Abstract

Introduction: Generative Artificial Intelligence, particularly large language models (LLMs), offers transformative potential for Health Economics and Outcomes Research (HEOR). However, evaluating the quality, transparency, and rigor of LLM-assisted research lacks standardized guidance. This article introduces the ELEVATE-AI LLMs framework and checklist, designed to support researchers and reviewers in assessing LLM use in HEOR.

Methods: The ELEVATE-AI LLMs framework was developed through a targeted review of existing guidelines and evaluation frameworks. The framework comprises ten evaluation domains, including model characteristics, accuracy, comprehensiveness, and fairness. The accompanying checklist operationalizes the framework. To validate the framework, we applied it to two published studies, demonstrating its usability across different HEOR tasks.

Results: The ELEVATE-AI LLMs framework provides a comprehensive structure for evaluating LLM-assisted research, while the checklist facilitates practical application. Validation of the framework and checklist on studies of systematic literature reviews and health economic modeling highlighted their ability to identify strengths and gaps in reporting.

Limitations: While the ELEVATE-AI LLMs framework provides robust guidance, its broader generalizability and applicability to diverse HEOR tasks require further empirical testing. Additionally, several metrics adapted from computer science, need further validation in HEOR contexts.

Conclusion: The ELEVATE-AI LLMs framework and checklist fill a critical gap in HEOR by offering structured guidance for evaluating LLM-assisted research. By promoting transparency, accuracy, and reproducibility, they aim to standardize and improve the integration of LLMs into HEOR, ensuring their outputs meet the field's rigorous standards.

The ELEVATE-AI LLMs Framework: An Evaluation Framework for Use of Large Language Models in HEOR: an ISPOR Working Group Report

Introduction

Generative Artificial Intelligence (AI), particularly foundation models including Large Language Models (LLMs), is poised to transform Health Economics and Outcomes Research (HEOR) by streamlining traditionally labor-intensive tasks¹. Health Technology Assessment (HTA) bodies have already begun addressing the implications of using generative AI in their evaluation processes. For instance, the National Institute for Health and Care Excellence (NICE) in the UK has issued a Statement of Intent ² to describe their approach to AI in general as well as a position statement that covers the principles that should be adhered to when generative AI is used in submissions ³. Despite its transformative potential, the use of generative AI in scientific endeavors presents challenges that demand rigorous and structured evaluation frameworks tailored to HEOR applications.

The evolution of AI over the past decade, marked by the emergence of foundation models trained on vast datasets through self-supervised learning, has shifted the paradigm from task-specific systems to versatile, multi-purpose tools ^{4,5}. The release of ChatGPT in late 2022 popularized user-friendly interfaces for LLMs, making advanced AI accessible to researchers and practitioners across various fields, including HEOR ^{1,6}. Examples of widely available foundation models include Google's Gemini, OpenAI's GPT series, Anthropic's Claude, and Meta's Llama ⁴. Increasingly, these models are multimodal, capable of processing data beyond text, such as images, videos, and audio, while retaining their foundation as LLMs.

Within HEOR, LLMs are already demonstrating their potential to enhance systematic literature reviews (SLRs), health economic modeling (HEM), and real-world evidence (RWE) generation. In SLRs, LLMs can assist with abstract and full-text screening, bias assessment, data extraction, and automating meta-analysis code, accelerating evidence synthesis ⁷⁻¹⁷. For HEM, foundation models can replicate existing frameworks, generate de novo models, validate assumptions, and adapt outputs for diverse populations or platforms, improving efficiency and scalability ¹⁸⁻²¹. In RWE generation, LLMs facilitate the integration of unstructured electronic health record (EHR)

data into analyzable datasets, enabling researchers to draw insights from multimodal sources such as genomics and imaging ²²⁻²⁹. While these applications offer significant promise, challenges such as hallucinations, data inaccuracies, and the need for human oversight underscore the importance of robust evaluation standards ¹.

This article, developed by the ISPOR Working Group on Generative AI, introduces the ELEVATE-AI LLMs framework: an Evaluation Framework for Use of Large Language Models focused on Evidence, Transparency, and Efficiency. The framework provides structured criteria for evaluating LLM-generated outputs in HEOR research, emphasizing accuracy, transparency, and reproducibility. Designed to support both researchers and reviewers, ELEVATE-AI LLMs aims to standardize reporting practices and ensure the quality of AI-augmented studies. The framework was validated using two distinct use cases—one in SLR and one in HEM—illustrating how it can guide the integration of generative AI into HEOR while maintaining scientific rigor.

Methods

The ELEVATE-AI LLMs framework was developed through a multi-step process combining a targeted literature review, iterative framework development, and validation through application to published studies. To inform the framework development, we conducted a targeted review of guidelines, frameworks, and reporting standards related to artificial intelligence (AI) and large language models (LLMs) in healthcare and HEOR. This exploratory review focused on foundational principles and methodologies from fields such as machine learning, systematic reviews, and health technology assessment (HTA). While not a systematic review, it captured key insights to guide framework design. We prioritized widely cited frameworks, including, HELM³⁰, and PALISADE³¹, as well as emerging AI-specific guidelines like PRISMA-AI³², TRIPOD+AI³³, and RAISE³⁴. Literature was identified through PubMed searches using AI- and HEOR-relevant keywords, supplemented by references from key papers and the authors' expertise. Although limited in scope, the review provided a robust foundation for adapting general principles to HEOR applications.

Using findings from the literature review, we identified and defined key evaluation domains relevant to LLM applications in HEOR. Reporting guidelines were developed to ensure the framework's applicability across diverse HEOR tasks, such as SLRs and HEM The framework

was validated by applying it to two published studies: systematic literature review (Robinson et al.) ¹⁴ and health economic modeling (Reason et al.) ²¹. These worked examples demonstrated the framework's utility in evaluating LLM-generated outputs, identifying both strengths and gaps in reporting across its domains.

Results

Review of Existing Frameworks for Evaluating LLMs

A range of regulations and guidelines has emerged to ensure the responsible use of AI, including foundation models and LLMs, in healthcare and research. These frameworks address risk management, transparency, and compliance with legal standards, aiming to mitigate risks such as bias, privacy violations, and safety concerns while fostering innovation. However, most frameworks are general and not specifically tailored to HEOR use cases, highlighting the need for a dedicated evaluation framework like ELEVATE-AI LLMs.

Broad guidelines and frameworks, such as the White House Executive Order on AI³⁵ and the NIST AI Risk Management Framework^{36,37}, emphasize transparency, accountability, and risk assessment across AI systems. While not specific to HEOR, they provide foundational guidance for evaluating AI, including LLMs, in healthcare. In contrast, healthcare-specific frameworks, such as those from the World Health Organization (WHO) and the National Academy of Medicine (NAM), offer ethical guidelines for AI deployment in clinical and research settings, stressing equity, bias mitigation, and privacy protection³⁸⁻⁴⁰. Regulatory agencies have also begun addressing AI in healthcare. The European Medicines Agency (EMA) and the U.S. Food and Drug Administration (FDA) have issued guidance for AI applications across the drug development lifecycle, focusing on transparency, data quality, and lifecycle management ^{41,42,43,44}. The National Institute for Health and Care Excellence (NICE) in the UK has recently issued a Statement of Intent and a position statement on AI in evidence generation ^{2,3}, emphasizing validation, bias detection, and data integrity. However, most HTA bodies have yet to develop specific guidelines for AI in HEOR¹.

Frameworks from computer science and biomedical informatics, such as the Holistic Evaluation of Language Models (HELM)³⁰, offer multi-dimensional approaches to evaluating AI systems, emphasizing metrics like accuracy, robustness, and fairness. Similarly, the framework by Bedi et

al.⁴⁵ adapts these principles for healthcare, focusing on transparency, equity, and rigorous validation. These frameworks provide critical insights into the evaluation of AI models, including LLMs, for HEOR tasks. In addition, published reporting guidelines inform the development of HEOR-specific frameworks. The PALISADE Checklist³¹ highlights transparency and accountability in AI and machine learning (ML) applications, addressing key elements such as algorithm purpose, resource requirements, reproducibility, and explainability. The TRIPOD+AI³³ statement provides a 27-item checklist for reporting clinical prediction models, prioritizing transparency and rigorous documentation. Emerging guidelines, such as PRISMA-AI³² and RAISE³⁴, focus on integrating AI tools into systematic reviews, ensuring transparency, reproducibility, and ethical use in evidence synthesis. The REFORMS checklist⁴⁶, while not specific to generative AI, outlines principles for reporting machine learning studies, offering insights into reproducibility and model performance. Collectively, these frameworks and guidelines provide a foundation for addressing the challenges and opportunities presented by LLMs in healthcare and HEOR. They have directly informed the development of the ELEVATE-AI LLMs framework, which adapts these principles to evaluate LLMs in HEOR tasks such as SLRs and HEM.

The ELEVATE-AI LLMs Framework and Checklist:

The ELEVATE-AI LLMs framework is designed to guide the evaluation of HEOR research involving LLMs by focusing on both the foundational characteristics of the models and the quality of their outputs (**Figure 1**). Adapted from the HELM and Bedi et al.'s frameworks ^{30,45}, the ELEVATE-AI LLMs framework has been tailored specifically for HEOR applications (**Table 1**). While retaining the core domains proposed by Bedi et al., two additional domains— Model Characteristics and Reproducibility Protocols and Generalizability—were introduced to address the unique requirements of HEOR research. ELEVATE-AI LLMs includes reporting guidelines for each domain, ensuring transparency, reproducibility, and applicability across various HEOR applications (e.g., SLRs, HEM, RWE generation) and their sub-tasks (e.g., abstract screening, meta-analyses, model structure development, parameter estimation). Below, we describe briefly each of the 10 proposed domains. Each domain is also assigned a level of maturity: a high level of maturity indicates that the metrics needed for this domain are available, while a low level of maturity highlights the need for further work to identify appropriate metrics, which may vary depending on the specific task (e.g., abstract screening might require different metrics than health state identification in a HEM). The accompanying checklist is presented in **Table 2**.

Figure 1: The ELEVATE-AI LLM Framework

Table 1: An Evaluation Framework for Large-language models focused on Evidence,Transparency, and Efficiency (The ELEVATE-AI LLMs Framework) (adapted fromHELM and Bedi et al.)

Domain Name	Domain Description	Reporting Guidelines	Level of Maturity of Domain Measurement
Model Characteristics	Describes the model's foundational characteristics, such as name, version, developer, model access, license, release date, architecture, training data, and fine- tuning performed for specific tasks.	 Provide details of the model, including name, version, developer(s), release date, license (e.g. commercial or open-source), access (e.g., links to the models), architecture (e.g., transformer-based). Describe training data, including domain-specific sources (e.g., PubMed) and any fine-tuning performed. 	High

Accuracy Assessment	Measures how closely the model's output aligns with the correct or expected answer, evaluating precision, relevance, and correctness.	 Compare results against human benchmarks or gold-standard datasets for validation. If appropriate for the task at hand, report metrics (e.g., Precision, Recall, F1 Score, AUC). These metrics will not be applicable to all tasks. 	Medium – further work required on adapting AI/ML metrics to HEOR studies and identifying appropriate metrics for specific tasks.
Comprehensiveness Assessment	Assesses how thoroughly the model's output addresses all aspects of the task, ensuring completeness, coherence, and critical coverage.	 Evaluate completeness by comparing outputs to benchmarks, such as published reviews or models. Use expert evaluations to confirm critical elements are addressed. 	High
Factuality Verification	Evaluates whether the model's output is accurate and based on verifiable sources, identifying hallucinated or non- existent citations.	 Explain methods to verify factual accuracy (e.g., expert review, source validation). Document discrepancies and corrective actions taken. 	High
Reproducibility Protocols and Generalizability	Ensures methods and outputs can be independently verified by documenting workflows, sharing code, and specifying hyperparameters. Evaluates generalizability of approach proposed	 List reproducibility protocols, including training code, query phrasing, and hyperparameters. Share workflows to facilitate independent verification. Address generalizability of methods to similar research questions 	High
Robustness Checks	Tests the model's resilience to input variations, such as typographical errors or ambiguous queries.	 Document robustness tests, including handling of typos, adversarial inputs, or ambiguous phrasing. Report any changes in performance under these conditions. 	High
Fairness and Bias Monitoring	Evaluates whether the model's output is equitableand free from harmful biases or stereotypes across diverse groups and contexts.	 Monitor fairness by checking for bias in outputs related to gender, age, ethnicity, or other demographics. If appropriate, use fairness metrics like demographic parity and document corrective actions if biases are identified. 	Low – the use of metrics to assess fairness and bias is an ongoing area of research
Deployment Context and Efficiency Metrics	Examines the technical setup, resource requirements, and efficiency metrics to evaluate practical feasibility.	- Describe deployment setup, including hardware (e.g., NVIDIA A100 GPUs) and software (e.g., TensorFlow, PyTorch) and runnable deployment code (e.g., via Docker)	High

Calibration and Uncertainty	Measures how well the model conveys uncertainty in its outputs, including confidence levels and its ability to handle ambiguity appropriately.	 Report efficiency metrics like processing time, scalability, and resource efficiency. If appropriate for the task at hand, describe calibration methods and metrics appropriate for the task (e.g. Expected Calibration Error) Specify thresholds for flagging outputs requiring manual review (e.g. percent of abstracts included in screening in SLR) 	Low – the use of metrics to evaluate calibration and uncertainty is an ongoing area of research
Security and Privacy Measures	Assesses adherence to security, privacy, and data protection standards and regulations, including anonymization, secure handling, and compliance with regulations like GDPR or HIPAA, if appropriate.	 Describe security protocols, such as data encryption, anonymization, and access controls. Ensure compliance with regulations like GDPR or HIPAA if appropriate Document measures to safeguard intellectual property and copyright. 	Low: identifying the appropriate metrics for this domain is an ongoing area of research
Overall Score	Calculates an overall score for the evaluation using the checklist	Assign 3 points for each domain rated as Clearly Reported, 2 points for Ambiguous, and 1 point for Not Reported. Sum the points across all domains to calculate the overall score.	Low: the usefulness of this score will need to be further evaluated through feedback from the HEOR community

AUC = Area under the curve; GDPR = General Data Protection Regulation; GPU = Graphics Processing Unit; LLM = large language model; HIPAA = Health Insurance Portability and Accountability Act;

Model Characteristics: This domain emphasizes documenting the foundational features of the model, including its name, version, developer, release date, access (e.g., links to the models), license (commercial or open-source, re-use restrictions etc.), architecture (e.g., transformer-based), and training data sources. Reporting guidelines require details on training data, including domain-specific sources (e.g., PubMed or proprietary clinical notes) as well as any domain-specific fine-tuning performed to adapt the model for particular tasks. (Level of maturity: high).

Accuracy Assessment: Evaluating the accuracy of a model is essential to understand how closely its outputs align with correct answers. Validation can be achieved through comparisons

against human benchmarks or gold-standard datasets. An ongoing area of work involves reviewing accuracy metrics used in the AI/ML field and establishing whether they can be applied to HEOR tasks. These might include general AI/ML metrics such as precision, recall, F1 Score, and area under the curve (AUC), as well as natural language processing (NLP)-specific metrics (e.g., BLEU) and application-specific metrics (e.g., GREEN for radiology report generation)⁴⁷. Future work will involve proposing metrics tailored to specific HEOR application tasks (e.g., SLRs, HEM, and their sub-tasks). **(Level of maturity: medium).**

Comprehensiveness Assessment: To ensure outputs are comprehensive, the framework assesses whether all aspects of a given task are addressed coherently and completely. Outputs should be compared to benchmark publications and expert review can confirm that critical elements are included. (Level of maturity: high).

Factuality Verification: This domain requires methods to verify the accuracy of outputs (e.g., expert review, source validation) and mandates documentation of any discrepancies or corrective actions taken to address hallucinated or fabricated material, such as citations¹⁷. (Level of maturity: high).

Reproducibility Protocols and Generalizability: Reproducibility is critical in science, ensuring that findings can be independently validated and trusted to inform policy, clinical decision-making, and resource allocation. This domain calls for documenting workflows, training code, query phrasing, and hyperparameters to enable independent verification of findings ^{46,48}. It should be noted that even with current open-source models, hyperparameters may not always be fully available and interpretable. This domain also includes generalizability, assessing whether the proposed approach can be broadly applied. If generative AI tools are too narrowly tailored to a particular problem, their generalizability to other research questions may be limited. **(Level of maturity: high)**

Robustness Checks: This domain evaluates the model's resilience to input variations, such as typographical errors or ambiguous phrasing. Reporting guidelines recommend documenting these tests and reporting any changes in performance under such conditions. (Level of maturity: high).

Fairness and Bias: This domain focuses on monitoring fairness and bias to ensure outputs are equitable and free from harmful biases. It recommends conducting fairness assessments across sociodemographics (e.g., gender, age, ethnicity) and using metrics like demographic parity ⁴⁹⁻⁵¹. As this is still an area of active research, understanding which metrics to use and how to apply them will require some training and development, particularly for applications in the HEOR field. (Level of maturity: low).

Deployment Context and Efficiency Metrics: This domain examines the technical aspects of the model deployment, requiring descriptions of the setup (e.g., hardware like NVIDIA GPUs, software frameworks like TensorFlow or PyTorch, and whether runnable deployment code, such as via Docker, is provided). It also includes metrics such as processing time, scalability, and resource efficiency. For example, time to generate outputs in tasks like SLRs and HEMs is highlighted as an important metric. **(Level of maturity: high).**

Calibration and Uncertainty: This domain ensures that the model conveys confidence levels appropriately and effectively handles ambiguity. Similar to accuracy metrics, ongoing work involves reviewing metrics used in the AI/ML field, such as Expected Calibration Error (ECE),⁵² and determining their applicability to HEOR tasks. For example, setting thresholds for manual review of abstracts is one approach to evaluating uncertainty in abstract and full text screening in SLRs³⁰. These metrics have not yet commonly employed in the HEOR field and will require further development and testing to understand how best to apply them in HEOR use cases. **(Level of maturity: low).**

Security and Privacy: This domain assesses adherence to AI regulations and data protection standards, requiring descriptions of security protocols (e.g., encryption, anonymization, access controls) and compliance with regulations such as GDPR or HIPAA (if appropriate). It also emphasizes measures to safeguard intellectual property and copyright, ensuring trust and integrity in AI research¹. (Level of maturity: low).

Overall Score: A streamlined scoring system rates each domain on a three-point scale: Clearly Reported (3 points), Ambiguous (2 points), or Not Reported (1 point). This standardized approach helps reviewers efficiently assess reporting quality, identifying both strengths and areas for improvement. "Clearly Reported" signifies full adherence to domain criteria, "Ambiguous" reflects partial fulfillment or unclear reporting, and "Not Reported" indicates missing information. The total score is calculated by summing points across all domains, offering a quantitative measure of reporting quality. Higher scores denote more rigorous and transparent reporting, while lower scores highlight areas needing improvement. (Level of maturity: low).

Table 2: ELEVATE-AI LLMs Checklist for Evaluating LLM Use in HEOR Research

Model Characteristics

Is the model's name, version, developer, release date, license (e.g., open-source or commercial), and architecture described?

Are the training data sources (e.g., domain-specific datasets like PubMed) and fine-tuning details provided?

Accuracy Assessment

Are task-specific accuracy metrics (e.g., Precision, Recall, F1 Score) reported, where applicable (accounting for the fact that different metrics will be relevant for different tasks)?

Are outputs validated against human benchmarks or gold-standard datasets?

Comprehensiveness Assessment

Are outputs compared to relevant benchmarks (e.g., published reviews, validated models) to ensure completeness?

Is there expert evaluation confirming all critical elements of the task are addressed?

Factuality Verification

Are methods for verifying the factual accuracy of outputs (e.g., cross-referencing with sources, expert review) described?

Are discrepancies and corrective actions documented?

Reproducibility Protocols and Generalizability

Are reproducibility protocols (e.g., training code, query phrasing, hyperparameters) shared? Are workflows provided to support independent verification?

Is the generalizability of the approach and methods to similar research questions addressed?

Robustness Checks

Are robustness tests (e.g., handling typographical errors, ambiguous queries) documented? Are changes in model performance under these conditions reported?

Fairness and Bias Monitoring

Are outputs evaluated for biases or stereotypes related to gender, age, ethnicity, or other demographics? Are fairness metrics (e.g., demographic parity) used (if applicable), and corrective actions for identified biases documented?

Deployment Context and Efficiency Metrics

Are deployment setup details (e.g., hardware, software, runnable deployment code) clearly described? Are efficiency metrics (e.g., processing time, scalability, resource usage) reported?

Calibration and Uncertainty

Are calibration methods (e.g., Expected Calibration Error) described (if applicable) ? Are thresholds for manual review of outputs (e.g., ambiguous cases flagged in systematic reviews) specified?

Security and Privacy Measures

Are security protocols (e.g., encryption, anonymization, access controls) documented? Is compliance with regulations like GDPR or HIPAA reported, if applicable? Is compliance with intellectual property and copyright law documented ?

Overall Score: Assign 3 points for each domain rated as Clearly Reported, 2 points for Ambiguous, and 1 point for Not Reported. Sum the points across all domains to calculate the overall score.

Applications of the ELEVATE-AI LLMs Framework to HEOR Activities

To demonstrate its utility, the ELEVATE-AI LLMs framework was applied to two key tasks in HEOR: SLR abstract screening for systematic literature reviews and the development of a costeffectiveness model **(Supplemental Material)**. These examples illustrate the framework's flexibility and its ability to guide evaluations across diverse research activities within HEOR. While these tasks highlight specific applications, the ELEVATE-AI LLMs framework is designed to be broadly applicable to a wide range of HEOR tasks involving LLM assistance, extending beyond the examples provided.

Validating the ELEVATE-AI LLMs Framework: Application to two Published Use Cases in HEOR

To validate the checklist and demonstrate its utility, the ELEVATE-AI LLMs framework was applied to two HEOR publications: one focused on SLR abstract screening¹⁴ and the other on health economic modeling for cost-effectiveness analysis²¹. Chat-GPT 4.0 was used to produce a first draft of the evaluation, the prompt is provided in Box 1. Careful review and editing of AI - generated output was conducted by the authors. **Tables 3 and 4** illustrate how the framework systematically assesses LLMs for these applications and show its adaptability to different HEOR tasks.

Application to a SLR Publication:

Table 3 shows the application of the ELEVATE-AI LLMs framework to evaluate the Bio-SIEVE model in the SLR study by Robinson et al.¹⁴. This study investigates the use of LLMs to automate title and abstract screening for SLR in the biomedical field and assesses the performance of LLMs in exclusion reasoning, (i.e., providing the rationale for excluding an abstract). The model, instruction-tuned on LLaMA and Guanaco, uses a 7B parameter architecture with quantization (4-bit LoRA) and was trained on 7,330 Cochrane systematic reviews, focusing on inclusion/exclusion criteria. Fine-tuning was validated with a curated safety-first test set to ensure task-specific performance. Accuracy metrics such as precision, recall, and overall accuracy demonstrated superior performance compared to logistic regression and other LLMs (e.g., ChatGPT). Comprehensiveness was validated against gold-standard datasets and expert reviews to ensure no relevant abstracts were missed. Factuality verification involved cross-checking inclusion/exclusion decisions with expert datasets, with discrepancies documented and addressed. Reproducibility protocols included detailed documentation of finetuning parameters and workflows, with publicly available code and weights for independent validation. The methods are likely generalizable to other medical domains. Robustness was assessed by varying input prompts, with Bio-SIEVE consistently excluding irrelevant abstracts. Fairness and bias monitoring were not explicitly measured. Deployment metrics, including hardware specifications (e.g., 4 A100 GPUs) and processing time (e.g., 1.39 seconds per sample), highlighted scalability. Calibration and uncertainty measures were limited, relying on manual validation without explicit thresholds for ambiguous cases. Security and privacy were addressed through anonymization and secure handling of Cochrane data, but copyright protection was not discussed. Compliance with HIPAA or GDPR would not be relevant to this type of study.

In summary, the application of Bio-SIEVE study by Robinson et al. ¹⁴ found that 6 domains were "clearly reported", 2 were "ambiguous" and 2 were "not reported". As expected, three out of the four domains that were evaluated as ambiguous or not reported (Fairness and Bias Monitoring, Calibration and Uncertainty, Security and Privacy Measures) correspond to domains with a low level of maturity for metrics, further highlighting the need for future work to identify the useful metrics for these domains.

Table 3: Application of the ELEVATE-AI LLMs Checklist to a Systematic Literature Review Study (Robinson et al.)¹⁴

Checklist Questions	Domain Assessment
1. Model Characteristics	Clearly Reported
Is the model's name, version, developer, release date,	The Bio-SIEVE model is based on instruction-tuned
license (e.g., open-source or commercial), and	versions of LLaMA7B and Guanaco7B, using a 7B
architecture described?	parameter architecture with quantization (4-bit). BIO-
Are the training data sources (e.g., domain-specific	SIEVE is not open-source, although several elements
datasets like PubMed) and fine-tuning details	(e.g., code, parameters) are provided. The publication
provided?	date is 2023. Training involved 7,330 systematic

2. Accuracy Assessment Are task specific accuracy metrics (e.g., Precision, Recall, F1 Score) reported where applicable (accounting for the fact that different metrics will be relevant for different tasks)? Are outputs validated against human benchmarks or gold-standard datasets?	reviews from Cochrane, focusing on inclusion/exclusion criteria and reasoning for abstract exclusion. Instruction fine-tuning was conducted to improve performance on systematic review tasks. Clearly Reported The paper reports precision, recall, and accuracy metrics for inclusion/exclusion tasks, comparing Bio- SIEVE's performance to baseline models (e.g., logistic regression) and other LLMs like ChatGPT. Bio-SIEVE achieved higher recall and accuracy for inclusion/exclusion but underperformed in exclusion reasoning, where ChatGPT demonstrated better results.
3. Comprehensiveness Assessment Are outputs compared to relevant benchmarks (e.g., published reviews, validated models) to ensure completeness? Is there expert evaluation confirming all critical elements of the task are addressed?	Clearly Reported Bio-SIEVE's outputs were validated against gold- standard datasets (e.g., Cochrane) and expert-annotated safety-first subsets. The Bio-SIEVE Guanaco7B (Single) achieved a precision of 0.85 and a recall of 0.82 on the test set, demonstrating a strong balance between minimizing false positives and capturing relevant abstracts (but performed less well on the safety-first subset). Expert validation confirmed no critical gaps in inclusion, aligning with the goal of capturing all potentially relevant abstracts during screening
4. Factuality Verification Are methods for verifying the factual accuracy of outputs (e.g., cross-referencing with sources, expert review) described? Are discrepancies and corrective actions documented?	Clearly Reported Exclusion reasoning and inclusion/exclusion decisions were cross-referenced with expert-annotated datasets. Discrepancies (e.g. missed inclusions) were documented and analyzed, with manual reviews of ambiguous cases ensuring factual reliability.
 5. Reproducibility Protocols and Generalizability Are reproducibility protocols (e.g., training code, query phrasing, hyperparameters) shared? Are workflows provided to support independent verification? Is the generalizability of the approach and methods to similar research questions addressed? 6. Robustness Checks 	Clearly ReportedDetailed reproducibility information includes fine- tuning parameters (e.g., batch size, learning rate), pre- processing workflows, and access to training datasets.Access to code and adapter weights is provided on HuggingFace. The approach is generalizable to abstract screening tasks in other medical domains.Clearly Reported
Are robustness tests (e.g., handling typographical errors, ambiguous queries) documented? Are changes in model performance under these conditions reported?	Robustness was tested by varying input prompts and testing irrelevancy exclusions (e.g. pairing abstracts with unrelated topics). Bio-SIEVE consistently excluded irrelevant abstracts, demonstrating robustness to input variations.
7. Fairness and Bias Monitoring Are outputs evaluated for biases or stereotypes related to gender, age, ethnicity, or other demographics? Are fairness metrics (e.g., demographic parity) used (if applicable), and corrective actions for identified biases documented?	Not Reported Fairness metrics, such as demographic parity, or bias in inclusion/exclusion decisions, were not explicitly assessed. Population biases were not evaluated.

8. Deployment Context and Metrics	Ambiguous
Are deployment setup details (e.g., hardware, software, runnable deployment code) clearly described? Are efficiency metrics (e.g., processing time,	The Bio-SIEVE Guanaco7B models were trained on 4 NVIDIA A100 80GB GPUs for 24-40 hours, depending on the model. Inference time was reported
scalability, resource usage) reported?	as 1.39 seconds per sample on an RTX 3090 GPU, but context (e.g., batch size) and memory usage metrics were not provided.
9. Calibration and Uncertainty	Ambiguous
Is the model's uncertainty quantified and explicitly reported (if applicable)? Are thresholds for manual review of outputs (e.g., ambiguous cases flagged in systematic reviews) specified?	Confidence in inclusion/exclusion decisions was not explicitly quantified. Manual validation of safety-first decisions suggests effective uncertainty management, but explicit thresholds were not defined.
10. Security and Privacy Measures	Not Reported
Are security protocols (e.g., encryption, anonymization, access controls) documented? Is compliance with regulations like GDPR or HIPAA reported, if applicable? Is compliance with intellectual property and copyright law documented ?	Compliance with AI regulations, copyright protection, and data security were not discussed. Patient-level data was not used, minimizing direct privacy risks.
Overall Score: Assign 3 points for each domain rated as Clearly Reported, 2 points for Ambiguous, and 1 point for Not Reported. Sum the points across all domains to calculate the overall score.	Clearly Reported: 6, Ambiguous: 2, Not Reported: 2 Total Score = 24/30

GPU = Graphics Processing Unit; LLM = Large Language Model

Application to a Health Economic Modeling Publication:

Table 4 demonstrates the application of the ELEVATE-AI LLMs framework to a health economic modeling study by Reason et al. ²¹. The study explores the feasibility of using GPT-4 to automatically program health economic models. Specifically, the study aims to replicate two existing health economic analyses: the cost-effectiveness of nivolumab versus docetaxel for non-small cell lung cancer (NSCLC) and nivolumab plus ipilimumab versus sunitinib and pazopanib for renal cell carcinoma (RCC). The authors provided a detailed description of GPT-4, the LLM used in their study. Accuracy was demonstrated by replicating published three-state models (progression-free, progressed disease, and death states) with outputs aligning closely to benchmark results, as assessed by comparing incremental cost-effectiveness ratios (ICERs) to published values. For NSCLC models, 93% of runs were error-free, while RCC models required simplification but still achieved accuracy within 1% of published ICERs. Precision and recall metrics are not applicable to this use case. Comprehensiveness was validated through benchmarking and replication of complete models, though the need to simplify complex RCC

calculations highlighted some limitations. Factuality verification cross-referenced ICERs and transition values with published sources, with minor discrepancies attributed to differences in discounting methods. Reproducibility was supported by detailed prompts, API parameters, and automation workflows, with generated R scripts made publicly available. Generalizability was not discussed. Robustness was tested by varying prompts, revealing limitations in handling atypical scenarios, such as overly complex calculations for RCC. Fairness was not explicitly addressed, as the study focused on technical replication rather than equity considerations. Deployment relied on Python and R scripts processed on mid-range GPUs, with generation times averaging 715 seconds for NSCLC and 956 seconds for RCC. Scalability was improved through automation workflows. Calibration and uncertainty were evaluated qualitatively, with minor ICER variability noted across runs. Security and privacy were addressed by using dummy data to replace sensitive inputs, and the authors suggested private LLM instances as a future solution to enhance security and intellectual property protections.

The health economic modeling study by Reason et al. ²¹ effectively demonstrated the use of LLMs in cost-effectiveness modeling but omitted information required for several domains in the ELEVATE-AI LLMs framework. The evaluation found that 6 domains were "clearly reported", 2 were "ambiguous" and 2 were "not reported". Two out of the four domains that were evaluated as ambiguous or not reported (Fairness and Bias Monitoring, Calibration and Uncertainty) correspond to domains with a low level of maturity for metrics. Two of the domains, Model Characteristics and Reproducibility Protocols and Generalizability were evaluated as Ambiguous, but it would not be difficult for the authors in further iterations to report the appropriate information for these domains, indicating why the ELEVATE-AI LLMs framework has an important role to play in standardizing what authors might report.

 Table 4: Application of the ELEVATE-AI LLMs Checklist to a Health Economic Modeling

 Study (Reason et al.) ²¹

Checklist Questions	Domain Assessment
1. Model Characteristics	Ambiguous
Is the model's name, version, developer, release date,	The study utilized GPT-4, a transformer-based large
license (e.g., open-source or commercial), and	language model developed by OpenAI, a commercial
architecture described?	model. Specific GPT-4 model release date was not
Are the training data sources (e.g., domain-specific	specified. The model was accessed via API, and no
datasets like PubMed) and fine-tuning details	specific fine-tuning for health economic modeling was
provided?	reported.

2. Accuracy Assessment Are task specific accuracy metrics (e.g., Precision, Recall, F1 Score) reported where applicable (accounting for the fact that different metrics will be relevant for different tasks)?? Are outputs validated against human benchmarks or gold-standard datasets?	 GPT-4 training data includes general-purpose datasets. Explicit adaptation for health economic modeling tasks was absent. In this study, domain-specific functionality was achieved through iterative development of contextual prompts. Clearly Reported Accuracy was assessed by comparing model outputs to the published model results. For NSCLC, 93% of runs were completely error-free; for RCC, 60% of runs required simplification but were error-free. ICERs were within 1% of published values.
3. Comprehensiveness Assessment Are outputs compared to relevant benchmarks (e.g., published reviews, validated models) to ensure completeness? Is there expert evaluation confirming all critical elements of the task are addressed?	Clearly Reported Outputs replicated complete three-state models, including progression-free, progressed disease, and death states. Simplification of complex RCC model steps was noted. Benchmarking against published results ensured alignment.
4. Factuality Verification Are methods for verifying the factual accuracy of outputs (e.g., cross-referencing with sources, expert review) described? Are discrepancies and corrective actions documented?	Clearly Reported ICERs and transition values were cross-referenced with published models. Minor discrepancies (e.g., discounting assumptions) were documented and attributed to differences in software calculation methods.
5. Reproducibility Protocols and Generalizability Are reproducibility protocols (e.g., training code, query phrasing, hyperparameters) shared? Are workflows provided to support independent verification? Is the generalizability of the approach methods to similar research questions addressed?	Ambiguous Prompts, API parameters, and Python-based automation workflows were described, enabling reproducibility. Generated R scripts are publicly available for independent validation. The approach is likely not generalizable as it creates 100s of prompts that are very specific to the two models under consideration.
6. Robustness Checks Are robustness tests (e.g., handling typographical errors, ambiguous queries) documented? Are changes in model performance under these conditions reported?	Clearly Reported Robustness was tested through prompt variation, such as breaking scripts into multiple prompts. Simplifications were required for overly complex RCC calculations, demonstrating some limitations in handling atypical scenarios.
7. Fairness and Bias Monitoring Are outputs evaluated for biases or stereotypes related to gender, age, ethnicity, or other demographics? Are fairness metrics (e.g., demographic parity) used (if applicable), and corrective actions for identified biases documented?	Not Reported The study did not explicitly address fairness or demographic bias. Outputs were focused on technical replication of published models without discussion of bias or fairness in population representation.
8. Deployment Context and Metrics Are deployment setup details (e.g., hardware, software, runnable deployment code) clearly described?	Clearly Reported Deployment used Python and R, with scripts processed on mid-range GPUs. Average generation times were 715 seconds for the NSCLC model and 956 seconds

Are efficiency metrics (e.g., processing time, scalability, resource usage) reported?	for the RCC model. Automation using Python streamlined interactions with GPT-4, improving scalability for larger datasets by reducing manual intervention. Time to create context-specific prompts was not reported.
9. Calibration and Uncertainty	Not Reported
Is the model's uncertainty quantified and explicitly reported (if applicable)? Are thresholds for manual review of outputs (e.g., ambiguous cases flagged in systematic reviews) specified?	Model outputs varied slightly across 15 runs, despite low-temperature settings. Manual quality assurance flagged errors and confirmed minor variability in ICERs. Explicit uncertainty quantification was not performed.
10. Security and Privacy Measures	Clearly Reported
Are security protocols (e.g., encryption, anonymization, access controls) documented? Is compliance with regulations like GDPR or HIPAA reported, if applicable? Is compliance with intellectual property and copyright law documented ?	Dummy data replaced sensitive inputs in prompts due to concerns about LLM data retention. The paper suggests private LLM instances as a future solution to address security and intellectual property concerns.
Overall Score: Assign 3 points for each domain rated as Clearly Reported, 2 points for Ambiguous, and 1 point for Not Reported. Sum the points across all domains to calculate the overall score.	Clearly Reported: 6, Ambiguous: 2, Not Reported: 2 Total Score: 24/30

API = Application Programming Interface; ECE = Expected Calibration Error; ICER = Incremental Cost-Effectiveness Ratio; LLM = Large Language Model; NSCLC = Non-Small Cell Lung Cancer; RCC = Renal Cell Carcinoma

Limitations of the ELEVATE-AI LLMs Framework

The ELEVATE-AI LLMs framework provides a foundational and practical approach for evaluating outputs from LLMs in HEOR. Its application to two published studies illustrates its utility in practice. While the framework is designed to be simple and broadly applicable, it nonetheless has several limitations that warrant consideration for refinement and future applications. First, the generalizability of the framework across diverse HEOR tasks—such as systematic literature reviews, HEM, and RWE generation—requires further empirical testing. While ELEVATE-AI LLMs was designed to be broadly applicable, its effectiveness has only been applied to two narrowly defined use cases. As the framework is applied to other HEOR tasks, its strengths and limitations in different contexts will become clearer. Second, applying the framework's domains is not always straightforward. For example, differentiating between Accuracy and Comprehensiveness can be challenging, as the concepts overlap in some cases. In abstract screening, distinguishing between including relevant abstracts (accuracy) and including all relevant abstracts (comprehensiveness) can be nuanced. Similarly, reproducibility is a critical domain but remains difficult to achieve due to variability in computational environments, data access, and prompt design. Even with open-source models, it is not clear that outputs could be exactly reproduced by independent researchers. Closed-source models, like GPT-4, add further complexity, as their continuous updates and fine-tuning may potentially affect outputs. Future iterations of the framework should consider methods to mitigate these challenges, including clearer reporting standards and guidance for framework users on cases where certain domains may be less applicable.

Third, future work will involve reviewing and adapting metrics from computer science and ML to the specific needs of research tasks and sub-tasks common in HEOR. Metrics such as ECE, robustness measures, and accuracy metrics require further adaptation and validation to ensure their relevance to HEOR tasks, such as parameter estimation or health state identification. Similarly, evaluating fairness and bias presents challenges, as HEOR datasets may underrepresent certain populations, potentially perpetuating health disparities. To address the variability in the maturity of these metrics, we propose assigning a "level of maturity" for each domain to indicate how advanced or emerging the measurement of that domain might be. Future efforts should prioritize the development of fairness metrics tailored to HEOR applications, provide practical guidance for interpreting and reporting these measures, and refine emerging metrics as the field evolves. Results of HEOR studies are used to inform a variety of decisions that influence patient access to healthcare. Therefore, HEOR professionals should continue to apply their good practices (and good judgement) to the ethical deployment of LLMs. Finally, the quality of LLM-generated outputs depends on both user expertise (e.g., prompt design and domain knowledge) and the intrinsic performance of the model. Differentiating between these contributions is difficult, and methods to evaluate them are still evolving. Nevertheless, understanding this interplay is essential for refining and optimizing LLM use in HEOR.

Despite these limitations, the ELEVATE-AI LLMs framework offers a robust starting point for authors and reviewers to report and evaluate LLMs use in HEOR studies. As evidence accumulates and the framework is refined, it has the potential to play a pivotal role in fostering the responsible and transparent integration of LLMs into HEOR research.

20

Conclusion

The rapid expansion of LLMs within HEOR necessitates the adoption of rigorous, standardized evaluation frameworks. LLMs hold transformative potential for advancing SLRs, HEM, RWE generation, and many other core HEOR activities. To fully harness these capabilities, it is essential to ensure the accuracy, transparency, and reliability of LLM-generated outputs through structured and consistent evaluation criteria, as proposed in the ELEVATE-AI LLMs framework. The ELEVATE-AI LLMs framework offers HEOR professionals a practical and comprehensive guide for assessing both the foundational characteristics of LLMs and the quality of their outputs. Despite its utility, applying the ELEVATE-AI LLMs framework presents challenges. The use cases in this paper underscore complexities in areas such as reproducibility, fairness and bias monitoring, robustness testing, and calibration. These challenges highlight the need for ongoing refinement and adaptation of the framework as the technology and its applications evolve and the need to further develop metrics that are applicable to HEOR tasks. As generative AI and LLM technology advance, evaluation criteria must evolve in tandem. While the ELEVATE-AI LLMs framework offers a strong foundation, it must remain dynamic and responsive to emerging best practices and unforeseen challenges. By committing to rigorous, standardized evaluations, HEOR professionals can ensure the responsible integration of LLMs into research, safeguarding scientific integrity while unlocking the full potential of generative AI.

Glossary (based on Fleurence, 2024a)¹

• Artificial Intelligence (AI): A broad field of computer science that aims to create intelligent machines capable of performing tasks typically requiring human intelligence.

• Area Under the Curve (AUC): A performance metric for classification models that measures the ability to distinguish between classes. It represents the area under the Receiver Operating Characteristic (ROC) curve, summarizing the trade-off between sensitivity (recall) and specificity. A higher AUC indicates better model performance.

• **Deep Learning:** A subset of machine learning algorithms that uses multilayered neural networks, called deep neural networks. These algorithms are the core behind the majority of advanced AI models.

• Expected Calibration Error (ECE): A metric that evaluates how well a model's predicted probabilities align with the actual likelihood of an event occurring. Low ECE indicates better-calibrated predictions, which is critical for applications requiring reliable confidence scores.

• **F1 Score:** A metric that balances precision and recall, calculated as the harmonic mean of these two measures. It is particularly useful for evaluating models in scenarios where false positives and false negatives have unequal consequences.

• Foundation Model: Large-scale pretrained models that serve a variety of purposes. These models are trained on broad data at scale and can adapt to a wide range of tasks and domains with further fine-tuning.

• Generative AI: AI systems capable of generating text, images, or other content based on input data, often creating new and original outputs.

• Generative Pre-trained Transformer (GPT): A specific series of LLMs created by OpenAI based on the Transformer architecture, which is particularly well-suited for generating human-like text.

• Large Language Model (LLM): A specific type of foundation model trained on massive text data that can recognize, summarize, translate, predict, and generate text and other content based on knowledge gained from massive datasets.

• Machine Learning (ML): A field of study within AI that focuses on developing algorithms that can learn from data without being explicitly programmed.

• **Multimodal AI:** An AI model that simultaneously integrates diverse data formats provided as training and prompt inputs, including images, text, bio-signals, -omics data, and more.

• **Precision:** A metric that evaluates the proportion of true positive predictions among all positive predictions made by a model. High precision indicates fewer false positives, which is essential in tasks where accuracy of positive classifications is critical.

• **Prompt:** The input given to an AI system, consisting of text or parameters that guide the AI to generate text, images, or other outputs in response.

• **Prompt Engineering:** Creating and adapting prompts (input) to instruct AI models to generate specific outputs.

• **Recall:** A metric that evaluates the proportion of true positive predictions among all actual positive cases. High recall indicates fewer false negatives, which is crucial for tasks where capturing all relevant instances is a priority.

• **Token:** A unit of text processed by an AI model, which can be a word, subword, or character. AI models convert input text into tokens to generate or interpret language. The number of tokens impacts model performance, cost, and the ability to process longer texts efficiently.

Box 1: Prompt for Applying the ELEVATE-AI LLMs Checklist to a Study:

"Using the ELEVATE-AI LLMs checklist, evaluate the study titled *(Insert Study Title)* for its use of large language models (LLMs) in Health Economics and Outcomes Research (HEOR). For each domain, assess whether the study meets the criteria described in the checklist, assigning a score of 3 (Clearly Reported), 2 (Ambiguous), or 1 (Not Reported). Calculate the total score and provide a summary of the study's reporting quality, identifying strengths and areas for improvement in transparency and methodological rigor."

Supplemental Material: Applications of the ELEVATE-AI LLMS Framework to HEOR Activities

To demonstrate its utility, the ELEVATE-AI LLMS framework was applied to two key tasks in HEOR: SLR abstract screening and the development of a cost-effectiveness model. These examples illustrate the framework's flexibility and its ability to guide evaluations across diverse research activities within HEOR. While these tasks highlight specific applications, the ELEVATE-AI LLMS framework is designed to be broadly applicable to a wide range of HEOR tasks involving LLM assistance, extending beyond the examples provided.

ELEVATE-AI LLMS Framework Application to SLR Abstract Screening Task augmented with LLMs:

The Supplemental Table demonstrates the generic application of the ELEVATE-AI LLMS framework to systematic literature review (SLR) tasks, specifically focusing on abstract screening. It provides examples of reporting requirements for each evaluation domain. While this example emphasizes abstract screening for simplicity, the framework could be equally applicable to other SLR tasks, such as full-text screening and data extraction and such applications could be the focus of future work of the ISPOR Working Group on Generative AI

The ELEVATE-AI LLMS framework might be applied as follows. For Model Characteristics, researchers should detail the model's name, version (and version history), developer(s), training data, and any task-specific fine-tuning performed. For abstract screening, metrics such as precision, recall, and F1 score may be reported under Accuracy Assessment, with comparisons to human benchmarks or gold-standard datasets to validate performance. For many specific tasks in HEOR research, identifying appropriate metrics, adapting those commonly used in the general machine learning field, remains an ongoing area of research. The Comprehensiveness Assessment ensures that the LLM captures all relevant abstracts by comparing outputs to expert-validated gold standards, while Factuality Verification focuses on confirming the reliability of the model's inclusion/exclusion decisions through source validation. Additional domains, such as Reproducibility Protocols and Generalizability and Robustness Checks, emphasize the importance of documenting workflows, sharing code, and assessing the model's resilience to input variations. Fairness and Bias Monitoring, requires the evaluation of demographic

representation in screening outputs, while Security and Privacy Measures highlight data protection and regulatory compliance, including copyright protection. Finally, practical aspects such as Deployment Context and Efficiency Metrics and Calibration and Uncertainty provide insights into resource efficiency and confidence management during screening, ensuring the framework's comprehensive applicability to SLR tasks. An overall evaluation score can be calculated as described in the table.

ELEVATE-AI LLMS Framework application to health economic model generation augmented with LLMs:

The Supplemental Table illustrates how the ELEVATE-AI LLMS framework might be applied to assist with the conceptual model development for cost-effectiveness models, including generating the structure and identifying health states, by outlining specific reporting requirements for each domain. The ELEVATE-AI LLMS framework might be applied as follows. For Model Characteristics, researchers should document details about the model, such as its name, version, developer, and training data sources, and note whether fine-tuning was conducted using published cost-effectiveness models. Accuracy Assessment involves validating the LLM's proposed health state suggestions by comparing them to gold-standard models and incorporating expert validation by health economists as a benchmark. Because accuracy metrics like precision and recall may not be applicable to this use case, future work is needed to identify metrics best suited for such applications. The Comprehensiveness Assessment ensures that the LLM's outputs address all critical health states and transitions by comparing them to established benchmarks and conducting expert reviews to identify any gaps. Factuality Verification focuses on confirming the accuracy of health state definitions and transition probabilities by crossreferencing outputs with authoritative sources such as NICE guidelines or validated costeffectiveness models, with discrepancies documented and addressed. To support transparency, the Reproducibility Protocols domain emphasizes documenting prompts, parameters (e.g., temperature settings), and workflows used to generate the model structure, enabling independent validation. The generalizability of the model's use for other research questions should also be discussed. Robustness Checks assess whether the LLM produces consistent recommendations across different input variations, such as changing the specificity of prompts (e.g., general health state suggestions versus detailed Markov model requests). Fairness and Bias

Monitoringevaluates whether health state recommendations are equitable across populations and free from demographic biases. Practical feasibility is examined under Deployment Context and Metrics, requiring descriptions of the computational setup (e.g., GPU hardware, software frameworks) and metrics like processing time or scalability for large datasets. The framework also incorporates Calibration and Uncertainty measures to assess confidence in the LLM's recommendations, identifying areas where uncertainty is flagged (e.g., ambiguous or insufficiently supported health state definitions) and providing thresholds for manual review. Metrics like ECE may not be applicable to this use case. Finally, Security and Privacy Measures ensure compliance with regulatory standards, such as GDPR and HIPAA if applicable, for example by requiring data anonymization and secure handling of sensitive or proprietary datasets. Copyright protection should also be discussed. Together, these domains provide a structured approach to evaluating the application of LLMs in cost-effectiveness modeling. An overall score can be calculated as described in the table.

Supplemental Table: Description of the features of ELEVATE-AI LLMS Framework as relevant to (1) Systematic Literature Review Abstract Screening and (2) Conceptual Model Development for Cost-Effectiveness Analysis

Domain Name	Examples of what to report when using LLMs to assist with Abstract Screening in a SLR	Examples of what to report when using LLMs to assist with model structure generation and health state identification
Model Characteristics	 -Report the model details, including its name (e.g., GPT-4), version, developer (e.g., OpenAI), release date (e.g., March 2023), and architecture (e.g., transformer-based) and license (e.g. commercial model). -Describe the training data sources relevant to SLR screening tasks, such as PubMed or Cochrane abstracts. -Indicate if additional fine-tuning was conducted to optimize the model for inclusion/exclusion criteria using RLHF or other techniques. 	-Report the LLM's name (e.g., GPT-4), version, developer (e.g., OpenAI), release date (e.g., March 2023), license (e.g. commercial or open-source) and architecture (e.g., transformer-based). -Describe the primary training data sources. Note if the LLM was fine- tuned using high-quality, existing published models (e.g., systematic reviews of cost-effectiveness models).
Accuracy Assessment	 -If appropriate for the task at hand, report task-specific metrics (e.g., precision, recall, F1 score, AUC) to evaluate the accuracy of outputs. -Compare these metrics against human benchmarks or gold-standard datasets (e.g., Cochrane screening datasets). 	-Evaluate the accuracy of the LLM's proposed model structure by comparing its health state suggestions against published gold-standard models. -Evaluate the accuracy of the LLM's proposed input parameters by comparing its suggested parameter values against published gold-standard models.

		-Include human validation by expert health economists as a key benchmark.
Comprehensiveness Assessment	 Evaluate whether the foundation model captures all potentially relevant abstracts during screening. Validate comprehensiveness by comparing the model's outputs to a gold-standard list of abstracts identified by domain experts or exhaustive manual review. Use benchmarks such as recall metrics to measure the percentage of relevant abstracts identified, supplemented by expert analysis to identify any critical gaps in inclusion. 	-Assess the comprehensiveness of the foundation model's suggested structure and parameters for the cost- effectiveness model by comparing them to benchmarks from established published models. -Incorporate expert review to identify any missing health states or input parameters critical to the research task.
Factuality Verification	 -Describe methods for verifying factual accuracy, such as cross-checking the LLM's outputs against primary sources (e.g., PubMed). -Document any discrepancies identified (e.g., hallucinated citations) and corrective actions taken (e.g., excluding non-verifiable results). 	 -Verify the factuality of the LLM's outputs by cross-referencing health state definitions and transition probabilities with authoritative sources, such as NICE guidelines or validated cost-effectiveness models. -Document discrepancies and describe how they were resolved, if applicable.
Reproducibility Protocols and Generalizability	 -Detail reproducibility protocols, including sharing training and preprocessing code (e.g., Python scripts for data preparation), hyperparameters (e.g., learning rate = 1e-5, batch size = 32), and validation datasets (e.g., Cochrane dataset split into 80/10/10 for training/validation/testing). - Discuss generalizability of approach to other research questions. 	 Provide a detailed record of the prompts and parameters (e.g., temperature settings) used to generate the cost-effectiveness model structure, including query phrasing and temperature settings. Share any reproducible workflows or code that enable independent verification of the outputs. Discuss generalizability of approach to other research questions.
Robustness Checks	-Describe robustness checks, such as introducing typographical errors (e.g., misspelled keywords) or ambiguous phrasing in abstracts, and report performance metrics under these conditions (e.g., F1 score drop of 5%). -Include qualitative assessments of handling conflicting or ambiguous inputs.	-Test the robustness of the LLM's recommendations by altering input prompts, such as varying the specificity of the request (e.g., 'suggest health states for a Hepatitis C model' vs. 'develop a five-state Markov model for Hepatitis C'). -Assess whether the suggested health states remain consistent across different input variations.
Fairness and Bias Monitoring	 -Assess demographic representation in screening outputs (e.g., stratify results by study population demographics). -Use fairness metrics (e.g., demographic parity) to evaluate bias. Document corrective measures for identified imbalances (e.g., reweighting or prompt adjustments). - In the absence of available metrics, provide narrative discussion of issues of fairness and bias. 	-Evaluate the LLM's outputs to ensure that the recommended health states and transition probabilities are equitable across populations. For example, check whether the model suggests gender- or age-specific health states that reflect documented epidemiological data and avoid perpetuating biases. - In the absence of available metrics, provide narrative discussion of issues of fairness and bias.

F	Τ	Г
Deployment Context and Metrics	-Report the deployment setup, including hardware (e.g., NVIDIA A100 GPUs), software (e.g., Python with TensorFlow), and platforms (e.g., AWS cloud infrastructure). -Include efficiency metrics such as processing speed (e.g., 1,000 abstracts screened per minute) and computational costs (e.g., GPU hours used).	-Describe the deployment setup, including hardware (e.g., NVIDIA A100 GPUs) and software frameworks (e.g., TensorFlow or PyTorch). -Report efficiency metrics such as time required to generate a complete model structure (e.g., 2 minutes for a 5-state Markov model) and scalability when processing larger data inputs (e.g., recommendations for 10 different disease models).
Calibration and Uncertainty	-Describe methods to assess confidence in inclusion/exclusion decisions during abstract screening -Specify thresholds for flagging uncertain outputs for manual review (e.g., abstracts with confidence below 70%).	 -Report confidence levels for the LLM's recommendations on health state definitions. -Highlight areas where uncertainty is flagged, such as cases with insufficient training data or ambiguous health state definitions,
Security and Privacy Measures	 -Document security measures for data handling, including compliance with privacy standards (e.g., GDPR). - Report safeguards for model outputs, such as encryption and access controls, and describe steps taken to protect copyrighted or proprietary content. 	-Describe privacy measures applied when using sensitive data to fine-tune the LLM, ensuring compliance with ethical and regulatory standards (e.g., de-identifying patient-level data). -If the LLM incorporates proprietary data, detail steps taken to protect intellectual property and ensure secure data handling.
Overall Score	Assign 3 points for each domain rated as Clearly Reported, 2 points for Ambiguous, and 1 point for Not Reported. Sum the points across all domains to calculate the overall score.	Assign 3 points for each domain rated as Clearly Reported, 2 points for Ambiguous, and 1 point for Not Reported. Sum the points across all domains to calculate the overall score.
