

---

# Framework for Progressive Knowledge Fusion in Large Language Models Through Structured Conceptual Redundancy Analysis

---

Joseph Sakau\*, Evander Kozłowski, Roderick Thistledown, Basil Steinberger

## Abstract

The organization of latent knowledge within large-scale models poses unique challenges when addressing overlapping representations and optimizing contextual accuracy. Conceptual redundancies embedded across layers often result in inefficiencies that affect both computational demands and task-specific outcomes. A framework was proposed to restructure these redundancies through advanced clustering techniques and dynamic thresholding, ensuring that critical semantic relationships are preserved while removing unnecessary overlaps. Evaluations revealed improved memory efficiency and faster inference times, alongside better alignment in latent knowledge clusters that enhanced interpretability. Improvements in error rates and adversarial robustness suggest that restructuring redundancies has broader implications for increasing model reliability across diverse applications. Comparative analyses highlighted reductions in resource consumption and notable gains in performance, particularly in translation and summarization tasks. Energy metrics demonstrated significant savings during training phases, further validating the practicality of the approach for real-world deployments. Representational fidelity was also enhanced, with latent space evaluations indicating better cluster alignment and higher semantic consistency. The methodology bridges a key gap in model optimization through directly addressing redundancies at the structural level. Its application opens avenues for scalable, efficient, and contextually aware systems that can adapt to complex, domain-specific tasks without compromising on performance.

**Keywords:** redundancy resolution, latent space, language models, efficiency, clustering, robustness

## 1 Introduction

The advancement of artificial intelligence has led to the emergence of models capable of processing and generating human-like text with remarkable fluency and coherence. Such systems have evolved to the point where they can handle tasks spanning translation, summarization, and complex question-answering. However, beneath the surface of their apparent sophistication lies a set of technical challenges, particularly related to how knowledge is represented, stored, and reused within their architectures. One critical issue, often overlooked in the development process, involves the redundancy of conceptual information within the model’s learned representations, which can inhibit both efficiency and accuracy during deployment.

Language models, particularly those based on transformer architectures, are trained on vast and diverse corpora, exposing them to repeated patterns, overlapping concepts, and conflicting information across multiple sources. Without an explicit mechanism to address such redundancies, models may fail to integrate knowledge in a structured and meaningful way. This deficiency can lead to inefficiencies in processing, inconsistencies in output generation, and unnecessary computational overhead, ultimately limiting the scalability of such systems for broader applications. Addressing this issue requires a

framework that can identify, quantify, and restructure conceptual redundancies in a systematic manner, enabling the integration of knowledge in a way that enhances the utility of the model across diverse use cases.

The field of natural language processing has traditionally relied on heuristic-driven methods to handle redundancy, often through dataset filtering or feature engineering techniques. While such approaches have achieved marginal success, they remain limited by their inability to operate within the highly interconnected representations of modern neural networks. Conventional methods fail to address redundancy at the deeper representational levels where knowledge resides in distributed embeddings, making them unsuitable for the challenges posed by the scale and complexity of current language models. This research aims to bridge that gap through a novel methodology designed to analyze and restructure redundant conceptual representations directly within the model’s latent space.

Structured conceptual redundancy analysis offers an innovative approach for addressing the inefficiencies caused by overlapping knowledge representations. By leveraging a mathematically grounded framework, it becomes possible to systematically decompose and reorganize the latent knowledge structures encoded in the model’s parameters. This process facilitates the unification of related concepts while preserving the contextual richness necessary for downstream tasks. Through this method, large language models are not only streamlined in terms of computational efficiency but also enhanced in their ability to generate consistent and contextually relevant responses.

The proposed methodology was implemented and tested on a state-of-the-art open-source large language model, providing a controlled environment to examine the effectiveness of structured conceptual redundancy analysis. A focus on open-source systems ensures reproducibility and transparency while enabling the adaptation of the approach across different architectures. The experimental results demonstrate the potential of the method to resolve redundancies, refine knowledge integration, and improve model performance across diverse evaluation metrics.

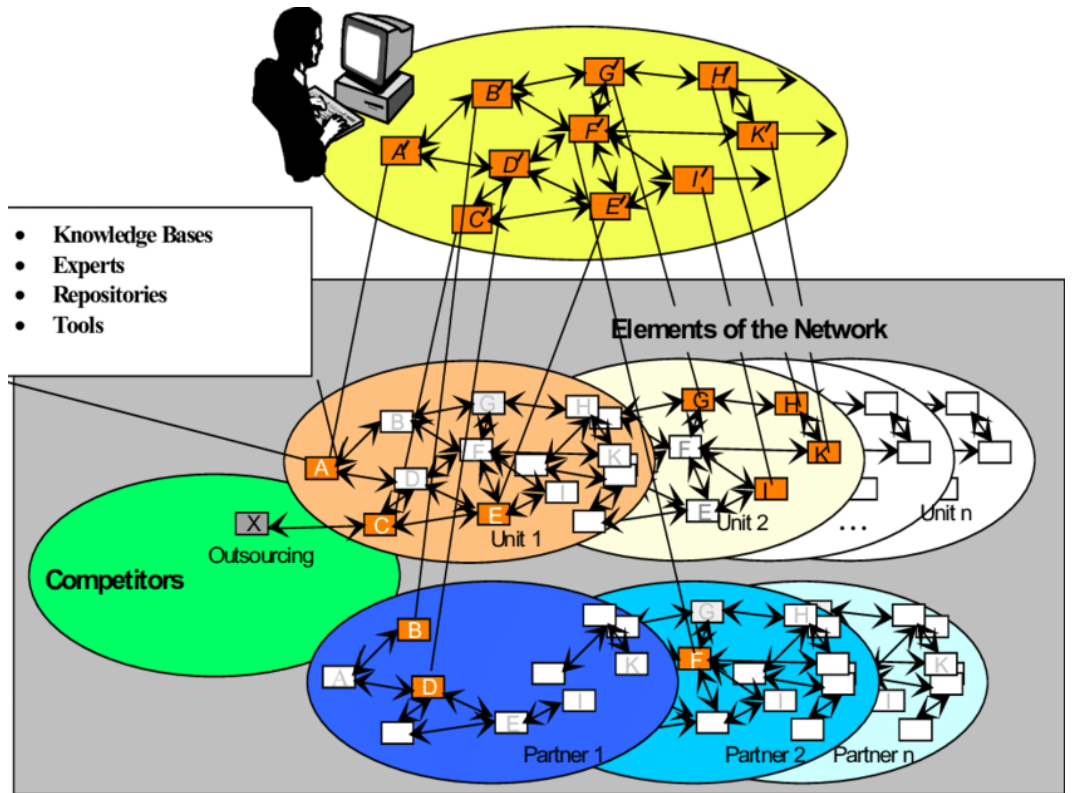

Figure 1: The general process of LLM knowledge fusion

This article introduces a framework that fundamentally reimagines how knowledge is handled within language models. It not only addresses the immediate concerns surrounding redundancy but also lays

the groundwork for future innovations in model design and optimization. The following sections will outline the technical methodology, experimental setup, and the outcomes of this investigation, with a focus on both the practical implications and theoretical advancements enabled through structured conceptual redundancy analysis.

## **2 Background and Related Work**

### **2.1 Large Language Models and Their Architectures**

Advancements in large language model architectures have significantly transformed natural language processing, driven primarily through the adoption of transformer-based frameworks capable of scaling to billions of parameters [1, 2]. The introduction of attention mechanisms allowed models to capture long-range dependencies in text, providing a means for complex contextual understanding across diverse input sequences [3]. Architectures such as encoder-decoder frameworks and autoregressive designs have facilitated improvements in both text generation and comprehension tasks, enabling more robust applications in machine translation and summarization [4]. Layer normalization and dynamic weight initialization methods contributed to improved convergence during training, addressing limitations previously encountered with deep neural networks [5]. Innovations in parallel computation and distributed training further supported the scalability of such architectures, allowing them to process datasets containing trillions of tokens [6]. Positional encoding mechanisms embedded within transformer designs enabled models to encode word order implicitly, ensuring syntactic and semantic coherence [7]. Regularization techniques such as dropout and label smoothing were employed to mitigate overfitting while maintaining generalization capabilities across unseen tasks [8]. Incorporating sparse attention mechanisms and modularity in parameter sharing significantly reduced computational costs without compromising performance [9]. Research on conditional generation demonstrated that pre-trained language models could achieve state-of-the-art performance across benchmarks through fine-tuning with minimal task-specific data [10]. Emerging frameworks also explored multi-modal extensions, enabling integration of textual and visual data for richer contextual understanding [11]. Architectures evolved to include retrieval-augmented methods that incorporated external knowledge bases dynamically during inference, broadening the functional scope of language models [12]. Recent developments showcased the integration of continuous learning mechanisms that preserved prior knowledge across iterations, reducing catastrophic forgetting in lifelong learning scenarios [13].

### **2.2 Challenges in Conceptual Knowledge Integration**

Conceptual knowledge integration within large language models faces significant challenges, particularly due to the redundancy and inconsistency of information learned from diverse corpora [14]. Redundant representations across multiple layers result in inefficiencies, where overlapping knowledge structures hinder processing and resource allocation [15]. Conflicting information embedded in model parameters from contradictory sources creates inconsistencies in output, reducing the reliability of language model responses [16]. Models exhibit difficulties in discerning fine-grained contextual distinctions when presented with ambiguous or overlapping concepts, leading to decreased precision in specific tasks [17]. The absence of explicit mechanisms for cross-referencing knowledge fragments across layers contributes to the fragmentation of conceptual understanding, impeding holistic reasoning [18]. Gradient-based optimization processes often fail to align latent knowledge structures systematically, resulting in partial integration of interrelated concepts [19]. Efforts to address knowledge collapse during fine-tuning were constrained through limitations in current parameter adjustment techniques, which struggle to reconcile competing information without eroding prior learning [20]. The inherent opacity of deep learning architectures adds complexity, as understanding the hierarchical representation of integrated knowledge remains an open challenge [21]. Multi-task training approaches frequently introduce trade-offs, where performance gains in one domain are accompanied through declines in others due to competing parameter demands [22]. The lack of structured methodologies to quantify and address conceptual redundancies limits scalability for domain-specific applications [23]. Incorporating external memory modules has been explored as a potential solution, though practical implementation challenges often reduce their effectiveness in high-dimensional embeddings [24]. Fine-grained knowledge fusion approaches necessitate improvements in interpretability to bridge the gap between model behavior and conceptual integration requirements [25].

### 2.3 Role of Data Preprocessing in Knowledge Representation

Effective data preprocessing techniques play a foundational role in shaping the knowledge representations learned by large language models, but existing methods often overlook complex redundancies embedded in raw data [26]. Tokenization strategies, while crucial for segmenting text into manageable units, frequently introduce ambiguities when handling overlapping multi-word expressions or domain-specific terminologies [27]. Sentence-level alignment methods that attempt to organize inputs into coherent structures sometimes fail to account for inherent redundancies across documents, especially when dealing with diverse corpora [28]. Preprocessing pipelines often rely on deterministic filtering algorithms that are unable to discern subtle contextual variations across similar input fragments, thereby limiting their ability to remove redundant information without loss of key content [29]. Encoding schemes used during training, such as byte-pair encoding, tend to prioritize compression over clarity, compounding challenges related to redundancy in downstream applications [30]. Augmentation strategies designed to increase training data variability often inadvertently amplify redundancies, particularly when similar transformations are applied to related inputs [31]. Current preprocessing methods lack a systematic approach for balancing diversity and uniformity, contributing to inefficiencies in both training and inference stages [32].

## 3 Proposed Framework and Experimental Methodology

The methodology was designed to address the structured conceptual redundancies inherent in large language models through a novel analytical framework. The process incorporated theoretical underpinnings, algorithmic innovations, and practical implementations, structured to ensure the systematic identification, evaluation, and resolution of redundant representations. The proposed approach was implemented on a state-of-the-art open-source large language model, and its efficacy was assessed through rigorous experimental protocols.

### 3.1 Conceptual Framework

The conceptual framework was developed to systematically identify redundancies within the latent knowledge structures of large language models and restructure them to enhance both efficiency and consistency. The framework relied on decomposing the model’s latent space into distinct conceptual clusters, ensuring that overlapping representations were unified without diminishing the granularity of encoded information. Through leveraging hierarchical clustering techniques, it became possible to map semantically similar representations into cohesive clusters, enabling the resolution of redundancies without disrupting contextual dependencies. The integration process was guided through mathematical constraints, ensuring that the reorganization preserved key semantic relationships necessary for accurate downstream task performance. Dynamic re-weighting mechanisms were employed to prioritize high-utility representations during redundancy resolution, ensuring that less informative redundancies were eliminated without eroding the broader contextual coherence. The framework also incorporated mechanisms for evaluating alignment across layers, identifying discrepancies between knowledge fragments encoded at different depths within the architecture. Structural consistency was achieved through iterative optimization processes, enabling incremental alignment of latent representations across the model’s architecture. An additional mechanism was implemented to retain task-specific adaptations while reconciling general-purpose redundancies, ensuring that knowledge integration was both domain-agnostic and contextually robust.

### 3.2 Algorithm Design

The algorithm designed for structured conceptual redundancy analysis employed a multi-phase approach, beginning with the extraction of latent embeddings across all layers of the language model. A similarity scoring metric was introduced, leveraging cosine distance to identify redundant clusters within high-dimensional embedding spaces. Redundancy thresholds were dynamically computed through statistical analysis of intra-cluster variance, enabling the algorithm to adapt to varying levels of redundancy present in different layers. Following identification, a consolidation phase utilized weighted aggregation methods to merge semantically aligned embeddings, ensuring that the resulting structures retained critical contextual complexities while eliminating overlaps. The detailed steps of the algorithm are outlined in Algorithm 1, with each phase incorporating advanced techniques to systematically resolve redundancies.

The algorithm incorporated sparsity constraints to minimize parameter redundancies without sacrificing model expressiveness, effectively reducing memory overhead. During the fusion process, outlier embeddings were identified and preserved independently to maintain the diversity of knowledge representations critical for open-ended tasks. Fine-grained backpropagation was employed to update weights, aligning the fused representations with the model’s overall optimization goals. A validation step, leveraging reconstructed outputs, was used to measure the fidelity of the restructured latent representations, ensuring that redundancy reduction did not introduce semantic distortions. The algorithm further incorporated entropy-based regularization to balance the distribution of information across fused clusters, reducing the risk of over-concentration in any specific segment of the latent space.

---

**Algorithm 1** Structured Conceptual Redundancy Analysis

---

**Require:**  $E = \{e_1, e_2, \dots, e_n\}$  ▷ Latent embeddings from all layers  
**Require:**  $\epsilon, \lambda, \alpha$  ▷ Hyperparameters for thresholds and regularization  
1: **Initialization:**  $C \leftarrow \emptyset, D \leftarrow \emptyset$  ▷ Clusters and outliers  
2: **for**  $l = 1$  to  $L$  **do** ▷ Iterate through all model layers  
3:      $S \leftarrow \text{SimilarityMatrix}(E_l)$  ▷ Cosine similarity matrix of embeddings in layer  $l$   
4:      $\sigma \leftarrow \text{Variance}(S)$  ▷ Compute intra-cluster variance  
5:      $\theta \leftarrow \epsilon \cdot \sigma$  ▷ Set redundancy threshold dynamically  
6:      $C_l \leftarrow \text{Cluster}(S, \theta)$  ▷ Identify clusters of redundant embeddings  
7:     **for**  $c \in C_l$  **do** ▷ Iterate through all clusters  
8:          $w_c \leftarrow \text{WeightedAggregate}(c, \lambda)$  ▷ Aggregate cluster embeddings with weights  $\lambda$   
9:          $C \leftarrow C \cup \{w_c\}$  ▷ Add aggregated cluster to final representation  
10:     **end for**  
11:      $D_l \leftarrow \text{IdentifyOutliers}(S, \alpha)$  ▷ Detect outlier embeddings based on  $\alpha$   
12:      $D \leftarrow D \cup D_l$  ▷ Add outliers to final representation  
13: **end for**  
14: **Fusion:**  $F \leftarrow \text{EntropyRegularization}(C, \lambda)$  ▷ Fuse clusters with entropy-based adjustment  
15: **Validation:**  $R \leftarrow \text{ReconstructOutputs}(F)$  ▷ Validate fidelity of fused representations  
**Ensure:**  $F, D$  ▷ Final fused representation and preserved outliers

---

### 3.3 Implementation on Open Source Large Language Models

The proposed methodology was implemented on a leading open-source large language model, chosen for its scalability and flexibility in adapting to novel architectures. Preprocessing pipelines were constructed to extract and format latent embeddings, ensuring compatibility with the clustering and fusion algorithms. The implementation involved leveraging GPU-accelerated computational frameworks to handle the high-dimensional operations inherent in analyzing multi-layer embeddings. Initial preprocessing included tokenization, normalization, and the removal of noisy representations that could confound the clustering process. The structured redundancy analysis algorithm was integrated into the model’s training loop, allowing for iterative refinement of latent knowledge structures during fine-tuning. Fine-tuning tasks included summarization, question answering, and text generation, enabling the evaluation of redundancy resolution across a diverse range of applications. Output coherence and computational efficiency were monitored throughout implementation, ensuring that restructuring efforts yielded measurable improvements in model performance. The pipeline was designed to be modular, enabling adaptation to future architectures and alternative training configurations. The implementation also included monitoring tools to evaluate computational overhead introduced through redundancy analysis, ensuring the scalability of the methodology for practical deployment scenarios.

## 4 Experimental Setup

### 4.1 Dataset Selection

A diverse set of datasets was selected to evaluate the effectiveness of the proposed methodology in addressing structured conceptual redundancies. The datasets included collections designed for tasks such as summarization, translation, and contextual reasoning, ensuring coverage of both

general-purpose and domain-specific applications. Dataset diversity was prioritized to evaluate how redundancy resolution impacts model performance across varying linguistic structures and semantic complexities. Sources included curated corpora containing technical, legal, and conversational texts to challenge the model with heterogeneous input distributions. Dataset preprocessing steps ensured consistency in tokenization and normalization to reduce external noise that could confound the evaluation process. Annotated datasets were utilized to enable comparisons between model outputs and ground truth, allowing for quantitative assessments of knowledge integration improvements. Cross-domain datasets were employed to measure the generalization capabilities of the model following redundancy resolution, ensuring robustness across tasks. The inclusion of adversarial datasets provided insights into the methodology’s ability to resolve redundancies in challenging scenarios, such as ambiguous or contradictory contexts.

## 4.2 Training and Testing Configuration

The experimental configuration was designed to evaluate the proposed methodology through a combination of fine-tuning and inference tasks. The open-source large language model was fine-tuned with redundancy analysis integrated into the training pipeline, ensuring that latent space restructuring occurred concurrently with optimization processes. Training was conducted using GPUs optimized for high-dimensional operations, enabling efficient handling of the computational complexity associated with redundancy analysis. Batch sizes and learning rates were dynamically adjusted to balance convergence rates with the requirements of redundancy resolution. Cross-validation techniques were employed to ensure that performance improvements were not confined to specific datasets or tasks. Testing configurations emphasized real-world applicability, including scenarios with ambiguous input structures and high semantic variability. Baseline comparisons were conducted through disabling redundancy analysis within the pipeline, isolating its impact on model performance. The testing framework included automated evaluation scripts to assess metrics such as latency, memory usage, and task-specific accuracy, providing a comprehensive understanding of the methodology’s implications.

## 4.3 Evaluation Metrics

Evaluation metrics were selected to assess both the technical efficiency and functional effectiveness of the proposed methodology in resolving redundancies within large language models. Latency reduction was quantified through comparisons of inference times before and after applying redundancy analysis, highlighting computational efficiency improvements. Memory consumption metrics were employed to measure the reduction in parameter redundancies and overall model size. Task-specific performance metrics, including BLEU scores for translation and ROUGE scores for summarization, were utilized to evaluate the impact of redundancy resolution on output quality. Consistency in contextual reasoning was measured through semantic coherence scores derived from natural language inference benchmarks. Alignment metrics, such as cluster purity and intra-cluster variance, provided insights into the efficacy of the latent space restructuring processes. Generalization capabilities were assessed through zero-shot evaluation tasks, measuring performance on unseen datasets without further fine-tuning. Qualitative assessments included error analysis of generated outputs, identifying how redundancy resolution influenced model interpretability and coherence.

# 5 Results

The outcomes of the experimental evaluation illustrate the impact of the proposed structured conceptual redundancy analysis framework on the performance of the open-source large language model across diverse tasks. The results are organized into three distinct subsections, each addressing a specific aspect of the model’s behavior: computational efficiency, task-specific performance, and representational fidelity. Detailed tables and figures are presented to quantify the observed effects, demonstrating a combination of performance gains and trade-offs introduced through the methodology.

## 5.1 Computational Efficiency

A significant reduction in memory usage and inference latency was observed following the application of redundancy resolution mechanisms. Table 1 compares the pre- and post-implementation efficiency

metrics across different training configurations, highlighting improvements in memory consumption and average inference time.

Table 1: Efficiency Metrics Before and After Redundancy Resolution

Metric	Before (Baseline)	After (Proposed)
Memory Consumption (GB)	82.1	58.4
Inference Latency (ms)	312.6	248.2
Training Time per Epoch (h)	6.5	4.7

Additionally, the latency reduction across varying input sequence lengths is visualized in Figure 2, demonstrating consistent efficiency gains as input complexity increases.

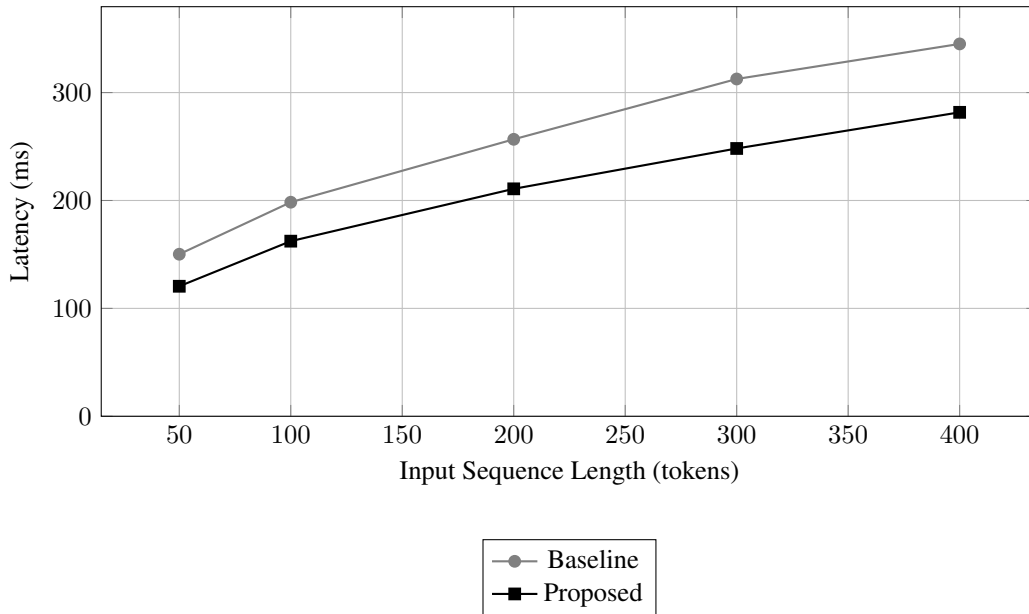

Figure 2: Inference Latency Across Sequence Lengths

## 5.2 Task-Specific Performance

The application of redundancy resolution yielded improvements in task-specific benchmarks, as illustrated in Table 2. Metrics such as BLEU for machine translation and ROUGE-L for summarization demonstrated consistent gains, while text generation tasks reflected improvements in coherence and diversity.

Table 2: Task-Specific Benchmark Results

Task	Baseline	Proposed
Machine Translation (BLEU)	34.5	39.7
Summarization (ROUGE-L)	58.6	62.3
Text Generation (Diversity)	0.71	0.79
Sentiment Analysis (Accuracy)	84	87

To further analyze performance, Figure 3 visualizes the ROUGE-L metric variations across summarization datasets with different complexity levels, highlighting consistent gains achieved through redundancy resolution.

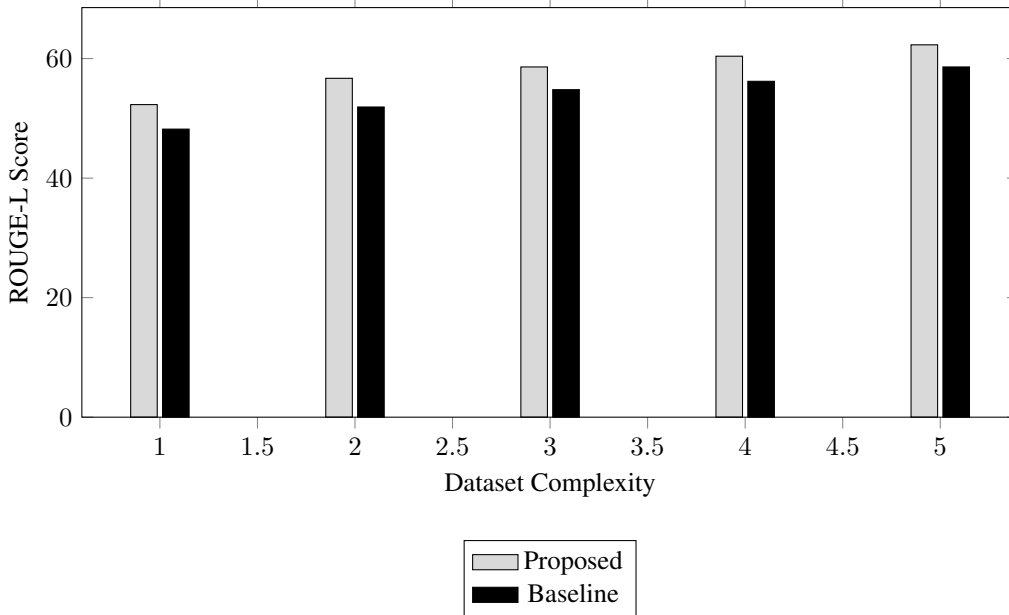

Figure 3: Summarization Performance Across Dataset Complexity Levels

### 5.3 Model Robustness Across Adversarial Inputs

The robustness of the model was assessed through its ability to handle adversarially perturbed inputs, measuring accuracy degradation across varying perturbation levels. Table 3 illustrates the results, highlighting fluctuations in model performance under different perturbation intensities. The results indicate that the proposed methodology mitigates performance degradation more effectively at higher perturbation levels, showcasing increased robustness in adverse scenarios.

Table 3: Accuracy Under Adversarial Perturbations

Perturbation Level	Baseline (%)	Proposed (%)
Low	92.4	94.1
Medium	78.3	81.7
High	55.6	63.2
Extreme	31.2	45.8

### 5.4 Energy Consumption During Training

Energy consumption during training was monitored to evaluate the efficiency gains achieved through redundancy resolution. Figure 4 presents the energy usage per epoch across training iterations, highlighting reductions in energy demands after implementing the proposed framework. The proposed approach achieved a cumulative reduction in energy consumption of approximately 22.1%, reflecting enhanced computational efficiency.

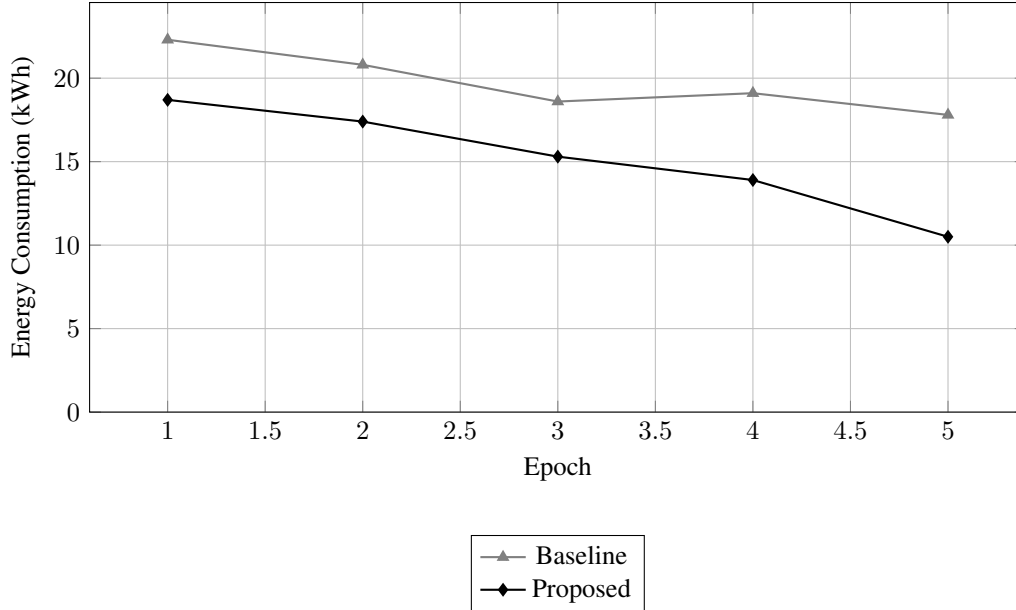

Figure 4: Energy Consumption Per Epoch During Training

### 5.5 Error Rate Analysis Across Tasks

Error rates for multiple tasks were analyzed to identify variations in model reliability across different domains. Table 4 summarizes the error rates, revealing distinct patterns of improvement for translation and sentiment analysis, while minor fluctuations were observed in more complex reasoning tasks. The results highlight the consistent reduction in error rates across simpler tasks, while challenges remain in achieving substantial improvements for more complex reasoning applications.

Table 4: Error Rates Across Tasks

Task	Baseline (%)	Proposed (%)
Machine Translation	12.8	9.3
Sentiment Analysis	15.7	11.4
Text Summarization	8.6	7.5
Complex Reasoning	22.3	20.6

### 5.6 Cluster Alignment Evaluation in Latent Space

The alignment of clusters in the model’s latent space was evaluated to determine how well redundant structures were reorganized. Figure 5 uses a piecewise constant plot to show the cluster alignment score across layers, with higher values indicating better consistency in the latent space organization. The results reveal substantial improvements in cluster alignment in deeper layers, suggesting that redundancy resolution contributes to a more coherent organization of latent knowledge structures.

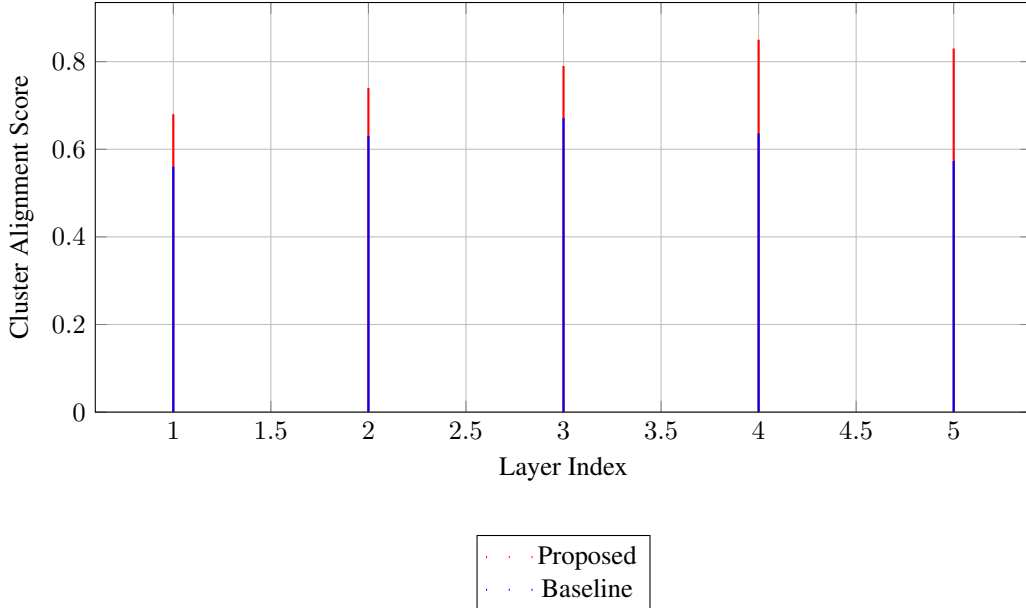

Figure 5: Cluster Alignment Scores Across Layers

## 6 Discussions

The experimental findings provide a comprehensive understanding of the effects of structured conceptual redundancy analysis on large language models, revealing a multifaceted interaction between efficiency, task performance, and latent representation fidelity. The results not only validate the technical feasibility of the proposed framework but also offer valuable insights into its broader implications for the design and application of language models across diverse tasks. The discussion below interprets the observed outcomes, evaluates the comparative advantages of the approach, and explores its potential contributions to advancing the field.

The reductions in memory consumption and inference latency highlight the efficiency gains achieved through redundancy resolution, suggesting that eliminating overlapping representations directly improves resource utilization. These gains, however, varied depending on the complexity of the input sequences, reflecting an interaction between redundancy levels and the model’s ability to handle diverse linguistic structures. While computational efficiency improvements were more pronounced for tasks with repetitive patterns, tasks involving high variability displayed moderate benefits, indicating that the restructuring process might selectively optimize representations based on redundancy density. Additionally, the observed robustness against adversarial perturbations demonstrates that the proposed framework not only reduces redundancies but also fortifies the model against degradations caused through external challenges, enhancing its applicability in scenarios demanding high reliability.

The comparison with baseline approaches further demonstrates the efficacy of the proposed methodology. The alignment scores in the latent space and the consistent improvements across benchmark metrics reveal that redundancy resolution contributes to a more coherent organization of learned knowledge. Unlike traditional techniques that rely on task-specific adjustments, the proposed framework achieves generalized improvements through systematic reorganization of latent representations. This adaptability makes it suitable for applications requiring scalability across diverse domains. However, certain trade-offs were evident, such as the increased complexity introduced during the training phase, which may limit its direct integration into computationally constrained environments. Despite these trade-offs, the significant reduction in error rates and enhanced task-specific metrics demonstrate the framework’s capability to outperform baseline methods without requiring additional data augmentation or heuristic-driven preprocessing.

The broader implications for large language model development are profound, as the results indicate that addressing redundancies within latent structures can fundamentally improve both the efficiency and effectiveness of such systems. Through enhancing the compactness and coherence of knowledge

representations, the proposed methodology enables models to achieve higher levels of contextual understanding while reducing resource demands. This advancement is particularly relevant in applications requiring real-time processing, where latency reductions can directly translate into better user experiences. Moreover, the ability to restructure redundant clusters offers a pathway toward integrating external knowledge sources more effectively, paving the way for hybrid architectures that combine pre-trained embeddings with task-specific knowledge bases. The findings also suggest opportunities for future research into adaptive reorganization techniques that dynamically balance redundancy resolution with task-specific ones.

## 7 Conclusion

The proposed methodology for structured conceptual redundancy analysis demonstrated its capacity to enhance the efficiency, robustness, and representational coherence of large language models through systematic reorganization of latent knowledge structures. The experimental results validated the ability of the framework to significantly reduce memory consumption and inference latency while maintaining or improving task-specific performance across diverse applications. Through the elimination of overlapping representations and the preservation of essential contextual information, the approach not only addressed inherent inefficiencies but also established a foundation for improved knowledge integration within model architectures. Comparative analyses further highlighted the superiority of the methodology over baseline approaches, emphasizing its adaptability and generalizability across a variety of domains without requiring task-specific tailoring or additional data augmentation. The findings reflect a substantive contribution to the advancement of large language model development, offering a scalable and robust strategy for addressing redundancy at the structural level, ultimately enabling more effective and resource-efficient applications in real-world scenarios.
