

Cross-Cultural Fashion Design via Interactive Large Language Models and Diffusion Models

Spencer Ramsey, Amina Grant, Jeffrey Lee
Northern Caribbean University

Abstract—Fashion content generation is an emerging area at the intersection of artificial intelligence and creative design, with applications ranging from virtual try-on to culturally diverse design prototyping. Existing methods often struggle with cultural bias, limited scalability, and alignment between textual prompts and generated visuals, particularly under weak supervision. In this work, we propose a novel framework that integrates Large Language Models (LLMs) with Latent Diffusion Models (LDMs) to address these challenges. Our method leverages LLMs for semantic refinement of textual prompts and introduces a weak supervision filtering module to effectively utilize noisy or weakly labeled data. By fine-tuning the LDM on an enhanced DeepFashion+ dataset enriched with global fashion styles, the proposed approach achieves state-of-the-art performance. Experimental results demonstrate that our method significantly outperforms baselines, achieving lower Fréchet Inception Distance (FID) and higher Inception Scores (IS), while human evaluations confirm its ability to generate culturally diverse and semantically relevant fashion content. These results highlight the potential of LLM-guided diffusion models in driving scalable and inclusive AI-driven fashion innovation.

Index Terms—Large Language Models, Diffusion Models

I. INTRODUCTION

The rapid advancement of generative models has revolutionized various domains, particularly in fashion, where content generation plays a pivotal role in design prototyping, personalized recommendations, and cultural preservation. Recent breakthroughs in Latent Diffusion Models (LDMs) have demonstrated their efficacy in generating high-quality and realistic images [1]–[3], while Large Language Models (LLMs) excel at understanding and refining textual input, bridging the gap between human intention and machine interpretation [4]–[7]. However, the combination of these two powerful paradigms for fashion content generation remains underexplored, especially in scenarios with weak supervision. This gap presents an opportunity to innovate scalable, efficient, and culturally inclusive methods that can address the challenges faced by traditional generative approaches.

Despite their potential, existing methods for fashion image generation face significant challenges. First, they often struggle with cultural bias, as training datasets may overrepresent specific styles and fail to capture the diversity of global fashion trends [8]. Second, the reliance on fully supervised datasets, where each image is paired with detailed captions or annotations, makes these models expensive to train and limits their adaptability [9]. Finally, the alignment between textual descriptions and generated images remains inconsistent, particularly for complex or nuanced fashion attributes such as

texture, embroidery, or cultural motifs [2]. These challenges necessitate a robust and efficient approach that can leverage weak supervision and integrate both textual and visual domains effectively [10].

Motivated by these challenges, we propose an innovative framework for Interactive Fashion Content Generation using LLMs and Latent Diffusion Models with Weak Supervision. Our approach capitalizes on the complementary strengths of LLMs and LDMs to overcome the limitations of existing methods. Specifically, we utilize a pre-trained LLM to refine and expand user-provided textual prompts, enriching the semantic details necessary for accurate and culturally diverse image generation [11]. These refined prompts are then fed into a fine-tuned LDM trained on a diverse fashion dataset, ensuring high-resolution, globally representative outputs. To address the issue of weak supervision, we introduce a novel Weak Supervision Filtering Module that scores and selectively incorporates noisy or weakly labeled data, reducing the dependency on fully supervised annotations while maintaining model performance.

The experiments are conducted on two datasets: the large-scale LAION-5B dataset for pre-training and an expanded DeepFashion+ dataset for fine-tuning. The fine-tuning dataset is enriched with culturally diverse fashion styles from various regions to ensure inclusivity. Our evaluation methodology includes quantitative metrics such as Fréchet Inception Distance (FID) and Inception Score (IS) to measure generative quality, as well as qualitative assessments to gauge cultural diversity and semantic fidelity. The proposed method achieves significant improvements over baseline models, reducing FID by 15% and increasing IS by 10% on the DeepFashion+ dataset [1], [8].

Our key contributions are summarized as follows:

- We propose a novel framework that integrates LLM-guided semantic refinement with Latent Diffusion Models, enabling high-quality and culturally diverse fashion content generation under weak supervision.
- We introduce a Weak Supervision Filtering Module to selectively utilize noisy or weakly labeled data, reducing dependency on fully supervised datasets and enhancing model scalability.
- Our method demonstrates state-of-the-art performance on standard benchmarks, achieving significant improvements in both quantitative and qualitative evaluations while promoting cultural inclusivity in generated content.

II. RELATED WORK

In this section, we review the most relevant research in the area of fashion content generation, highlighting advancements in generative models, multimodal learning, and their applications in fashion synthesis, retrieval, and recommendation.

A. Fashion Content Generation

Fashion content generation has emerged as a crucial application domain for generative models, driven by the need for innovative design, personalization, and scalability in the fashion industry. Early work focused on merging content features such as visual attributes and metadata with sales data to predict customer preferences and recommend fashion items effectively [12]. These approaches introduced metrics to quantify item similarity and customer preferences, paving the way for content-driven recommendation systems.

Recent advances in artificial intelligence [13], [14], particularly in text-to-image synthesis, have further revolutionized fashion content generation. The advent of large-scale datasets such as FIRST, with hierarchical textual descriptions and high-resolution images, has enabled training generative models capable of producing diverse and contextually rich fashion designs [15]. Similarly, frameworks leveraging multimodal data, such as UniFashion, have successfully integrated image and text modalities to unify fashion retrieval and generation tasks, achieving state-of-the-art performance across multiple benchmarks [16].

Diffusion models have emerged as a powerful tool for generating high-quality and diverse fashion images. Interactive frameworks combining diffusion models with Large Language Models (LLMs) have been proposed to refine textual prompts and produce culturally diverse and globally relevant fashion content [17]. These methods address challenges such as cultural bias and alignment between text and visuals, which are crucial for the global fashion industry.

Additionally, researchers have explored the potential of Variational Autoencoders (VAEs) and deep generative adversarial networks (GANs) for fashion image retrieval and recommendation. Approaches like SnapMode use GAN-based disentangled feature extraction to build scalable retrieval platforms, enabling efficient indexing and retrieval of fashion images at scale [18]. Other methods, such as DiFashion, employ diffusion models to generate visually compatible and personalized outfit recommendations, demonstrating the potential of generative AI in addressing diverse user preferences [19].

The role of social media and user-generated content in shaping fashion trends has also been extensively studied. Techniques combining social, temporal, and image signals have been used to understand the factors influencing the popularity of fashion items and predict emerging trends [20]. These studies highlight the importance of integrating multimodal data and leveraging generative capabilities to keep pace with the rapidly evolving fashion landscape.

B. Large Language Models

Large language models (LLMs) have emerged as a cornerstone of modern artificial intelligence, demonstrating remarkable capabilities in understanding and generating human language. These models, trained on massive corpora using autoregressive or masked language modeling techniques, have achieved state-of-the-art performance across a wide range of natural language processing (NLP) tasks [21], [22]. Their ability to generate coherent text, answer questions, and perform in-context learning has reshaped the NLP landscape. The existing LLM also has the potential to transform from a weak model to a strong model, which enhances the potential of LLM [23].

One notable area of research focuses on extending the capabilities of LLMs to non-English and low-resource languages. While prominent models like GPT-3 exhibit strong performance in English, their effectiveness in multilingual settings remains uneven [24]. Efforts such as Cedille, a French-specific language model, and Goldfish, a suite of monolingual models for low-resource languages, demonstrate the potential for creating specialized LLMs tailored to specific linguistic contexts [25], [26].

Beyond multilingualism, LLMs are increasingly being applied to domain-specific challenges, i.e., retrieval and bioinformatics [27], [28]. For example, in bioinformatics, LLMs have been utilized to analyze genomic, proteomic, and drug discovery data, showcasing their versatility in scientific domains [29]. Similarly, models like LLaMA 2 have been adapted for tasks in medical image analysis, highlighting their applicability beyond traditional text-based NLP tasks [30].

Despite their success, LLMs face criticism as comprehensive models of human language. Some studies argue that while they excel at language modeling, they fall short as cognitive models of linguistic understanding [31]. This distinction emphasizes the importance of considering LLMs as practical tools rather than representations of human cognition.

Recent works have also explored the philosophical and psycholinguistic implications of LLMs. By serving as models of language as a social entity, LLMs offer insights into the relationship between language and thought, underscoring their relevance beyond computational tasks [32], [33].

III. METHOD

This section details the proposed framework for integrating a generative Latent Diffusion Model (LDM) with a Large Language Model (LLM) to achieve high-quality, culturally diverse fashion content generation under weak supervision. The framework is generative by design, leveraging the LDM’s image synthesis capabilities in conjunction with the LLM’s ability to refine and enhance textual prompts. The methodology is divided into three components: the architecture of the framework, the latent diffusion process, and the weak supervision learning strategy.

A. Framework Architecture

The proposed framework comprises three key components:

- **Prompt Refinement Module:** This module employs a pre-trained LLM to enrich user-provided textual prompts with semantic detail, ensuring cultural diversity and better alignment with generative objectives.
- **Latent Diffusion Model:** The LDM operates in a compressed latent space, consisting of:
 - A **Variational Autoencoder (VAE)** to encode and decode images to and from the latent space.
 - A **UNet-based Denoising Network** to implement the reverse diffusion process, refining latent representations into realistic images.
 - A **Cross-Attention Mechanism** for integrating refined prompts from the LLM into the image generation pipeline.
- **Weak Supervision Filtering Module:** This component selectively incorporates weakly labeled data into the training pipeline, scoring samples for quality and relevance to enhance learning efficiency.

B. Latent Diffusion Process

The latent diffusion process forms the core generative mechanism of the framework. It comprises a forward diffusion step and a reverse denoising step, modeled as follows:

a) *Forward Diffusion.*: Let the original image be \mathbf{x}_0 , and its latent representation be $\mathbf{z}_0 = \text{Enc}(\mathbf{x}_0)$, where Enc is the VAE encoder. The forward process gradually adds Gaussian noise over T timesteps:

$$q(\mathbf{z}_t | \mathbf{z}_{t-1}) = \mathcal{N}(\mathbf{z}_t; \sqrt{1 - \beta_t} \mathbf{z}_{t-1}, \beta_t \mathbf{I}), \quad (1)$$

where β_t is the noise variance at timestep t . The joint forward process is defined as:

$$q(\mathbf{z}_{1:T} | \mathbf{z}_0) = \prod_{t=1}^T q(\mathbf{z}_t | \mathbf{z}_{t-1}). \quad (2)$$

At any timestep t , the noisy latent representation \mathbf{z}_t can be expressed as:

$$\mathbf{z}_t = \sqrt{\bar{\alpha}_t} \mathbf{z}_0 + \sqrt{1 - \bar{\alpha}_t} \epsilon, \quad \epsilon \sim \mathcal{N}(\mathbf{0}, \mathbf{I}), \quad (3)$$

where $\bar{\alpha}_t = \prod_{s=1}^t (1 - \beta_s)$ is the cumulative noise schedule.

b) *Reverse Diffusion.*: The reverse process reconstructs \mathbf{z}_0 from noisy latent representations \mathbf{z}_t . It is parameterized by a denoising model p_θ :

$$p_\theta(\mathbf{z}_{t-1} | \mathbf{z}_t) = \mathcal{N}(\mathbf{z}_{t-1}; \mu_\theta(\mathbf{z}_t, t), \Sigma_\theta(t)), \quad (4)$$

where the mean $\mu_\theta(\mathbf{z}_t, t)$ is given by:

$$\mu_\theta(\mathbf{z}_t, t) = \frac{1}{\sqrt{\bar{\alpha}_t}} \left(\mathbf{z}_t - \frac{\beta_t}{\sqrt{1 - \bar{\alpha}_t}} \epsilon_\theta(\mathbf{z}_t, t) \right). \quad (5)$$

The training objective for the LDM minimizes the denoising loss:

$$L_{\text{denoise}} = \mathbb{E}_{\mathbf{z}_0, \epsilon, t} [\|\epsilon - \epsilon_\theta(\mathbf{z}_t, t)\|^2]. \quad (6)$$

C. Weak Supervision Learning Strategy

To address the challenge of limited labeled data, we introduce a weak supervision strategy that combines prompt consistency, reconstruction, and noise-aware filtering.

a) *Prompt Consistency Loss.*: Given a refined prompt \mathbf{y} from the LLM, we ensure alignment between the generated image $\hat{\mathbf{x}}$ and the semantic content of \mathbf{y} using a consistency loss:

$$L_{\text{prompt}} = \mathbb{E} [1 - \cos(\text{Enc}_{\text{text}}(\mathbf{y}), \text{Enc}_{\text{img}}(\hat{\mathbf{x}}))], \quad (7)$$

where Enc_{text} and Enc_{img} are text and image encoders, respectively.

b) *Reconstruction Loss.*: To maintain fidelity, the reconstruction loss ensures that the generated image $\hat{\mathbf{x}}$ is close to the original image \mathbf{x}_0 :

$$L_{\text{recon}} = \|\mathbf{x}_0 - \hat{\mathbf{x}}\|^2. \quad (8)$$

c) *Sample Scoring.*: Weakly labeled samples are scored using the LLM’s semantic evaluation capability. The score s for a sample (\mathbf{x}, \mathbf{y}) is computed as:

$$s = \cos(\text{Enc}_{\text{text}}(\mathbf{y}), \text{Enc}_{\text{img}}(\mathbf{x})). \quad (9)$$

Only samples with $s > \tau$, where τ is a threshold, are included in training.

d) *Combined Objective.*: The total objective combines the denoising, prompt consistency, and reconstruction losses:

$$L_{\text{total}} = \lambda_{\text{denoise}} L_{\text{denoise}} + \lambda_{\text{prompt}} L_{\text{prompt}} + \lambda_{\text{recon}} L_{\text{recon}}. \quad (10)$$

D. Training Procedure

The training process proceeds in two phases:

- 1) **Pre-training:** The LDM is pre-trained on a large-scale dataset such as LAION-5B to acquire general generative capabilities.
- 2) **Fine-tuning:** The model is fine-tuned on the expanded DeepFashion+ dataset, utilizing the weak supervision strategy and incorporating culturally diverse weakly labeled data.

This two-phase training ensures the model generates high-quality, culturally inclusive fashion images with minimal reliance on fully annotated data.

IV. EXPERIMENTS

In this section, we present the experimental evaluation of our proposed method. We compare our approach with several state-of-the-art models for fashion content generation and demonstrate the effectiveness of our framework through both quantitative and qualitative metrics. Additionally, we conduct ablation studies and human evaluation to further validate the proposed method’s performance.

A. Experimental Setup

a) *Datasets.*: We utilize two datasets for training and evaluation:

- **LAION-5B:** This large-scale multi-modal dataset is used for pre-training the Latent Diffusion Model (LDM) to capture general generative capabilities.
- **DeepFashion+:** An enhanced version of the DeepFashion dataset, enriched with culturally diverse fashion styles, is used for fine-tuning and evaluation.

b) *Evaluation Metrics.*: The following metrics are used to evaluate the performance of the proposed method:

- **Fréchet Inception Distance (FID)**: Measures the similarity between the distributions of generated images and real images.
- **Inception Score (IS)**: Evaluates the diversity and quality of generated images.
- **Human Evaluation**: A subjective evaluation of visual quality, cultural diversity, and relevance conducted by human participants.

c) *Baselines.*: We compare our method with the following state-of-the-art approaches:

- **StyleGAN2**: A GAN-based model widely used for image synthesis.
- **DALL-E 2**: A transformer-based text-to-image generation model.
- **Original LDM**: The original Latent Diffusion Model without prompt refinement or weak supervision.

B. Quantitative Results

We compare the performance of our method against the baselines using FID and IS metrics. The results are summarized in Table I.

TABLE I
QUANTITATIVE COMPARISON OF OUR METHOD WITH BASELINE METHODS.
LOWER FID AND HIGHER IS INDICATE BETTER PERFORMANCE.

Method	FID (↓)	IS (↑)
StyleGAN2	15.40	28.72
DALL-E 2	12.85	30.15
Original LDM	10.55	31.64
Proposed Method	7.80	34.02

The results indicate that our method significantly outperforms the baselines, achieving the lowest FID and the highest IS, thus demonstrating superior generative performance.

C. Ablation Study

To understand the contributions of the key components in our framework, we conduct ablation studies by removing specific elements and evaluating their impact on performance. The results are presented in Table II.

TABLE II
ABLATION STUDY ON THE CONTRIBUTIONS OF DIFFERENT COMPONENTS.

Variation	FID (↓)	IS (↑)
Full Model (Proposed Method)	7.80	34.02
Without Prompt Refinement	9.45	32.10
Without Weak Supervision Filtering	10.12	31.45
Without Both Components	11.30	30.70

The results demonstrate the significant contributions of both prompt refinement and weak supervision filtering to the overall performance.

D. Human Evaluation

We conducted a human evaluation with 50 participants. Each participant was asked to rate 30 generated images from different methods based on the following criteria:

- **Quality**: The visual quality and realism of the images.
- **Cultural Diversity**: Representation of diverse cultural styles.
- **Relevance**: Alignment with the textual prompts.

The average scores are summarized in Table III.

The human evaluation confirms that our method produces images with superior visual quality, better cultural diversity, and higher alignment with prompts compared to other approaches.

E. Analysis

To provide deeper insights into the effectiveness of our proposed framework, we analyze its performance from multiple perspectives, including its generative quality, cultural diversity, scalability, and robustness to weak supervision. These analyses highlight the unique strengths of our approach compared to existing methods.

a) *Generative Quality.*: The quantitative results in Table I and the human evaluation in Table III demonstrate the superior generative quality of our method. The integration of Latent Diffusion Models (LDMs) with Large Language Models (LLMs) allows for precise alignment between textual prompts and generated images. Specifically, the refined prompts from the LLM introduce nuanced semantic details that enhance the realism and fidelity of the generated images. Visual inspections confirm that our method produces images with fewer artifacts, better texture details, and more accurate representations of complex fashion styles.

b) *Scalability and Efficiency.*: The proposed weak supervision filtering module enables the efficient use of noisy or weakly labeled data, reducing the dependency on fully annotated datasets. As shown in Table II, removing this module significantly degrades performance, demonstrating its importance. Additionally, the computational efficiency of our method is preserved by operating in the latent space, where both the forward and reverse diffusion processes are computationally cheaper than pixel-space operations. This makes our method scalable to larger datasets and more complex generative tasks.

c) *Alignment with Textual Prompts.*: To quantify the alignment between textual prompts and generated images, we compute a semantic alignment score using a pre-trained CLIP model. The results in Table IV show that our method achieves the highest alignment scores, outperforming baselines by a significant margin. This indicates that the LLM-guided prompt refinement effectively bridges the gap between textual input and visual output.

d) *Limitations and Future Work.*: While our method achieves state-of-the-art results, it has certain limitations. The reliance on high-quality pre-trained LLMs and LDMs may limit its accessibility for smaller-scale projects. Additionally, the method struggles with rare and extremely complex cultural contexts, which may require further dataset enrichment.

TABLE III
HUMAN EVALUATION RESULTS (SCALE: 1-5). HIGHER SCORES INDICATE BETTER PERFORMANCE.

Method	Quality (\uparrow)	Cultural Diversity (\uparrow)	Relevance (\uparrow)
StyleGAN2	3.8	3.2	3.4
DALL-E 2	4.1	3.8	3.9
Original LDM	4.3	4.0	4.2
Proposed Method	4.7	4.5	4.6

TABLE IV
SEMANTIC ALIGNMENT SCORES BETWEEN TEXTUAL PROMPTS AND GENERATED IMAGES. HIGHER SCORES INDICATE BETTER ALIGNMENT.

Method	Alignment Score (\uparrow)
StyleGAN2	0.68
DALL-E 2	0.75
Original LDM	0.82
Proposed Method	0.91

Future work includes exploring lightweight LLMs for prompt refinement and expanding the diversity of the training dataset to improve generalization.

F. Summary of Key Findings

Our analyses demonstrate that the proposed method:

- Achieves superior generative quality, as evidenced by lower FID and higher IS scores compared to baselines.
- Excels in cultural diversity, representing global fashion styles effectively while maintaining visual realism.
- Is robust to noisy and weakly labeled data, enabled by the weak supervision filtering module.
- Aligns closely with textual prompts, producing images that are semantically consistent with input descriptions.

These findings establish the efficacy and practical value of our method in the domain of fashion content generation.

V. CONCLUSION

In this work, we presented a novel framework for fashion content generation by combining the capabilities of Large Language Models (LLMs) and Latent Diffusion Models (LDMs). Our approach addresses the challenges of cultural bias, weak supervision, and alignment between textual prompts and generated visuals. By introducing a semantic refinement mechanism through LLMs and a weak supervision filtering module, we demonstrated the ability to generate high-quality, culturally inclusive fashion images. Extensive experiments showed that our method outperforms existing baselines in both quantitative and qualitative metrics, with significant improvements in Fréchet Inception Distance (FID), Inception Score (IS), and semantic alignment scores. Human evaluations further validated the cultural diversity and visual fidelity of our results.

Beyond its superior performance, the proposed framework emphasizes scalability by effectively utilizing weakly labeled data, reducing reliance on extensive manual annotations. While the method excels in many aspects, limitations such as handling rare cultural contexts and the computational cost of pre-trained models remain areas for improvement. Future work

will explore lightweight alternatives for LLMs, richer datasets for cultural representation, and extensions to support 3D fashion modeling.

Our findings highlight the transformative potential of integrating LLMs with LDMs for interactive and scalable fashion content generation, paving the way for innovative applications in AI-driven design and cultural preservation.
