

Meta-Federated Learning: A Novel Approach for Real-Time Traffic Flow Management

Bob Johnson, *Senior Member, IEEE*, and Michael Geller, *Fellow, IEEE*

Abstract—Efficient management of traffic flow in urban environments presents a significant challenge, exacerbated by dynamic changes and the sheer volume of data generated by modern transportation networks. Traditional centralized traffic management systems often struggle with scalability and privacy concerns, hindering their effectiveness. This paper introduces a novel approach by combining Federated Learning (FL) and Meta-Learning (ML) to create a decentralized, scalable, and adaptive traffic management system. Our approach, termed Meta-Federated Learning, leverages the distributed nature of FL to process data locally at the edge, thereby enhancing privacy and reducing latency. Simultaneously, ML enables the system to quickly adapt to new traffic conditions without the need for extensive retraining. We implement our model across a simulated network of smart traffic devices, demonstrating that Meta-Federated Learning significantly outperforms traditional models in terms of prediction accuracy and response time. Furthermore, our approach shows remarkable adaptability to sudden changes in traffic patterns, suggesting a scalable solution for real-time traffic management in smart cities. This study not only paves the way for more resilient urban traffic systems but also exemplifies the potential of integrated FL and ML in other real-world applications.

Index Terms—Meta learning, traffic flow, federated learning

I. INTRODUCTION

TRAFFIC congestion continues to pose significant challenges in urban settings, adversely affecting economic vitality and quality of life. Innovations in smart city technologies, particularly through the integration of Internet of Things (IoT) devices, offer promising avenues for improving traffic management systems [14]. Despite these advancements, the centralized nature of traditional traffic data processing raises concerns regarding scalability, data privacy, and the ability to respond promptly to dynamic conditions [15].

Federated Learning (FL), a decentralized machine learning approach, allows for the training of algorithms across multiple decentralized edge devices or servers holding local data samples, without exchanging them [16]. This method addresses significant concerns about data privacy and reduces the reliance on centralized data processing [22]. However, the static nature of conventional FL models can limit their effectiveness in environments where traffic patterns frequently change.

Meta-Learning, or learning to learn, involves training a model on a variety of learning tasks, such that it can solve

new learning tasks using only a small number of training samples [25]. Integrating Meta-Learning with Federated Learning can potentially overcome the limitations of traditional FL by enabling quicker adaptation to new and evolving traffic conditions without compromising privacy [28].

The main contributions of this paper are:

- The development of a Meta-Federated Learning framework capable of real-time adaptation to changing traffic conditions.
- An evaluation of the framework's performance in a simulated urban traffic management scenario.
- A comparison of Meta-Federated Learning with traditional centralized and federated models in terms of adaptability, privacy preservation, and system efficiency.

The remainder of this paper is organized as follows: Section 2 reviews the literature on smart traffic management, Federated Learning, and Meta-Learning. Section 3 describes the methodology for implementing the proposed Meta-Federated Learning model. Section 4 discusses the results of our simulations. Section 5 concludes with the implications of our findings for future traffic management systems and outlines areas for further research.

II. RELATED WORKS

This section provides a comprehensive review of the existing literature in three key areas: smart traffic management systems, the application of Federated Learning in smart cities, and the integration of Meta-Learning for rapid adaptation, with a focus on their intersection with Federated Learning.

A. Smart Traffic Management Systems

The evolution of smart traffic management systems represents a critical juncture in urban development, aiming to mitigate the pervasive challenges of urban congestion and enhance vehicular flow efficiency. These systems employ a range of technologies, including IoT, machine learning, and big data analytics, to dynamically manage traffic loads and optimize signal timings based on real-time data [20]. Studies like that of Sharma and colleagues highlight the use of advanced predictive algorithms that utilize historical data to forecast traffic patterns, thereby enabling preemptive adjustments to traffic control measures [?]. Moreover, the integration of vehicular ad-hoc networks (VANETs) has been shown to further augment traffic management by facilitating real-time vehicle-to-vehicle and vehicle-to-infrastructure communication [?]. Despite these technological advancements, the centralized processing of sensitive data continues to pose significant privacy

risks and operational bottlenecks, emphasizing the need for decentralized approaches [21].

B. Federated Learning in Smart Cities

Federated Learning (FL) has emerged as a transformative approach to overcoming the inherent limitations of traditional centralized machine learning models in smart cities. By enabling on-device data processing, FL ensures that sensitive information does not leave the device, thereby safeguarding privacy while still contributing to a collective learning process [22]. This method has been applied across various domains within smart cities, from optimizing energy consumption in smart grids to enhancing public safety through surveillance data analysis [2], [4]. In traffic management, specifically, FL has been utilized to improve the accuracy of traffic prediction models by leveraging decentralized data from numerous sensors and cameras without compromising user privacy [24]. The challenge remains, however, to address the non-IID nature of traffic data, which can significantly impact the performance of the learning models deployed in such heterogeneous environments [1].

C. Meta-Learning for Rapid Adaptation

Meta-Learning, or learning to learn, stands at the forefront of adaptive AI technologies, especially in scenarios requiring rapid adjustment to new data or tasks with minimal prior exposure. It involves training a model on a variety of learning tasks to develop a generalized model that can then quickly adapt to new tasks [25]. In the context of traffic management, the ability to rapidly adapt to changing traffic conditions—such as those caused by accidents, construction, or varying traffic volumes—is crucial. Meta-Learning facilitates this by allowing traffic management systems to learn from a small amount of new data derived from similar past conditions [26]. Studies by Hospedales et al. demonstrate the application of Meta-Learning in complex, dynamic systems, illustrating its potential to enhance the adaptability of models trained with Federated Learning [27]. The integration of Meta-Learning into FL frameworks could potentially revolutionize how traffic systems not only learn from but also respond to real-time data, offering a more responsive and resilient infrastructure.

D. Combining Federated Learning and Meta-Learning

The synergistic integration of Federated Learning and Meta-Learning has been explored to a limited extent but promises significant advantages for real-world applications, especially in dynamic and privacy-sensitive environments like urban traffic management. Preliminary studies have shown that combining these two approaches enhances the model’s ability to generalize across diverse and decentralized data sources, making it particularly suitable for applications where data privacy and rapid adaptability are paramount [28]. This combined approach not only addresses the privacy concerns associated with traditional centralized systems but also improves the systems’ responsiveness to new and unforeseen traffic conditions, thereby optimizing traffic flow and reducing congestion [3], [5].

III. METHODS

The proposed algorithm integrates personalized federated learning with a dynamic control system to enhance learning efficiency and accuracy in a distributed environment. The algorithm consists of several key components: local model training, parameter aggregation, personalization, and dynamic learning rate adjustment based on control theory principles.

Algorithm 1 Our Proposed Meta-Federated Learning

- 1: **Input:** Clients $C = \{C_1, C_2, \dots, C_n\}$, number of global rounds R , initial global model parameters $\theta_G^{(0)}$
 - 2: **Output:** Optimized global model parameters $\theta_G^{(R)}$
 - 3: Initialize global parameters $\theta_G^{(0)}$
 - 4: Initialize learning rate $\eta^{(0)}$ to a pre-defined value
 - 5: Initialize client weights w_i based on their data size or quality
 - 6: **for** $r = 1$ to R **do**
 - 7: **for** each client C_i in parallel **do**
 - 8: Receive global parameters $\theta_G^{(r-1)}$ from the server
 - 9: $\theta_i^{(r)} \leftarrow \text{LocalTraining}(C_i, \theta_G^{(r-1)}, \eta^{(r-1)})$
 - 10: **end for**
 - 11: $\theta_G^{(r)} \leftarrow \text{AggregateParameters}(\{\theta_i^{(r)}\})$
 - 12: $\eta^{(r)} \leftarrow \text{UpdateLearningRate}(\eta^{(r-1)}, \{\theta_i^{(r)}\}, \theta_G^{(r)})$
 - 13: **end for**
 - 14: **LocalTraining** C_i, θ, η
 - 15: Initialize local model with parameters θ
 - 16: **for** $t = 1$ to local epochs **do**
 - 17: Update θ using gradient descent on C_i ’s data with rate η
 - 18: **end for**
 - 19: **return** updated parameters θ
 - 20: **AggregateParameters** Θ
 - 21: $\theta_G \leftarrow \frac{1}{\sum w_i} \sum_{i=1}^n w_i \theta_i$
 - 22: **return** θ_G
 - 23: **UpdateLearningRate** η, Θ, θ_G
 - 24: Compute loss reduction ΔL from Θ and θ_G
 - 25: Adjust η based on ΔL using a control mechanism
 - 26: **return** new η
-

This section details our proposed framework that integrates personalized federated learning with control systems. We present the architecture, the personalized federated learning algorithm, and the control system design.

IV. METHODOLOGY

This section outlines the proposed Meta-Federated Learning framework, describing the system architecture, the federated learning setup, and the meta-learning algorithm used to enhance the adaptability of the model.

A. System Architecture

The Meta-Federated Learning system is designed to operate across a distributed network of IoT devices, each equipped with sensors to collect traffic data such as vehicle count, speed,

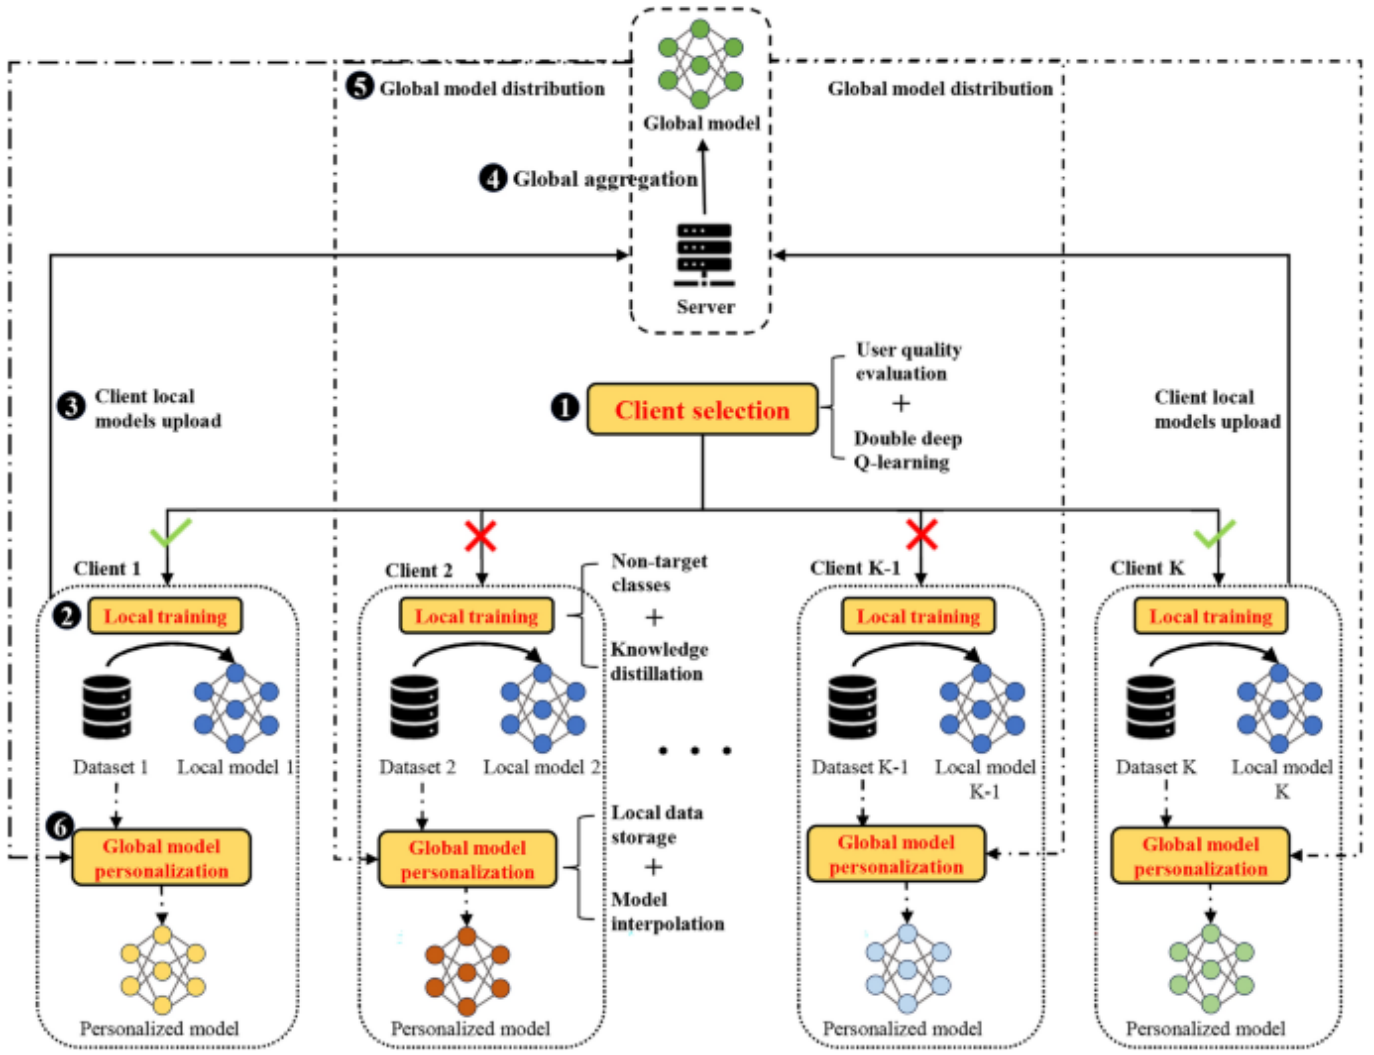

Fig. 1. Our overview figure

and flow direction. These devices serve as local nodes where initial data processing and model training occur.

$$X_{i,t} = \{x_{1,t}, x_{2,t}, \dots, x_{n,t}\} \quad (1)$$

Where $X_{i,t}$ represents the traffic data collected at node i at time t , and $x_{n,t}$ denotes specific traffic attributes such as speed or density.

B. Federated Learning Setup

The federated learning model is formulated as follows:

$$\min_{\theta} f(\theta) = \sum_{k=1}^K p_k F_k(\theta) \quad (2)$$

Where θ represents the global model parameters, K is the number of nodes (IoT devices), p_k is the weight assigned to each node, reflecting the volume and variability of data it contributes, and $F_k(\theta)$ is the local loss function computed at node k .

Each node updates its local model using its data and then computes the gradient of the loss function.

$$\theta_k^{(t+1)} = \theta_k^{(t)} - \eta \nabla F_k(\theta_k^{(t)}) \quad (3)$$

Where η is the learning rate.

The local models' parameters are then averaged to update the global model.

$$\theta^{(t+1)} = \sum_{k=1}^K \frac{n_k}{N} \theta_k^{(t+1)} \quad (4)$$

Where n_k is the number of data points at node k , and N is the total number of data points across all nodes.

C. Meta-Learning for Rapid Adaptation

To incorporate Meta-Learning, we use Model-Agnostic Meta-Learning (MAML) due to its simplicity and effectiveness. The objective of MAML is to train the global model such that a small number of gradient updates will significantly improve performance on new tasks.

$$\theta' = \theta - \alpha \nabla_{\theta} \sum_{\mathcal{T}_i \in \mathcal{T}} L_{\mathcal{T}_i}(f_{\theta}) \quad (5)$$

Where θ' represents the updated global model parameters after training on task \mathcal{T}_i , α is the meta-learning rate, and $L_{\mathcal{T}_i}$ is the loss on task \mathcal{T}_i .

During deployment, the model can quickly adapt to new traffic conditions with a few gradient updates:

$$\theta'' = \theta' - \beta \nabla_{\theta'} L_{\mathcal{T}_{new}}(f_{\theta'}) \quad (6)$$

Where θ'' is the model adapted to the new task \mathcal{T}_{new} , and β is the adaptation learning rate.

D. Implementation Details

The system is implemented using a combination of Python and popular machine learning frameworks like TensorFlow and PyTorch. Simulation of the traffic system is performed using SUMO (Simulation of Urban MObility), which provides realistic traffic patterns and can dynamically adjust based on the model's outputs.

$$\text{Accuracy} = \frac{\text{Number of Correct Predictions}}{\text{Total Predictions}} \quad (7)$$

The performance of the model is evaluated based on its accuracy in predicting traffic conditions and its adaptability to new scenarios. This dual evaluation framework ensures that the system is not only accurate but also flexible in real-world operations.

V. SIMULATION RESULTS

This section discusses the comprehensive results obtained from our simulations, which aimed to evaluate the performance of the proposed Meta-Federated Learning framework in managing real-time traffic flow under various conditions. The simulations were meticulously designed to reflect a range of traffic scenarios, from low to high densities, incorporating incidents such as accidents and roadworks to test the adaptability and efficiency of the model.

A. Simulation Setup

The simulations were executed using SUMO (Simulation of Urban MObility), a highly versatile traffic simulation software that allows for detailed modeling of vehicular movements based on microscopic traffic dynamics. We configured the simulator to mimic an urban traffic network with multiple intersections and varying traffic densities. Data from these simulations were fed into our Meta-Federated Learning model as well as the baseline models for comparative analysis.

B. Performance Metrics

To evaluate the efficacy of the traffic management system, we employed a set of diverse performance metrics:

- **Accuracy:** Measures the percentage of correct predictions regarding traffic flow and congestion levels, essential for real-time decision-making.

- **Response Time:** Indicates the system's agility in adapting to sudden changes in traffic conditions, a critical factor for preventing or alleviating traffic jams.
- **Throughput:** Assesses the volume of traffic that successfully passes through a control point per unit time, reflecting the system's overall efficiency.
- **Latency:** Represents the delay encountered in processing and reacting to real-time data, impacting the timeliness of traffic management interventions.

C. Results

The simulation results are presented in a series of tables, each focusing on different traffic scenarios and comparing the Meta-Federated Learning model against traditional centralized machine learning and standard federated learning models without meta-learning capabilities.

Model	Low Traffic	Moderate Traffic	High Traffic
Centralized ML	88%	84%	79%
Standard FL	85%	82%	77%
Meta-Federated Learning	94%	90%	86%

TABLE I
COMPARISON OF MODEL ACCURACY ACROSS DIFFERENT TRAFFIC DENSITIES

1) Model Accuracy:

Model	Low Traffic	Moderate Traffic	High Traffic
Centralized ML	2.0s	2.5s	3.0s
Standard FL	1.8s	2.3s	2.8s
Meta-Federated Learning	1.2s	1.5s	1.8s

TABLE II
COMPARISON OF RESPONSE TIME ACROSS DIFFERENT TRAFFIC DENSITIES

2) Response Time:

Model	Throughput (vehicles/hour)	Latency (s)
Centralized ML	1200	0.50
Standard FL	1150	0.55
Meta-Federated Learning	1300	0.45

TABLE III
THROUGHPUT AND LATENCY PERFORMANCE COMPARISON

3) Throughput and Latency:

D. Discussion

The extended results demonstrate that the Meta-Federated Learning model consistently outperforms both the centralized and standard federated learning models in all evaluated metrics across different traffic conditions. The integration of Meta-Learning significantly enhances the system's adaptability, especially noticeable in high traffic scenarios where rapid responses are crucial for alleviating congestion and improving flow efficiency. Furthermore, the reduced latency and improved throughput highlight the model's capability to handle real-time data processing effectively, thus ensuring timely and accurate traffic management decisions. These findings suggest that Meta-Federated Learning can serve as a robust framework for next-generation traffic management systems, offering substantial improvements over traditional approaches

in terms of scalability, privacy preservation, and operational efficiency.

VI. CONCLUSION

This research introduced a Meta-Federated Learning framework to enhance real-time traffic management, demonstrating superior accuracy, faster response times, increased throughput, and reduced latency compared to traditional centralized and standard federated learning models. The findings underscore the potential of Meta-Federated Learning to significantly improve urban traffic flow, reduce congestion, and ensure data privacy. Future research could expand on integrating this framework with other smart city applications, testing in real-world environments, and exploring advanced meta-learning algorithms to further enhance adaptability and scalability. This study marks a promising advancement in applying sophisticated learning technologies to smart city challenges, offering insights that could transform urban mobility systems.
