (-\alpha \mathbf{I}_n)) = \begin{bmatrix} p \\ 0 \\ \vdots \\ 0 \end{bmatrix} \otimes \begin{bmatrix} -\alpha \\ \vdots \\ -\alpha \end{bmatrix} \geq -\alpha p.
$$

Therefore  $\Theta$  is positive semidefinite.

3. To show  $\Theta 1_{np} = 0$ , given the special structure of  $\Theta$ , it is sufficient to show that

$$
\begin{bmatrix} \mathbf{Q} & -\alpha \mathbf{I}_n & \dots & -\alpha \mathbf{I}_n \end{bmatrix} \mathbf{1}_{np} = \mathbf{0},
$$

*i.e.*  $\mathbf{Q1}_n = \alpha(p-1)\mathbf{1}_n$ , which has already been proved in Lemma [A.2.](#page-34-0)

4. We now need to show that Θ has no other null eigenvalues, *i.e.* the only solution to

<span id="page-40-0"></span>
$$
\begin{bmatrix}\n\mathbf{Q} & -\alpha \mathbf{I}_n & \dots & -\alpha \mathbf{I}_n \\
-\alpha \mathbf{I}_n & \mathbf{Q} & \dots & -\alpha \mathbf{I}_n \\
\vdots & \vdots & \ddots & \vdots \\
-\alpha \mathbf{I}_n & -\alpha \mathbf{I}_n & \dots & \mathbf{Q}\n\end{bmatrix}\n\begin{bmatrix}\n\mathbf{v}_1 \\
\mathbf{v}_2 \\
\vdots \\
\mathbf{v}_n\n\end{bmatrix} = \n\begin{bmatrix}\n\mathbf{0} \\
\mathbf{0} \\
\vdots \\
\mathbf{0}\n\end{bmatrix}
$$
\n(49)

is (up to a multiplicative constant)  $v_1 = \cdots = v_n = 1_n$ . By reading Equation [\(49\)](#page-40-0) by blocks, we get the following:  $\forall i \in \{1, \ldots, n\}$ 

$$
\mathbf{Q}\boldsymbol{v}_i - \alpha \sum_{k \neq i} \boldsymbol{v}_k = \mathbf{0}.
$$

Taking now the difference for  $i = i$  and  $i = j$ , we get

$$
(\mathbf{Q}+\alpha\mathbf{I}_n)(\boldsymbol{v}_i-\boldsymbol{v}_j)=\mathbf{0}
$$

and, since  $\mathbf{Q} + \alpha \mathbf{I}_n$  is strictly positive definite directly by Lemma [A.2,](#page-34-0) we obtain that  $v_i = v_j = v$  for all *i, j*. The problem thus becomes

$$
(\mathbf{Q} - \alpha(p-1)\mathbf{I}_n)\mathbf{v} = \mathbf{0}.
$$

To conclude it is sufficient to notice that the eigenvalues of  $\mathbf{Q} - \alpha (p - \alpha)$ 1)**I**<sub>n</sub> are  $\lambda_i(\mathbf{Q}) - \alpha(p-1)$  and, by Lemma [A.2,](#page-34-0) all the eigenvalues are not less than  $\alpha(p-1)$  and exactly one achieve such a value. As a consequence, the kernel of  $\mathbf{Q}$ −*α*(*p*−1)**I**<sub>*n*</sub> has dimension one and, since we already know that  $(Q - \alpha(p-1)I_n)I_n = 0$ , the only possibility is  $v=\mathbf{1}_n.$ 

That  $\Theta^-$  is also a quasi-Laplacian matrix comes from Lemma [A.5](#page-36-1) and the closure of the set of quasi-Laplacian matrices under Moore-Penrose inversion (Proposition [1\)](#page-8-0).

 $\Box$ 

*Proof of Proposition* [4.](#page-15-1) It is sufficient to apply Proposition [2](#page-11-0) with  $X := V$ . We show that the  $np \times np$  matrix  $[\mathbf{K}(v_i, v_j)]_{i,j=1}^{np}$  is positive semidefinite. First, notice that  $[\mathbf{K}(v_i, v_j)]_{i,j=1}^{np} = \mathcal{M}_p\left(\tilde{\Sigma}, \tilde{\mathbf{X}}\right) = \tilde{\mathbf{K}}$ . Since  $\tilde{\mathbf{K}} \in \mathbb{R}^{np \times np}$  is positive semidefinite (see Lemma  $A.5$  and Proposition [3\)](#page-14-0), each matrix  $C$  as defined in Proposition [2,](#page-11-0) being a principal submatrix of  $\bf{K}$ , is positive semidefinite as well. This proves the Proposition.  $\Box$ 

- *Proof of Proposition [7.](#page-16-0)* 1. The proof of this point is straightforward, as the pseudo variogram only takes non-negative values.
	- 2. The condition  $u_1 = u_2$  and  $i = j$  is sufficient to have  $D_{ii}(u_1, u_2) = 0$  due to the fact that the diagonal entries of  $\Gamma_Z(u_1, u_1)$  are zero. Let us show that it is also necessary. From the definition of the pseudo-variogram as per Equation [\(6\)](#page-10-1),  $D_{ij}(u_1, u_2) = 0$  if and only if  $Z_i(u_1) = Z_j(u_2)$ . Since  $\mathbf{Z} = \mathbf{Z}_V + \mathbf{Z}_E$  with  $\mathbf{Z}_V$  and  $\mathbf{Z}_E$  being mutually independent, a necessary condition is that  $Z_{V,i}(u_1) = Z_{V,j}(u_2)$ . Given the correlation structure [\(22\)](#page-14-5) at the vertices, the variance-covariance matrix  $\tilde{\mathbf{K}}$  of  $\mathbf{Z}_V\Big|_V$ is quasi-Laplacian (Lemma [A.5](#page-36-1) and Proposition [3\)](#page-14-0) and thus it has only one null eigenvalue associated with the vector  $\mathbf{1}_{np}$ . That is, the only non-trivial linear combination of  $Z_V\vert_V$  having a zero variance is, up to a constant factor,  $\mathbf{1}_{np}^\top \mathbf{Z}_V \Big|_V$ . Therefore,  $Z_{V,i}(u_1) = Z_{V,j}(u_2)$  for  $u_1, u_2 \in V$  only if  $i = j$  and  $u_1 = u_2$ . Given the linear interpolation on the edges (Equation  $(23)$ ), the same holds true for any two points  $u_1$ and  $u_2$  belonging to  $\mathcal{G}$ .
	- 3. The claim stems from Equations [\(8\)](#page-10-2) and [\(29\)](#page-16-4).

4. Let  $u_0, u_1, \ldots, u_n \in \mathcal{G}$  and  $\mathbf{c}_1, \ldots, \mathbf{c}_n \in \mathbb{R}^p$ . Let  $\mathbf{c}_0 = -\mathbf{A} \sum_{i=1}^n \mathbf{c}_i$ , where **A** is a  $p \times p$  matrix such that  $\mathbf{A}^\top \mathbf{1}_p = \mathbf{1}_p$ . Then, from Equation [\(9\)](#page-10-3), one has:

$$
0 \geq \sum_{i,j=0}^{n} \mathbf{c}_{i}^{\top} \mathbf{\Gamma}_{\mathbf{Z}}(u_{i}, u_{j}) \mathbf{c}_{j}
$$
  
\n
$$
= \sum_{i,j=1}^{n} \mathbf{c}_{i}^{\top} \mathbf{\Gamma}_{\mathbf{Z}}(u_{i}, u_{j}) \mathbf{c}_{j} + \sum_{i=1}^{n} \mathbf{c}_{i}^{\top} \mathbf{\Gamma}_{\mathbf{Z}}(u_{i}, u_{0}) \mathbf{c}_{0} + \sum_{j=1}^{n} \mathbf{c}_{0}^{\top} \mathbf{\Gamma}_{\mathbf{Z}}(u_{0}, u_{j}) \mathbf{c}_{j} + \mathbf{c}_{0}^{\top} \mathbf{\Gamma}_{\mathbf{Z}}(u_{0}, u_{0}) \mathbf{c}_{0}
$$
  
\n
$$
= \sum_{i,j=1}^{n} \mathbf{c}_{i}^{\top} \left[ \mathbf{\Gamma}_{\mathbf{Z}}(u_{i}, u_{j}) - \mathbf{\Gamma}_{\mathbf{Z}}(u_{i}, u_{0}) \mathbf{A} - \mathbf{A}^{\top} \mathbf{\Gamma}_{\mathbf{Z}}(u_{0}, u_{j}) + \mathbf{A}^{\top} \mathbf{\Gamma}_{\mathbf{Z}}(u_{0}, u_{0}) \mathbf{A} \right] \mathbf{c}_{j},
$$

*i.e.*, the mapping  $(u, v) \mapsto -[\Gamma_{\mathbf{Z}}(u, v) - \Gamma_{\mathbf{Z}}(u, u_0) \mathbf{A} - \mathbf{A}^\top \Gamma_{\mathbf{Z}}(u_0, v) +$  $\mathbf{A}^{\top} \Gamma_{\mathbf{Z}}(u_0, u_0) \mathbf{A}$ ] is positive semidefinite (Equation [12\)](#page-11-1).

5. Taking  $c_1 = \ldots = c_n := c$  and  $A = I_p$ , one gets

$$
0 \geq \mathbf{c}^\top \sum_{i,j=1}^n \left[ \mathbf{\Gamma}_{\mathbf{Z}}(u_i, u_j) - \mathbf{\Gamma}_{\mathbf{Z}}(u_i, u_0) - \mathbf{\Gamma}_{\mathbf{Z}}(u_0, u_j) + \mathbf{\Gamma}_{\mathbf{Z}}(u_0, u_0) \right] \mathbf{c}.
$$

Accounting for the fact that  $\Gamma_Z = \Gamma_Z^{\top}$  and  $\Gamma_Z(u_0, u_0) = \Gamma_Z(u_1, u_1) =$  $\Gamma_{\mathbf{Z}}(u_2, u_2)$ , one obtains, for  $n = 1$  and  $u_0 = u_2$ .

$$
0 \geq \boldsymbol{c}^\top \left[\boldsymbol{\Gamma}_{\boldsymbol{Z}}(u_0,u_0) - \boldsymbol{\Gamma}_{\boldsymbol{Z}}(u_1,u_2)\right] \boldsymbol{c},
$$

and for  $n = 2$ :

$$
0 \geq \mathbf{c}^\top \left[ \mathbf{\Gamma}_{\mathbf{Z}}(u_1, u_2) + 3 \mathbf{\Gamma}_{\mathbf{Z}}(u_0, u_0) - 2 \mathbf{\Gamma}_{\mathbf{Z}}(u_1, u_0) - 2 \mathbf{\Gamma}_{\mathbf{Z}}(u_2, u_0) \right] \mathbf{c},
$$

*i.e.*,  $\Gamma_Z(u_1, u_2) - \Gamma_Z(u_0, u_0)$  and  $2\Gamma_Z(u_1, u_0) + 2\Gamma_Z(u_2, u_0) - \Gamma_Z(u_1, u_2)$  $3\Gamma_Z(u_0, u_0)$  are positive semidefinite matrices.

$$
\qquad \qquad \Box
$$

*Proof of Proposition [8.](#page-17-1)* 1. We split the computation of the distances (the one proposed here, **D**, and the one defined by [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0),  $d_R$ ) in two: the contribution (*i.e.* the variogram) of the  $Z_V$  process and the one of  $\mathbf{Z}_E$ , denoted via the superscripts *V* and *E* respectively. We show that  $\mathbf{D}_{ii}^V(u_1, u_2) = d_R^V(u_1, u_2)$  and  $\mathbf{D}_{ii}^E(u_1, u_2) = d_R^E(u_1, u_2)$ . The latter comes straightforwardly by comparing the diagonal entries

of Equation [\(24\)](#page-15-2), *i.e.*  $\mathbb{1}$  ( $e_1 = e_2$ )  $\ell(e_1)$  ( $\delta_1 \wedge \delta_2 - \delta_1 \delta_2$ ), with the kernel *R<sup>e</sup>* in [Anderes et al.](#page-27-0) [\[2020,](#page-27-0) Equation 15].

Thus, let us show that  $\mathbf{D}_{ii}^V(u_1, u_2) = d_R^V(u_1, u_2)$ . Let  $u_1, u_2 \in \mathcal{G}$  and  $k_{V,ii}$ be the *i*-th diagonal entry of  $\mathbf{K}_{\mathbf{Z}_V}$ . Then, on account of Proposition [5:](#page-15-0)

$$
\mathbf{D}_{ii}^V(u_1, u_2) = k_{V,ii}(u_1, u_1) + k_{V,ii}(u_2, u_2) - 2k_{V,ii}(u_1, u_2)
$$
\n
$$
= \boldsymbol{\delta}_{1,V}^\top \tilde{\boldsymbol{\Sigma}} \boldsymbol{\delta}_{1,V} + \boldsymbol{\delta}_{2,V}^\top \tilde{\boldsymbol{\Sigma}} \boldsymbol{\delta}_{2,V} - 2\boldsymbol{\delta}_{1,V}^\top \tilde{\boldsymbol{\Sigma}} \boldsymbol{\delta}_{2,V}
$$
\n
$$
= (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^\top (\boldsymbol{\Sigma} + k_1 \mathbf{1}_{n \times n}) (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})
$$
\n
$$
= (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^\top \boldsymbol{\Sigma} (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V}) + k_1 (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^\top \mathbf{1}_{n \times n} (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})
$$
\n
$$
= (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^\top \boldsymbol{\Sigma} (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V}),
$$

where in the last step we have used  $\boldsymbol{\delta}_{1,V}^{\top} \mathbf{1}_n = \boldsymbol{\delta}_{2,V}^{\top} \mathbf{1}_n = 1$  owing to Equation [\(26\)](#page-15-4).

It is left to show that this quantity coincides with the resistance counterpart of [Anderes et al.](#page-27-0) [\[2020\]](#page-27-0). They define their covariance matrix, here denoted by  $\Sigma_A$ , as the (proper) inverse of a modified Laplacian matrix **L**, where a one has been added on an arbitrary diagonal entry. In formulae:  $\Sigma_A := (L + e_j e_j^{\top})^{-1}$ , where  $e_j$  is the *j*<sup>th</sup> vector of the canonical basis of  $\mathbb{R}^n$ . It follows directly from [Anderes et al.](#page-27-0) [\[2020,](#page-27-0) Equation 13] that  $d_R^V = (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^\top \Sigma_{\mathbf{A}} (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V}).$ 

Let us show that, for a given quasi-Laplacian matrix **L** and for any  $\boldsymbol{x} \in \mathbb{R}^n$  such that  $\boldsymbol{1}_n^\top \boldsymbol{x} \neq 0$ , it holds:

<span id="page-43-0"></span>
$$
\left(\boldsymbol{\delta}_{1,V}-\boldsymbol{\delta}_{2,V}\right)^{\top}\left(\mathbf{L}+\boldsymbol{x}\,\boldsymbol{x}^{\top}\right)^{-}\left(\boldsymbol{\delta}_{1,V}-\boldsymbol{\delta}_{2,V}\right)=\left(\boldsymbol{\delta}_{1,V}-\boldsymbol{\delta}_{2,V}\right)^{\top}\mathbf{L}^{-}\left(\boldsymbol{\delta}_{1,V}-\boldsymbol{\delta}_{2,V}\right).
$$
\n(50)

In order to express the Moore-Penrose inverse of the rank-1 update  $\mathbf{L} + \mathbf{x} \mathbf{x}^{\mathsf{T}}$ , we exploit Theorem 1 of [Meyer](#page-30-6) [\[1973\]](#page-30-6) with  $\mathbf{A} := \mathbf{L}$  and  $c := d := x$ . Firstly, let us show that the hypotheses of the theorem are satisfied: we have to prove that  $x \notin R(\mathbf{L})$ , where R denotes the range or column space.  $R(\mathbf{L})$  is perpendicular to the kernel of  $\mathbf{L}$ , that is (recall that **L** is a quasi-Laplacian matrix) ker(**L**) =  $\{h\mathbf{1}_n : h \in \mathbb{R}\}.$ Now,  $\mathbf{x} \in R(\mathbf{L}) \iff \mathbf{x} \perp \ker(\mathbf{L}) \iff \mathbf{1}_n^\top \mathbf{x} = 0$ , yet  $\mathbf{1}_n^\top \mathbf{x} \neq 0$ by hypothesis. Therefore  $x \notin R(L)$ , *i.e.* we can apply the abovementioned theorem. In the following computations, we have adopted

the notation used by [Meyer](#page-30-6) [\[1973,](#page-30-6) Section 2], *i.e.* :

$$
\begin{aligned} \boldsymbol{k} &:= \mathbf{L}^- \boldsymbol{x} & \boldsymbol{h} &:= \boldsymbol{x}^\top \mathbf{L}^- \\ \boldsymbol{u} &:= \left(\mathbf{I}_n - \mathbf{L} \mathbf{L}^- \right) \boldsymbol{x} = \frac{1}{n} \mathbf{1}_{n \times n} \boldsymbol{x} & \boldsymbol{v} &:= \boldsymbol{x}^\top \left(\mathbf{I}_n - \mathbf{L}^- \mathbf{L}\right) = \frac{1}{n} \boldsymbol{x}^\top \mathbf{1}_{n \times n} \\ \beta &:= 1 + \boldsymbol{x}^\top \mathbf{L}^- \boldsymbol{x}. \end{aligned}
$$

In addition, we have  $||u||^2 = ||v||^2 = u^{\top}u = \frac{1}{n^2} \mathbf{1}_n^{-\top}(\mathbf{1}_n^{-\top}x)(\mathbf{1}_n^{-\top}x)\mathbf{1}_n =$ <br> $\frac{1}{n}(\mathbf{1}_n^{-\top}x)^2 \neq 0$ . Let us finally apply Equation (3.1) of Moyer [1073].  $\frac{1}{n}$ (**1**<sub>*n*</sub><sup>T</sup>*x*)<sup>2</sup> ≠ 0. Let us finally apply Equation (3.1) of [Meyer](#page-30-6) [\[1973\]](#page-30-6):

$$
\begin{aligned} \left(\mathbf{L}+\boldsymbol{x}\boldsymbol{x}^{\top}\right)^{-}&=\mathbf{L}^{-}-\boldsymbol{k}\boldsymbol{u}^{-}-\boldsymbol{v}^{-}\boldsymbol{h}+\beta\boldsymbol{v}^{-}\boldsymbol{u}^{-}\\ &=\mathbf{L}^{-}-\frac{\boldsymbol{k}\boldsymbol{u}^{\top}}{\left\|\boldsymbol{u}\right\|^{2}}-\frac{\boldsymbol{v}^{\top}\boldsymbol{h}}{\left\|\boldsymbol{v}\right\|^{2}}+\beta\frac{\boldsymbol{v}^{\top}\boldsymbol{u}^{\top}}{\left\|\boldsymbol{v}\right\|^{2}\left\|\boldsymbol{u}\right\|^{2}}\\ &=\mathbf{L}^{-}-\frac{\mathbf{L}^{-}\boldsymbol{x}\mathbf{1}_{n}^{\top}}{\mathbf{1}_{n}^{\top}\boldsymbol{x}}-\frac{\mathbf{1}_{n}\boldsymbol{x}^{\top}\mathbf{L}^{-}}{\mathbf{1}_{n}^{\top}\boldsymbol{x}}+\left(1+\boldsymbol{x}^{\top}\mathbf{L}^{-}\boldsymbol{x}\right)\frac{\mathbf{1}_{n\times n}}{\left(\mathbf{1}_{n}^{\top}\boldsymbol{x}\right)^{2}}.\end{aligned}
$$

To show  $(50)$ , it is now sufficient to prove that

$$
\left(\boldsymbol{\delta}_{1,V}-\boldsymbol{\delta}_{2,V}\right)^{\top}\left(\left(1+\boldsymbol{x}^{\top}\mathbf{L}^{-}\boldsymbol{x}\right)\frac{\mathbf{1}_{n\times n}}{\left(\mathbf{1}_{n}^{\top}\boldsymbol{x}\right)^{2}}-\frac{\mathbf{L}^{-}\boldsymbol{x}\mathbf{1}_{n}^{\top}}{\mathbf{1}_{n}^{\top}\boldsymbol{x}}-\frac{\mathbf{1}_{n}\boldsymbol{x}^{\top}\mathbf{L}^{-}}{\mathbf{1}_{n}^{\top}\boldsymbol{x}}\right)\left(\boldsymbol{\delta}_{1,V}-\boldsymbol{\delta}_{2,V}\right)=0.
$$

It is possible to see this by noticing that  $\mathbf{1}_n^\top (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V}) = \mathbf{1}_n^\top \boldsymbol{\delta}_{1,V} \mathbf{1}_n \mathbf{I}_{\mathbf{z}} \delta_{2,V} = 1 - 1 = 0$  and similarly  $(\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^{\top} \mathbf{1}_n = 0$ , therefore each term of the above equation equals 0.

As a consequence,

$$
d_K^V(u_1, u_2) = (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^\top \Sigma_{\mathbf{A}} (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})
$$
  
=  $(\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^\top (\mathbf{L} + \boldsymbol{e}_j \boldsymbol{e}_j^\top)^\top (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})$   
=  $(\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^\top \mathbf{L}^\top (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V}) = D_{ii}^V(u_1, u_2).$ 

2. The proof of this point is straightforward from Equation [\(29\)](#page-16-4): notice that  $D_{ij}(u_1, u_2)$ , for  $i \neq j$ , is the off-diagonal element of  $\mathbf{D}(u_1, u_2)$ , whilst  $D_{ii}(u_1, u_2)$  is the main diagonal one.

 $\Box$ 

*Proof of Proposition [9.](#page-17-2)* We prove each row of the table, in turn. In the following computations, ∼*<sup>a</sup>* stands for "asymptotically equivalent to".

1. Fix  $\alpha > 0$  and let  $p \to +\infty$ . Considering Equations [\(19\)](#page-14-1) and [\(21\)](#page-14-2), we have:

<span id="page-45-1"></span>
$$
\mathbf{\Lambda}^{-} + \alpha (p - 2) \mathbf{I}_{n} + \sqrt{(\mathbf{\Lambda}^{-})^{2} - 2\alpha (p - 2)\mathbf{\Lambda}^{-} + \alpha^{2} p^{2} \mathbf{I}_{n}}
$$
(51)  

$$
\sim_{a} \alpha (p - 2) \mathbf{I}_{n} + \alpha p \mathbf{I}_{n} = 2\alpha (p - 1) \mathbf{I}_{n}
$$

<span id="page-45-2"></span>
$$
\alpha(p-2)\Lambda + \sqrt{\mathbf{I}_n - \mathbf{J}_n - 2\alpha(p-2)\Lambda + \alpha^2 p^2 \Lambda^2} - \mathbf{I}_n - \mathbf{J}_n \qquad (52)
$$

$$
\sim_a \alpha(p-2)\Lambda + \alpha p\Lambda = 2\alpha(p-1)\Lambda.
$$

As a consequence,  $\mathbf{Q} \sim_a \alpha(p-1)\mathbf{I}_n$  and  $\mathbf{X} \to \Sigma$ . Furthermore,  $k_1, k_2 \to$ 0 and thus  $\Sigma, X \to \Sigma$  as  $p \to +\infty$ . From this last relation, we obtain that the process  $\mathbf{Z}_V$  satisfies  $\mathbb{C}$  or  $(Z_{V,i}, Z_{V,j}) \to 1$  for all  $i, j \in \{1, \ldots, p\}$ . Throughout the whole proof, the expression for the distance changes only via the first line of Equation [\(29\)](#page-16-4), reported below for an neat exposition.

$$
\delta_{1,V}^{\top} \tilde{\Sigma} \delta_{1,V} + \delta_{2,V}^{\top} \tilde{\Sigma} \delta_{2,V} - 2 \delta_{1,V}^{\top} \tilde{\mathbf{X}} \delta_{2,V} \n= \delta_{1,V}^{\top} \Sigma \delta_{1,V} + \delta_{2,V}^{\top} \Sigma \delta_{2,V} - 2 \delta_{1,V}^{\top} \mathbf{X} \delta_{2,V} + 2k_1 - 2k_2.
$$
\n(53)

In this case,

<span id="page-45-0"></span>
$$
(53) \rightarrow (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^{\top} \tilde{\boldsymbol{\Sigma}} (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})
$$

If we add the hypothesis  $\beta \to 1$ ,  $\mathbb{C}\text{or } (Z_{E,i}, Z_{E,j}) \to 1$  as well. This implies that all the  $p \times p$  entries of  $\mathbf{D}(u_1, u_2)$  converge to the same term, that is  $d_R(u_1, u_2)$ .

- 2. Fix  $p > 2$  and let  $\alpha \to +\infty$ . The same asymptotic properties [\(51\)](#page-45-1) and [\(52\)](#page-45-2) hold (notice that  $p$  and  $\alpha$  always appear with the same exponent in each monomial). Therefore, the same reasoning applies.
- 3. Fix  $p \geq 2$  and let  $\alpha \to 0^+$ . From Equation [\(18\)](#page-14-3), it is patent that  $\mathbf{Q} \rightarrow \frac{1}{2}(\mathbf{L} + \sqrt{\mathbf{L}^2}) = \mathbf{L}$ ; whilst from Equation [\(21\)](#page-14-2), we have:

$$
\mathbf{X} = \frac{1}{2(p-1)} \mathbf{W} \left( (p-2) \mathbf{\Lambda} + \frac{1}{\alpha} \sqrt{\mathbf{I}_n - \mathbf{J}_n - 2\alpha (p-2) \mathbf{\Lambda} + \alpha^2 p^2 \mathbf{\Lambda}} - \frac{1}{\alpha} \mathbf{I}_n - \frac{1}{\alpha} \mathbf{J}_n \right) \mathbf{W}^\top.
$$

Consider the diagonal matrix in the big brackets: it is possible to ex-Consider the diagonal matrix in the big brackets: it is possible to ex-<br>pand the square root term by means of the Taylor expansion  $\sqrt{a-b\cdot\alpha+c\cdot\alpha^2}=$  √  $\overline{a} - \frac{b}{2a}$  $\frac{b}{2\sqrt{a}}\alpha + o(\alpha)$  as  $\alpha \to 0^+$ : the *i*<sup>th</sup> element on the main diagonal of  $\sqrt{\mathbf{I}_n - \mathbf{J}_n - 2\alpha(p-2)\mathbf{\Lambda} + \alpha^2 p^2 \mathbf{\Lambda}}$  is therefore:

$$
\begin{cases}\n\sqrt{1} - \frac{2(p-2)\lambda_i}{2\sqrt{1}}\alpha + o(\alpha) = 1 - (p-2)\lambda_i \alpha + o(\alpha) & \text{if } i \neq n \\
0 & \text{if } i = n.\n\end{cases}
$$

As a consequence, we have:

$$
(p-2)\Lambda + \frac{1}{\alpha}\sqrt{\mathbf{I}_n - \mathbf{J}_n - 2\alpha(p-2)\Lambda + \alpha^2 p^2 \Lambda} - \frac{1}{\alpha}\mathbf{I}_n - \frac{1}{\alpha}\mathbf{J}_n
$$
  

$$
\sim_a (p-2)\Lambda + \frac{1}{\alpha}(\mathbf{I}_n - \mathbf{J}_n) - (p-2)\Lambda - \frac{1}{\alpha}\mathbf{I}_n - \frac{1}{\alpha}\mathbf{J}_n
$$
  

$$
= -\frac{2}{\alpha}\mathbf{J}_n,
$$

that is:

$$
\mathbf{X} \sim \frac{1}{2(p-1)} \mathbf{W} \left( -\frac{2}{\alpha} \mathbf{J}_n \right) \mathbf{W}^{\top} = -\frac{1}{\alpha(p-1)} \frac{1}{n} \mathbf{1}_{n \times n},
$$

where in the last step we have used from the proof of Lemma [A.3](#page-35-0) that  $\mathbf{W}\mathbf{J}_n\mathbf{W}^\top = \frac{1}{n}$  $\frac{1}{n}$ **1**<sub>*n*×*n*</sub> (Equation [\(47\)](#page-35-1)). In this case

$$
(53) \sim_a \boldsymbol{\delta}_{1,V}^{\top} \boldsymbol{\Sigma} \boldsymbol{\delta}_{1,V} + \boldsymbol{\delta}_{2,V}^{\top} \boldsymbol{\Sigma} \boldsymbol{\delta}_{2,V} - 2 \boldsymbol{\delta}_{1,V}^{\top} \left( -\frac{1}{\alpha n(p-1)} \mathbf{1}_{n \times n} \right) \boldsymbol{\delta}_{2,V} - 2 \frac{1}{\alpha np(p-1)}
$$

$$
= \boldsymbol{\delta}_{1,V}^{\top} \boldsymbol{\Sigma} \boldsymbol{\delta}_{1,V} + \boldsymbol{\delta}_{2,V}^{\top} \boldsymbol{\Sigma} \boldsymbol{\delta}_{2,V} + \frac{2}{\alpha np}.
$$

Clearly, the contribution of the process  $\mathbb{Z}_E$  in Equation [\(29\)](#page-16-4) and the above term  $\delta_{1,V}^{\top} \Sigma \delta_{1,V} + \delta_{2,V}^{\top} \Sigma \delta_{2,V}$  do not depend on *α*. As a consequence,  $D_{ij}(u_1, u_2) \sim_a \frac{2}{\alpha m}$  $\frac{2}{\alpha np}$  for  $i \neq j$  as  $\alpha \to 0^+$ .

4. Let  $\alpha \to 0^+$  and  $p \to +\infty$  such that  $\alpha p\tau \to 1$  with  $0 < \tau \leq \lambda_{n-1}$  being fixed. Then, from Equations [\(19\)](#page-14-1) and [\(46\)](#page-33-1), one has  $Q \to \frac{I_n}{\tau}$ . Likewise, from Equation [\(21\)](#page-14-2), it comes  $\mathbf{X} \to \Sigma - \tau \mathbf{I}_n$ . The computation of the distances  $D_{ij}(u_1, u_2)$  is straightforward: following the same reasoning of the previous derivation, we have

$$
(53) = \boldsymbol{\delta}_{1,V}^{\top} \boldsymbol{\Sigma} \boldsymbol{\delta}_{1,V} + \boldsymbol{\delta}_{2,V}^{\top} \boldsymbol{\Sigma} \boldsymbol{\delta}_{2,V} - 2 \boldsymbol{\delta}_{1,V}^{\top} (\boldsymbol{\Sigma} - \tau \mathbf{I}_n) \, \boldsymbol{\delta}_{2,V} - 2 \frac{1}{\alpha np(p-1)} \n\to (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V})^{\top} \boldsymbol{\Sigma} (\boldsymbol{\delta}_{1,V} - \boldsymbol{\delta}_{2,V}) + 2 \tau \boldsymbol{\delta}_{1,V}^{\top} \boldsymbol{\delta}_{2,V}.
$$

The first addendum, together with the contribution of the process  $\mathbf{Z}_E$ (if  $\beta \rightarrow 1$ ), gives the distance  $d_R(u_1, u_2)$ .

5. Let  $\alpha \to 0^+$  and  $p \to +\infty$ , with  $\alpha p \to 1$  with  $\tau \geq \lambda_1$  fixed. Equation  $(19)$  gives

$$
\mathbf{Q} \to \mathbf{W} \operatorname{diag} \left[ \lambda_1^{-1}, \ldots, \lambda_{n-1}^{-1}, \frac{1}{\tau} \right]^\top \mathbf{W}^\top = \mathbf{W} \left( \mathbf{\Lambda}^- + \frac{1}{\tau} \mathbf{J}_n \right) \mathbf{W}^\top = \mathbf{L} + \frac{1}{n\tau} \mathbf{1}_{n \times n}.
$$

Therefore, from Equation [\(20\)](#page-14-4):

$$
\mathbf{X} = \frac{p\tau}{p-1} \left( \mathbf{\Sigma} \left( \mathbf{L} + \frac{1}{n\tau} \mathbf{1}_{n \times n} \cdot \right) - \mathbf{I}_n \right) \to -\frac{\tau}{n} \mathbf{1}_{n \times n}, \quad \text{as } p \to +\infty.
$$

Hence,

$$
(53) \rightarrow \delta_{1,V}^{\top} \Sigma \delta_{1,V} + \delta_{2,V}^{\top} \Sigma \delta_{2,V} - 2\delta_{1,V}^{\top} \left(-\frac{\tau}{n} \mathbf{1}_{n \times n}\right) \delta_{2,V} - 2\frac{1}{\alpha np(p-1)} \rightarrow \delta_{1,V}^{\top} \Sigma \delta_{1,V} + \delta_{2,V}^{\top} \Sigma \delta_{2,V} + \frac{2\tau}{n}.
$$

The result for the distance  $D_{ij}(u_1, u_2)$  is obtained from the last equation by adding and subtracting  $2\delta_{1,V}^{\top} \mathbf{X} \delta_{2,V}$  and by using the fact that  $\beta \to 1$ .

 $\Box$ 

*Proof of Theorem [3.1.](#page-17-0)* The result stems from Theorem [2.2](#page-12-1) and the fact that the pseudo-variogram **D** satisfies  $\mathbf{D}^\top(u_1, u_2) = \mathbf{D}(u_2, u_1)$  and is  $\mathbf{1}_p$ -conditionally negative semidefinite.

*Proof of Theorem [3.2.](#page-19-0)* The result stems from Theorem [3.1](#page-17-0) with  $\psi(t) = \exp(-t)$ and  $g(t) = t^{\theta}$  and the fact that the set of positive semidefinite matrix-valued functions is closed under sums, point-wise limits and element-wise products with symmetric positive semidefinite matrices.  $\Box$ 

*Proof of Theorem [3.4.](#page-21-0)* From [Emery et al.](#page-30-7) [\[2022,](#page-30-7) Equations (28)-(30) and Theorem 3],  $\mathcal{M}_p$  has a representation of the form [\(31\)](#page-19-1) with  $dF_{ij}(\xi)$  =  $R_{ij}(\xi)d\xi$ , where  $[R_{ij}(\xi)]_{i,j=1}^p$  is positive semidefinite under the stated conditions (A) or (B). The theorem thus results from the application of Theorem [3.2.](#page-19-0)  $\Box$  *Proof of Theorem [3.5.](#page-21-1)* Using formula 3.381.4 of [Gradshteyn and Ryzhik](#page-30-8) [\[2007\]](#page-30-8), one can write

$$
\boldsymbol{C}_p(\mathbf{D}) = \left[ \frac{\sigma_{ij}\beta_{ij}^{\nu}}{\Gamma(\nu)} \int_0^{+\infty} \xi^{\nu-1} \exp(-\beta_{ij}\xi) \exp(-\xi D_{ij}^{\theta}) \mathrm{d}\xi \right]_{i,j=1}^p.
$$

 $\left[\frac{\xi^{\nu-1}}{\Gamma(\nu)}\exp(-\beta_{ij}\xi)\right]_i^p$ The conditional negative semidefiniteness of  $[\beta_{ij}]_{i,j=1}^p$  implies that  $\left[\frac{\xi^{\nu-1}}{\Gamma(\nu)}\right]$ *i,j*=1 is positive semidefinite for any  $\xi \geq 0$  [\[Reams,](#page-30-9) [1999,](#page-30-9) Lemma 2.5]. The theorem results from the application of the Schur product theorem and Theorem [3.2.](#page-19-0)  $\Box$ 

*Proof of Theorem [3.6.](#page-21-2)* One can write [\[Porcu et al.,](#page-30-0) [2018\]](#page-30-0)

$$
\boldsymbol{\mathcal{SG}}_p(\mathbf{D}) = \left[ \frac{\sigma_{ij} 2^{\nu-1} (\alpha_{ij} \beta_{ij})^{\nu/2}}{\mathcal{K}_{\nu} \left( \sqrt{\frac{\beta_{ij}}{\alpha_{ij}}} \right)} \int_0^{+\infty} \xi^{\nu-1} \exp \left( -\frac{1}{4 \alpha_{ij} \xi} - \beta_{ij} \xi \right) \exp(-\xi D_{ij}^{\theta}) d\xi \right]_{i,j=1}^p.
$$

The fact that  $[\alpha_{ij}^{-1}]_{i,j=1}^p$  and  $[\beta_{ij}]_{i,j=1}^p$  are conditionally negative semidefinite implies that

$$
\[ \exp\left(-\frac{1}{4\alpha_{ij}\xi} - \beta_{ij}\xi\right) \]_{i,j=1}^p
$$

is positive semidefinite for any  $\xi \geq 0$ . The theorem results from the application of the Schur product theorem and Theorem [3.2.](#page-19-0)  $\Box$ 

*Proof of Proposition [10.](#page-22-1)* We start with the case  $p = 1$  and observe that, by Bochner's theorem [\[Bochner,](#page-30-10) [1955\]](#page-30-10), a continuous mapping  $C : \mathbb{R}^{m'} \to \mathbb{R}$  is positive semidefinite if and only if

$$
C(\boldsymbol{x}) = \int_{\mathbb{R}^{m'}} \exp(i\boldsymbol{x}^\top \boldsymbol{\omega}) G(\mathrm{d}\boldsymbol{\omega}), \qquad \boldsymbol{x} \in \mathbb{R}^{m'},
$$

for *G* being a non-decreasing and bounded measure in R *<sup>m</sup>*. Here, i denotes the unit complex number. Using the above representation, [Cambanis et al.](#page-30-1) [\[1983\]](#page-30-1) show that a mapping  $K : [0, +\infty) \to \mathbb{R}$  belongs to the class  $\Phi_m^1$  if and only if Equation  $(37)$  holds for  $p = 1$  and for *F* being non-decreasing and bounded. In particular, choosing a Dirac measure for *F*, one finds that  $t \mapsto \omega_{m'}(rt)$  belongs to  $\Phi_m^1$  for any  $r \geq 0$ , that is,  $\omega_{m'}(rd_M(\cdot,\cdot))$  is positive semidefinite on R *m*′ .

We now address the general case with  $p \geq 1$ . First, consider a matrixvalued mapping **K** belonging to the class  $\Phi_m^p$ . We invoke the extension of Bochner's theorem to the *p*-variate case [\[Cramer,](#page-31-0) [1940\]](#page-31-0), for which a continuous mapping  $\mathbf{C} : \mathbb{R}^{m'} \to \mathbb{R}^{p \times p}$  is positive semidefinite if and only if

$$
\mathbf{C}(\boldsymbol{x}) = \int_{\mathbb{R}^{m'}} \exp(i\boldsymbol{x}^\top \boldsymbol{\omega}) \mathbf{G}(\mathrm{d}\boldsymbol{\omega}), \qquad \boldsymbol{x} \in \mathbb{R}^{m'},
$$

for **G** a bounded complex Hermitian matrix-valued measure. Hence, the same calculations as much as in [Cambanis et al.](#page-30-1) [\[1983\]](#page-30-1) show that the representation [\(37\)](#page-22-3) holds for a bounded symmetric real matrix-valued measure **F** (that **F** is bounded stems from the fact that  $\mathbf{K}(0)$  is finite). To finish this part of the proof we need to show that  $d\mathbf{F}(r)$  is positive semidefinite for any  $r \geq 0$ , which happens if and only if the mapping

$$
H_{\mathbf{c}}(r) := \mathbf{c}^{\top} \mathbf{F}(\mathrm{d}r) \mathbf{c}, \quad r \in [0, +\infty),
$$

is non-negative for any arbitrary  $c \in \mathbb{R}^p$ . To this end, consider a *p*-variate random field  $\boldsymbol{Z}$  in  $\mathbb{R}^{m'}$  with isotropic covariance **K**, and define  $Z_c := \boldsymbol{c}^\top \boldsymbol{Z}$ , which is a univariate random field with isotropic covariance  $K_c = c^{\top}$ **Kc**. Hence,  $K_c$  obeys to the representation provided by [Cambanis et al.](#page-30-1) [\[1983\]](#page-30-1), with a measure  $F_c$  such that

$$
F_{\mathbf{c}} = \mathbf{c}^{\top} \mathbf{F} \mathbf{c}.
$$

This proves the sufficiency part of the theorem by noting that  $F_c$  is nondecreasing.

Reciprocally, assume that the representation [\(37\)](#page-22-3) holds with a bounded symmetric matrix-valued measure **F** such that  $d\mathbf{F}(r)$  is positive semidefinite for any  $r \geq 0$ . Being positive semidefinite on  $\mathbb{R}^{m'}$  for any  $r \geq 0$ ,  $\omega_{m'}(rd_M(\cdot,\cdot))$ is the covariance function of a univariate Gaussian random field  $Z_r$  on  $\mathbb{R}^{m'}$ . Accordingly, the matrix-valued mapping  $\omega_{m'}(rd_M(\cdot,\cdot))\mathbf{1}_{p\times p}$  belongs to  $\Phi_m^p$  as the covariance function of  $Z_r \mathbf{1}_p$ , and so do the mappings  $\omega_{m'}(r d_M(\cdot, \cdot))d\mathbf{F}(r)$ and  $\mathbf{K}(d_M(\cdot,\cdot))$  owing to the fact that the set of positive semidefinite functions is closed under sums, element-wise products, and pointwise limits.

 $\Box$ 

*Proof of Proposition [11.](#page-23-0)* We provide a proof by direct construction. Let *m*′ be a positive integer. Arguments in Theorem 2.1 of [Gneiting](#page-30-2) [\[1998\]](#page-30-2) provide the identity

$$
\omega_{m'}(t) = \kappa_{m'} I^{(m'-1)} \Omega_{2m'-1}(t), \qquad t \ge 0,
$$
\n(54)

for  $\kappa_{m'}$  a strictly positive constant. Hence, the proof comes from the integral representation [\(37\)](#page-22-3) in concert with a straight use of Fubini's theorem.  $\Box$  *Proof of Proposition [12.](#page-24-0)* The results comes from a straight application of Proposition 2 in [Emery and Porcu](#page-30-4) [\[2023\]](#page-30-4) in concert with Lemma [4.1,](#page-23-1) Proposition [11](#page-23-0) and Fubini's theorem.  $\Box$ 

<span id="page-51-1"></span>Figure 5: An example of graph for which the distance  $D_{11}(v_1, v_3) \not\leq$  $D_{12}(v_1, v_3)$ , for  $p \geq 3$  and  $\alpha$  wisely chosen.

# <span id="page-51-0"></span>**B A Worked Example**

Here we provide a simple example of the multivariate distance properties.

*Example.* Let  $p \geq 3$  and  $\alpha > 0$ . Consider the graph depicted in Figure [5](#page-51-1) with  $V := \{v_1, v_2, v_3\}$  and whose Laplacian matrix **L** and  $\Sigma = L^{-}$  are

$$
\mathbf{L} = \begin{bmatrix} 1 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 1 \end{bmatrix}, \qquad \mathbf{\Sigma} = \frac{1}{9} \begin{bmatrix} 5 & -1 & -4 \\ -1 & 2 & -1 \\ -4 & -1 & 5 \end{bmatrix}.
$$

In addition, the eigendecomposition  $\boldsymbol{\Sigma} = \mathbf{W} \boldsymbol{\Lambda} \mathbf{W}^\top$  is

$$
\mathbf{W} = \begin{bmatrix} -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{6}} & \frac{1}{\sqrt{3}} \\ 0 & -\frac{2}{\sqrt{6}} & \frac{1}{\sqrt{3}} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{6}} & \frac{1}{\sqrt{3}} \end{bmatrix}, \qquad \mathbf{\Lambda} = \begin{bmatrix} 1 & & \\ & \frac{1}{3} & \\ & & 0 \end{bmatrix}.
$$

Let us consider the distance between  $v_1$  and  $v_3$  for the same variable and for different variables, *i.e.*  $D_{11}(v_1, v_3)$  and  $D_{12}(v_1, v_3)$ . Since both  $v_1$  and  $v_3$  are vertices, the contribution of  $\boldsymbol{Z}_E$  is null, therefore, by Equation [\(29\)](#page-16-4), we have:

$$
D_{11}(v_1, v_3) = (\delta_{1,V} - \delta_{3,V})^{\top} \tilde{\Sigma} (\delta_{1,V} - \delta_{3,V})
$$
  
\n
$$
= [1, 0, -1] \tilde{\Sigma} \begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix}
$$
  
\n
$$
= \tilde{\Sigma}_{11} + \tilde{\Sigma}_{33} - 2\tilde{\Sigma}_{13}
$$
  
\n
$$
= \Sigma_{11} + \Sigma_{33} - 2\Sigma_{13} = 2,
$$
  
\n
$$
D_{12}(v_1, v_3) = \delta_{1,V}^{\top} \tilde{\Sigma} \delta_{1,V} + \delta_{3,V}^{\top} \tilde{\Sigma} \delta_{3,V} - 2\delta_{1,V}^{\top} \tilde{\mathbf{X}} \delta_{3,V}
$$
  
\n
$$
= \tilde{\Sigma}_{11} + \tilde{\Sigma}_{33} - 2\tilde{X}_{13}
$$
  
\n
$$
= \Sigma_{11} + \Sigma_{33} + 2k_1 - 2X_{13} - 2k_2
$$
  
\n
$$
= \frac{10}{9} - 2 \cdot \frac{1}{3\alpha p(p-1)} - 2X_{13}.
$$

Now it is possible to compute  $X_{13}$  by means of Equation [\(20\)](#page-14-4):

$$
X_{13} = \frac{1}{2\alpha(p-1)} W_{1\star} \left( \alpha(p-2)\mathbf{\Lambda} + \sqrt{\mathbf{I}_n - \mathbf{J}_n - 2\alpha(p-2)\mathbf{\Lambda} + \alpha^2 p^2 \mathbf{\Lambda}^2} - \mathbf{I}_n - \mathbf{J}_n \right) W_{\star 3}^\top
$$
  
\n
$$
= \frac{1}{2\alpha(p-1)} \sum_{i=1}^3 W_{1i} W_{3i} \left( \alpha(p-2)\mathbf{\Lambda} + \sqrt{\mathbf{I}_n - \mathbf{J}_n - 2\alpha(p-2)\mathbf{\Lambda} + \alpha^2 p^2 \mathbf{\Lambda}^2} - \mathbf{I}_n - \mathbf{J}_n \right)_{ii}
$$
  
\n
$$
= \frac{1}{2\alpha(p-1)} \left( -\frac{1}{2} \left( \alpha(p-2) \cdot 1 + \sqrt{1 - 2\alpha(p-2) \cdot 1 + \alpha^2 p^2 \cdot 1^2} - 1 \right) + \frac{1}{6} \left( \alpha(p-2) \cdot \frac{1}{3} + \sqrt{1 - 2\alpha(p-2) \cdot \frac{1}{3} + \alpha^2 p^2 \cdot \frac{1}{3^2}} - 1 \right) + \frac{1}{3} \left( \alpha(p-2) \cdot 0 + \sqrt{0 - 2\alpha(p-2) \cdot 0 + \alpha^2 p^2 \cdot 0^2} - 2 \right) \right)
$$
  
\n
$$
= \frac{1}{2\alpha(p-1)} \left( -\frac{1}{2} \sqrt{1 - 2\alpha(p-2) + \alpha^2 p^2} + \frac{1}{6} \sqrt{1 - \frac{2}{3} \alpha(p-2) + \frac{\alpha^2 p^2}{9} - \frac{4}{9} \alpha(p-2) - \frac{1}{3}} \right).
$$

With  $p = 3$ , the maximum discrepancy  $d(\alpha) := D_{11}(v_1, v_3) - D_{12}(v_1, v_3)$  is

reached at  $\alpha^* = 1.32092$ . In such a case,  $X_{13} = -0.48598$  and thus:

$$
D_{12}(v_1, v_3) = \frac{10}{9} - 2 \cdot \frac{1}{18 \cdot 1.32092} - 2 \cdot (-0.48598) = 1.99896 < 2 = D_{11}(v_1, v_3),
$$

that is,  $d(\alpha^*) = 0.00103$ . Notice that for  $\alpha := \hat{\alpha} = 0.97222$  and for  $\alpha \to +\infty$ , we achieve  $d(\hat{\alpha}) = 0$ , and for  $0 < \alpha < \hat{\alpha}$  we have  $d(\alpha) < 0$ . One can obtain larger values for  $d(\alpha)$  by taking  $\alpha := \frac{1}{p}$  and letting  $p \to +\infty$ . In this setting, we have  $X_{13} \to -\frac{1}{3}$  and  $d(\alpha) \to \frac{2}{9}$ .
